INTERNATIONAL CONFERENCE ON TRAFFIC AND TRANSPORT ENGINEERING

September 27-28th, 2018
Belgrade, Serbia

- ICTTE Belgrade 2018 -
Proceedings of the Fourth International Conference on Traffic and Transport Engineering

ICTTE Belgrade 2018 has been jointly organized by the City Net Scientific Research Center Ltd. Belgrade, University of Belgrade, Faculty of Transport and Traffic Engineering and H2020 project INTEND (Indentify Future Transport Research Needs, GA no. 769638). ICTTE Belgrade 2018 is co-hosted by the AIIT (Associazione Italiana per l'Ingegneria del Traffico e dei Trasporti) Research Center, Rome, Italy and is organized under the auspices of the Italian Society of Transportation Infrastructures (SIIV – Società Italiana di Infrastrutture Viarie) and is held in Belgrade, Serbia, on 27-28th September 2018.

The conference covers a wide range of topics related to traffic and transport engineering, with the aim of representing the importance of all modes of traffic and transport, especially the importance of improving these industries, and their compliance to the most significant principles nowadays, sustainable development and transport efficiency. ICTTE Belgrade 2018 gathers researchers, scientists and engineers whose fields of interest are traffic and transport engineering, and should provide them a good platform for discussion, interactions and exchange of information and ideas. ICTTE Proceedings have been indexed within CPCI - Conference Proceedings Citation Index, a Web of Science™ Core Collection database.

PREFACE - ICTTE Belgrade 2018
Transportation Impact of Industry 4.0...

Ladies and gentlemen, distinguished guests and speakers, dear colleagues and readers,

Traditionally, ICTTE 2018 becomes an event which took place to highlight the remarkable contribution which transportation makes in so many areas of our lives.

A glance through the list of papers and presentations planned for the next two days reveals the amazing diversity of provided research from the universities and laboratories from 30 countries worldwide.

Nowadays, transport has had a profound impact on the way we live and the ICTTE 2018 is pleased to have been a partner in the growth of new technologies, mobility and digitalization era.

Our key role is to make transportation science and technology available to human wellbeing.

Conferences such as this provide a valuable opportunity for research scientists, industry specialists and decision-makers to share experiences.

I am grateful to the many experts who have come to share their knowledge and face challenges in implementation of Industry 4.0.

Abstract: The 21st century brings new trends in Non-cooperative Surveillance technologies. One of them is the Multi-Static Primary Surveillance Radar (MSPSR) technology, which is being widely discussed and just about to be operationally released. ANSPs have a real interest in MSPSR technology as it can be one of the possible solutions to the increasing pressure on the continued operation of existing Primary Surveillance Radars (PSRs). From an ANSP's perspective it is not possible to rely just on the cooperative technologies. There is a need to have at least one non-cooperative back up system due to multiple reasons, such as transponder failures or non-cooperative aircraft. MSPSR can bring 3D surveillance, better precision, coverage in mountainous areas and wind-mill regions, detection of UAV and more. This all leads to importance of evaluation and testing of this technology. As it is very difficult to obtain an MSPSR recording for general scientific community, EUROCONTROL in cooperation with University of Zilina (Air Transport Department) did their research based on current interoperability of Surveillance Analysis Support System for ATC-Centres (SASS-C) tool with MSPSR data and its data simulation. The simulation of the pure MSPSR non cooperative data is based on modification of a WAM recording. Such a recording then can be used for the future analysis. The guide is a partial outcome of the research done on the independent non-cooperative sensors in EUROCONTROL.

Keywords: multistatic, independent, non-cooperative, multilateration, MSPSR.

1. Introduction

The overall topic of Multi-Static Primary Surveillance Radar (MSPSR) is subject to discussions at EUROCONTROL. There is a lot of effort spent on proper documentation and regulation of independent non-cooperative sensors as they show better performance than classical Primary Surveillance Radar (PSR). The new ASTERIX category 15 is right now under development to support Independent non-cooperative sensors (INCS) deployment. The ERA company announced their plan to deploy the first operational MSPSR system in 2018. The approach of EUROCONTROL to this situation was to check the interoperability of their current software equipment with the MSPSR system. As internal analysis of SASS-C compatibility with MSPSR systems that took place in 2017 has shown, the SASS-C is fully capable of handling the MSPSR sensor data. The overall subject of research was held by University of ZILINA in cooperation with EUROCONTROL. As the partial outcome of the research we would like to share the means of simulating MSPSR data in terms of SASS-C software. The simulated data can be used for performance comparison with other technologies or scientific data analysis (Alia et al., 2014). The topic of this article is quite new and unique. Therefore, there are very few scientific publications related to MSPSR subject. We would like to enforce and encourage air navigation services providers (ANSP) and research labs to support the future concept of INCS, providing them with a powerful simulation tool. As EUROCONTROL is the owner of the SASS-C system, we cannot share all sensitive information and principles. The purpose of the article is to share and discuss gathered knowledge with the scientific community.

1.1. SASS-C Brief Description

SASS-C is a surveillance analysis tool that allows verification of surveillance infrastructure performance based on opportunity traffic in a multi-sensor environment. SASS-C is being currently re-engineered into four distinct suites, interoperable through common interfaces. TRES is one of the four suites integrated into the modular architecture of SASS-C V8 (Besada et al., 2008).
TRES has three main roles:

- to reconstruct reference trajectories from opportunity traffic surveillance target reports (OTR),
- to assess ATC surveillance infrastructure performance vs. EUROCONTROL standards (CMP),
- to enable computer-aided identification and investigation of problems of an ATC system (CAI).

1.2. Software Tools for Analysis

The first version of IRIS was developed in 2008 and the development of the version 2 is based upon IRIS v1 development. IRIS is a surveillance data acquisition tool based on SASS-C v6.6 IOSS and RaSta. IRIS is meant to import and record surveillance data by any means supported by SASS-C v6.6 into the Sass-C DataBase (SCDB). After

[1] Corresponding author: nikolas.zacik@fpedas.uniza.sk

the run of IRIS, SASS-C V8 TRES is able to perform reconstruction (OTR module) and analysis (CoMParator - CMP) (Besada et al., 2008)

1.3. MSPSR Principle of Operation

MSPSR refers to a sparse network of transmitters (Tx) and either a single receiver (Rx) or a network of receiver ground stations using static (i.e. non-rotating) antennas. These units receive signals reflected from the aircraft and prepare them for onward transmission to the centralized processing unit. The signal received defines an ellipsoid of constant bistatic range on which the target lies. The location of the transmitter and the receiver are the two loci of the ellipsoid. In the CPU an intersection point of a number of ellipsoids (at least three) is calculated, and this represents the 3-D position of the reflecting target. These systems may use transmitters of opportunity like radio and television broadcast stations, mobile telephone base stations or dedicated transmitters specially deployed to avoid relying on third party illuminators [Kubiková, et al., 2014]. The signal received via the reflected path is cross correlated with the direct signal from the transmitters in order to locate the position of the target reflecting the signals. (ICAO Doc 9924)

2. Methodology

The main condition for simulation of MSPSR data is to choose a proper alternative (existing) data/technology. The chosen technology must be suitable for a future modification to MSPSR final format. This kind of data had to be based on the technologies working on the same geometrical and technical principles as the analyzed MSPSR sensor. For this purpose WAM technology has been chosen as the best available alternative data source (Stevens et al., 2014). So the main condition for the successful simulation of MSPSR data is to use a scenario containing WAM recordings. All further made tests and outcomes of this guide are based on modified WAM data. The main reason for choice of WAM as a data source for this experiment is an analogy in the principles of determination of position by MSPSR and WAM systems. Considering similar geometrical principles of both analyzed technologies, existing WAM data can be modified to any kind of required format where MSPSR data need to be simulated. All systems are using the principle of multilateration for accurate determining of target position (Kubecek and Sterba, 1996). The only difference between those two systems is in the capability of reading information from the received signals. WAM is using cooperative messages (transponder replies) in Mode A/C and S to determine the callsign, barometric altitude, Mode A code and other data provided by the transponder. A WAM position update message can in general contain all this information received from different type of messages. MSPSR on the other hand works as a non-cooperative sensor. Therefore, WAM data can approximate data which could be potentially received from an MSPSR, when the cooperative information is removed (exactly which items should to be removed is described further in this article in the chapter 3). It is important to keep in mind that the mentioned technologies are using completely different technical aspects, signals and principles used for receiving and transmitting the signals. The only common is the geometrical approach of measuring of position. The calculation of the position itself is affected by exactly the same bias and noise principal errors caused by the same geometry (Kubiš and Novák, 2011), (Žáčik and Novák, 2016).

3. MSPSR Simulation Guide

Overall simulation done based on SASS-C VERIF tool should be designed as follows:

3.1. Step 1 –SASS-C VERIF Tool Installation

The first important step is to install the appropriate version of SASS-C VERIF tool and to clarify which version. For the purpose of this analysis we used SASS-C VERIF version: V8.0.E.6.3 (BUILD 1784). This was the most current version of VERIF software supported by SASS-C at the time of writing of this article. The same results of the expertise should be expected in case of using all higher versions based on V8.0.

3.2. Step 2 –WAM Data Record

One of the main requirements for this MSPSR simulation is to import a dataset consisting of WAM data and sensors as it was described and explained in the methodology section above.

3.3. Step 3 – Beginning of the Analysis and Data Modification

This is the most important part of the expertise that must to be followed as it is described below in this document for successful simulation of MSPSR data based on WAM record (Arlery et al., 2015).

It is important to follow exact approach step by step as it is described in this part of the guide, otherwise obtained results may not be relevant. The approach of the experiment is described systematically for the future reproduction as follows:

1. Start IRIS in your “job” folder, which must consist of WAM systems. Then wait until IRIS action will be finished. There are not special requirements for settings in this part.

2. Modify IRIS through a MySQL command which will remove all cooperative information from WAM database. The MySQL command will therefore modify all cooperative (such as identification) and not relevant data from the SD_MLAT table where all the WAM data is stored. Data further needed for the purpose of she simulation you can find in the Table 1 (Garcia, et al., 2014). All other data which are not mentioned in the table have to be removed. Complete list of data available from WAM systems (that are stored in the SD_MLAT table) can be found in the "EUROCONTROL Specification for Surveillance Data Exchange all-purpose structured EUROCONTROL surveillance information exchange" (ASTERIX) Part 14 Category 20 Multilateration Target Reports" (Cabalkova et al., 2014).
Important note: The MySQL command described in the Appendix no 1. needs to be executed BEFORE running of OTR action

Table 1
Items Needed for MSPSR Data Simulation

Data items to keep	Status
DS_ID	Mandatory
REC_NUM	Mandatory
REC_TIME_POSIX	Mandatory
REC_TIME_MS	Mandatory
REPORT_TYPE	Mandatory
TOD	Mandatory
POS_LAT_DEG	Mandatory
POS_LONG_DEG	Mandatory
POS_DOP_X POS_DOP_Y POS_DOP_XY POS_STD_DEV_X_M POS_STD_DEV_Y_M POS_STD_DEV_CORRELATION_COEFF	Recommended Possible to set to null value, but those parameters have significant impact to RRT. In case of removing of this parameter RRT works only for few tracks. Because of bias filtering many plots are skipped. In case of removing of this POS items, it is necessary to set BIASes manually to get relevant results.

Source: Author/ SASS-C

The evaluation of the impact for all items contained in the ASTERIX part 14 cat 20 has been based on their definition provided in the EUROCONTROL documents: "EUROCONTROL Specification for Surveillance Data Exchange ASTERIX Part 14 Category 20 Multilateration Target Reports", "SCDB External Interface Requirement Specification" and "Technical specification for WAM system". The presence of each item in the simulated database has been properly discussed with SASS-C experts. Afterwards the impact of each item modification was properly tested in the first phase of the experiment (Arlery et al., 2015). The outcome of this simulation is the table of reduced data items as it is described in the Table 1.
All items summarized in the Table 1 represent just pure geometrical data of the detected targets. This represents a basic database of MSPSR data. If only data as described in the Table 1, are used, we can confidently clarify that original WAM sensors behave as MSPSR technology in the modified scenario (Cabalkova and Plsek, 2016).

3. In case that only "Mandatory" data from SD_MLAT table are used, it is need to pre-set the SASS-C accuracy and noise limits manually. You can find them in the "Data sources" table. This action has to be done for all defined WAM sensors before running OTR action. Here it is important to mention that removing position accuracy items (POS) has significant negative impact on OTR/ RRT reconstruction (Smith et al., 2006). (RRT - Reference Reconstructed Trajectory) In case that both, "Mandatory" and "Recommended data" are used, there is no required change of default accuracy and noise limits. They will be given by the system itself and the accuracy of RRT result will be significantly better in comparison with scenario where "Recommended data" are not used for reconstruction. For both possible solutions it is important to configure the OTR parameters to ensure that only WAM sensors (which should be already modified in this step) will be used for OTR reconstruction to get desired results. Other sensors should to be kept only for BIAS estimation to improve result accuracy (Chernyak 2009), (Bugaj, 2012).
Run OTR action. Be aware that running of OTR on the modified dataset can take very long to execute. Due to high processor load you should expect more than two hours OTR processing, depending on the amount of data fed and the available computing power. It is not possible to run more than one OTR at the same time, because the previous one will be automatically corrupt with an error code 137 (Conversano, 2011). Graphical examples of different results achieved in case of scenario with not modified data compared to scenario where data has been modified to contain only "Recommended" items as it is described in this document you can see in the figure no. 1 – 2 .

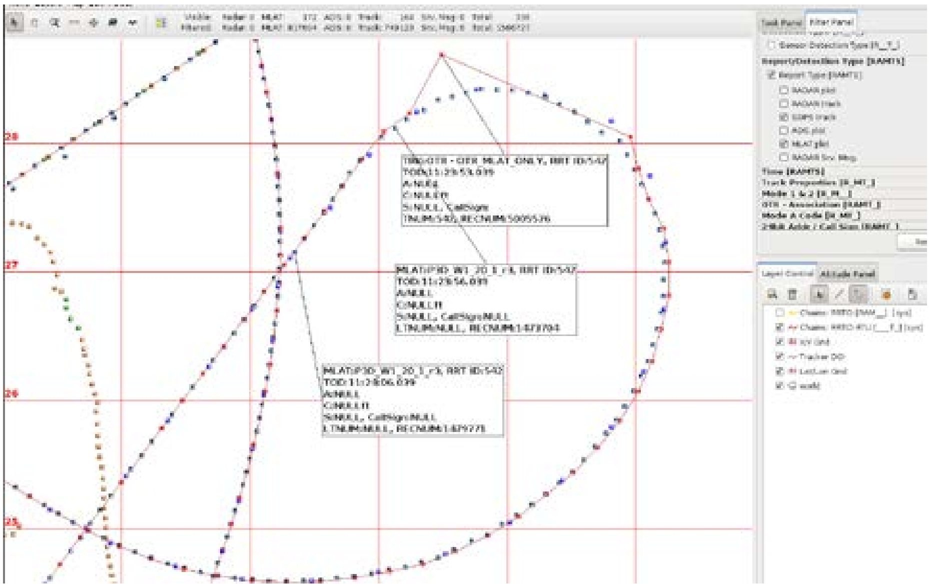

Fig. 1.
RRT Example from Simulated MSPSR Scenario
Source: Author/ SASS-C

In the figure no. 1 you can see an example of tracks on the SASS-C display after the data modification has been done. As you can see OTR chaining is working without problems. On the labels you can observe that all identity data has been removed but all plots are properly chained. This data represents simulated MSPSR data based just on the geometry retrieved from WAM detection. As detail parameter analysis has shown us, chaining observed in the SASS-C is working perfectly. In this case "Recommended" items have been kept as it is described in this document. As you will see in the next figure, the air situation displayed here is almost the same as in the case where data is not modified.
Although in some very rare cases OTR associating was not working because of crucial modifications of the dataset. This problem was observed just in very few cases (less than 2%) and it could cause uncertainties in some specific situations. Until the date of the writing there is no explanation for this rare phenomenon but this problem will be subject of the deeper analysis in the future.

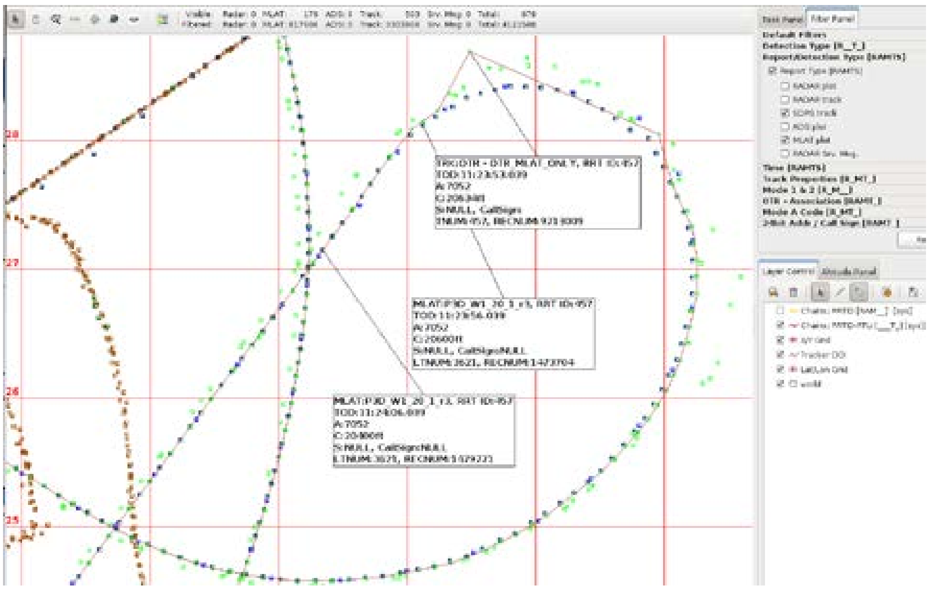

Fig. 2.
RRT Example from not Modified WAM Scenario
Source: Author/ SASS-C

In the figure no. 2 you can see the same airspace situation as it is displayed by OTR in the figure 1 although without modification. It means all contributing devices take part on the detection during this test. As you can see all identity information and all others parameters are visible on each label. OTR chaining is based on pure WAM data obtained from the sensors. That includes contributing data from secondary radars, Mode S and ADS-B (automatic dependent surveillance – broadcast). In comparison with modified scenario there is no difference in the functionality of OTR which means that OTR is working in the same way for both scenarios. Therefore OTR algorithm is able to handle data

based on pure geometry and to chain all plots generated by all targets even if identity of the target is unknown. It means that the modified MSPSR record is still valid and can be processed by any verification or simulation software which was previously configured to handle WAM data.
According to OTR data verification procedure and results obtained from the deeper analysis of simulated MSPSR data we can confirm the simulated data as consistent and valid. According to asterix items used for MSPSR data we can also confirm that only non cooperative geometrical data was used. The same data would be possibly available through any kind of MSPSR record in line with new ASTERIX category 15 designed for INCS. If we will consider that in the previous test the same record was used, we can compare the numbers of total tracks in both tests.

4. Summary

As you can see in the figures, the simulation of MSPSR data based on WAM record is possible just by simple modification of the core data. As SASS-C analysis confirmed, OTR reconstruction of the track is possible even without cooperative and identification data. The test shows that SASS-C is capable to work with pure geometry data as it is summarized in Table 1 which is something that has never been tested before. The same data items/ geometrical information as it was used for this analysis would be possible to obtain from MSPSR technologies [Garcia et al., 2014]. SASS-C verify the complexity and validity of each dataset before its proceeding. If the data set is not valid or some important information is missing, OTR algorithm cannot be successfully executed. In the majority of cases, OTR results obtained from the analysis either based on data modification to MSPSR or based on the original MLAT data, are exactly the same. The only difference was observed in the amount of tracks generated by OTR. Although in few cases OTR algorithm is not working as it is supposed and system is not able to chain the existing plots (Leonardi et al., 2009). There is no clear explanation to why this phenomenon occurs but we have received better results with manual preset of the accuracy thresholds as an emergency solution. The general assumption is: too strict automatic pre-set of the filters results in filtering of data which do not match sufficient requirements defined for MLAT plots (Matousek and Ochodnicky, 2006). Now we are in the phase of designing new MSPSR ASTERIX category which would allow SASS-C to set up all filters and thresholds for the given category, without user interaction with the system (Kalasova et al., 2015). This solution could prevent problems with OTR filtering in case that our assumption is correct.

5. Conclusion

According to the outcomes of the experiment we can confidently clarify that SASS-C is well prepared for MSPSR technologies and is capable to handle that kind of data. The first intent was to start the development of the algorithm compatible with MSPSR directly. There was no assumption that SASS-C or any other software could be able to handle data without identity information because the algorithms were never meant for this purpose .
But as an analysis show us, the amount of reconstructed RRT samples which has been achieved in this experiment for simulated MSPSR sensors (based on SD_MLAT modifications) has been nearly the same as was achieved in case of not modified MLAT data.
The comparison of the results you can see in the figures 1-2 in this article. The only condition to achieve exactly the same results is to use all accuracy items from SD_MLAT table (POS parameters). Otherwise the user interaction and input of the filters is required to achieve the relevant results. All outcomes are demonstrated in the figures in this article, together with verified guide for simulation of MSPSR and pure data that can be used by all SASS-C users for the future simulations and analysis. The main reason for this analysis is that proper ASTERIX category for MSPSR data is not designed yet and the design itself is a topic of many discussions nowadays. Although, new technologies are already deployed and prepared for testing (some of them ready to work in operational conditions). This guide provides a great advantage to test operational functionality and behavior of simulated MSPSR and sensors based on analysis of simulated data before its deployment. The guideline can be used in the same way for SASS-C Prediction tool where you can design a whole virtual network with all desired sensors and evaluate its functionality and predicted accuracy (Zacik, 2017). New categories will be officially implemented to both SASS-C tools as soon as the ASTERIX categories will be designed and officially issued. The complete detailed documentation of the experiment is a property of EUROCONTROL and can be required by all the SASS-C users.

EFFECTS OF UNWANTED TRACKING BOXES IN A REMOTE TOWER CONTROL ENVIRONMENT

Jörn Jakobi[1], Kim-Laura Meixner[2]

Abstract: In the field of air transport operations, "Remote Tower" is a fast-growing concept offering more cost-efficient Air Traffic Services (ATS), mainly for small aerodromes with low traffic volumes. It primarily relies on camera sensors at the aerodrome, producing a video stream, which is relayed to an ATS facility situated independent from the real Tower, where it is usually displayed on a video panorama, in order to replace the direct out-of-the-Tower-window view. This offers the opportunity to provide ATS to more than one airport from a centralized ATS facility, also called Remote Tower Center. By such a center, the critical resource "Air Traffic Control Officer" (ATCO) can be utilized much more cost-efficiently since the ATCO can now control multiple low density aerodromes, sequentially or even simultaneously. To maintain or even increase the ATCO's situational awareness, augmentation features are introduced, such as automated tracking of the traffic the ATCO is responsible for. However, a tracking function is never reliable by 100% and with reference to the signal detection theory, gains and losses are to be expected. This paper investigates the minimum performance parameter of a tracking function in a Remote Tower environment to gain ATCO's acceptance and positive effects on her/his situational awareness and workload. In a human-in-the-loop real time simulation, seven ATCOs performed a realistic traffic scenario. The study was conducted at Remote Tower laboratory at DLR in Braunschweig. By four test conditions the performance of the visual tracking was varied by the number of unwanted tracking boxes: (1) no visual tracking (baseline), (2) low, (3) medium, and (4) high. The findings show that ATCOs very much appreciate visual tracking augmentations. ATCOs can more easily detect critical traffic situation, which increases their situational awareness and safety. Further on, acceptance is rather high and workload on a moderate level and both parameters behave rather robustly, even when the number of unwanted tracking boxes increases.

Keywords: remote tower, tracking, signal detection theory.

1. Introduction and Background

"Remote Tower" is a concept allowing air traffic control officers (ATCOs) to provide control to an airport remotely, independent of their conventional control Tower position. All information the ATCO usually needs to perform her/his job is relayed to a controller working position (CWP) that can be hundred kilometres away from the actual airport. Preferably, several other small airports are connected to such a location that would then be called a Remote Tower control center (RTC). Since particularly small airports due to very occasional traffic suffer cost-efficiency. Thus, a RTC has the advantage to provide more cost-efficient air traffic control (ATC). Out of a pool of available ATCOs, the allocation of ATCOs to airports can be conducted much more efficiently; the ATCOs work at the airports where the traffic happens. With more complex traffic, one, two or more ATCOs provide ATC to one airport but also one ATCO can be in charge of one, two or more very less frequented airports. Core of such a RTC and particularly for each CWP is the camera sensors based on visual presentation of the conventional out-of-the-Tower-window view, usually presented through a panorama video wall. Such a video view of the outside world offers another advantage: Additional ATC relevant information can be superimposed, or augmented, on the real scenery. Information, related to weather or wind for instance, or even flight plan or track data are usually available head down only. With Remote Tower, apart from the head-up outside view, this visual information can now be spatially and timely linked to the video scenery. Hence, head-down times are reduced and the ATCO can capture all relevant ATC information with one gaze. One of the most promising augmentation features is the tracking and indication of surrounding traffic.
Such an automatic tracking function reads out the camera sensor information, associates groups of image pixels with real world objects by image processing, detects moving objects, tracks them and provides an object indication, e.g., a box capturing the moving object (EUROCAE, 2018). If the aerodrome is equipped with additional surveillance sensors, like approach or surface radar, the quality of the tracking function can be further improved with that information. Particularly in far distance when neither ATCOs nor camera sensors are able to detect and track traffic, the radar captures the traffic and track information can be indicated on the video panorama. When the aircraft comes closer also the camera sensors would capture the aircraft and camera and radar track information are to be fused to provide again one single track. Radar and camera sensors complement each other very well, because radar has a much higher coverage range (up to 25 miles) than cameras. Cameras on the other side provide much better spatial accuracy and a much higher update rate. That is, even when provided with a low update rate and low position accuracy, ATCOs know right in advance about traffic in far distance. When the ATCO becomes in charge of traffic in closer vicinity, cameras provide more accurate position information. Another advantage of a tracking function is the labelling function. As soon as the position and identification of an aircraft or vehicle is known to the system, label information stemming from cooperative radar or flight plan information can be linked to the object. Call sign information, aircraft type, altitude, speed or destination information could be provided by a label attached to the object.

[1] Corresponding author: joern.jakobi@dlr.de

In the past, such automated tracking functions were investigated in several national and European research projects with concordant results: Tracking information is very much appreciated by the ATCOs. In the project "Advanced Remote Tower" (ART) of the 6th European Framework Program (Van Schaik et al., 2016a&b) and with the SESAR project P06.09.03 (SESAR, 2014a) ATCOs in an active shadow mode setting were presented tracking information captured from an aerodrome 100km away from their ATCO working position under test. Within the ART project, ATCOs complained about some quality issues, e.g., jumping tracking information, but the majority of the ATCOs appreciated tracking information. In the SESAR project 06.09.03, ATCOs' opinions resulted in an over-average acceptance score of 4.03 on a Likert scale from 1 "strongly disagree" to 5 "strongly agree". Also subjective "trust" and "situation awareness" (SA) measurements scored over-average high. Regarding safety, the ATCOs admitted that "Remote Tower environment can have features that a local tower does not have, including the addition of technical enablers such as tracking overlays". In SESAR project 06.08.04 (SESAR; 2014b), tracking and labelling information was investigated in a multiple Remote Tower setting. In a real time simulation, ATCOs worked a very heavy traffic scenario with 30 movements per hour via a single airport (baseline condition) and the same traffic scenario spread over two airports on a multiple Remote Tower CWP (treatment factor) via two factor levels, with and without automated tracking function. In accordance to SESAR (2014a), the tracking was appreciated as 'nice to have', but was, contrary to SESAR (2014a) results, hardly been used. The authors explained this effect by the high traffic load that led ATCOs to work head down predominately to get ATC relevant information and to operate the electronic flight strips. Papenfuss & Möhlenbrink (2016) tested 12 ATCOs in a simulated Remote Tower environment with automated tracking and assessed their eye-point of regards. By the means of tracking, head-down times could be significantly reduced. ATCOs also regarded the tracking functionality as helpful, particularly in critical situations.

Even when past results could show that augmented tracking information are much appreciated by the ATCOs to increase their SA, there is also a risk that ATCOs get distracted by tracked objects that are not of interest to the ATCO or that the tracking function misses to track an object that is of interest to the ATCO. Both effects decrease the ATCO's SA, can cause additional workload and even safety risks. Wickens (2002) describes these effects in its signal detection theory (SDT). Core of the SDT is a "signal", which is to be detected, can be present or absent when it is detected. If the signal is really present, the SDT speaks of a "hit"; if it is absent, the SDT names it "false alarm". Present signals that are not detected are "misses" (1-p(hit)). The SDT result pattern can be applied for our automated tracking function (see Fig. 1).

	Object of interest	Object not of interest
Object tracked	Wanted → overtrust? → learnt carelessness	Unwanted → negative influence on acceptance, workload or Situation awareness?
Object not tracked	Missed → Safety critical?	Correct Rejection

Fig. 1.
Result Pattern of the Automated Tracking Function and its Associated Effects with Respect to the Signal Detection Theory

To minimise negative (amber colour in Fig 1) and maximise positive effects (green colour in Fig 1) the tracking function must be tuned in an optimal way. It must be sensible enough to keep the "missed" on a low level but also sensitive enough to keep the "unwanted" on an operationally reasonable level (see also Friedman-Berg, 2008). In a nutshell, the minimum performance of the tracking function must be high enough to gain operational benefits. Past research could show that the tracking function can provide operational benefit in a Remote Tower context but the quality of the tracking function has never been varied in an experimental setting to gain knowledge about the minimum operational performance. For the future, this knowledge would help to better tune the function to the local operational needs, to support the standardisation process and to reduce the implementation time. The research question of this study therefore reads: What is the minimum acceptable operational performance of a tracking function in a Remote Tower Control context to provide positive effects on SA and workload.

2. Experimental Design

2.1. Participants

Seven male ATCOs between 29 and 62 years (M = 42.1, SD = 12.8) took part in the experiment. Except of one they all held an active ATC license and work or worked for various air navigation service providers (Austrocontrol, LFV, AVINOR, NATS and ROMATSA). ATCOs were directly invited by an invitation letter and they supported the study voluntarily and without any monetary compensation. All ATCOs and pseudo-ATCOs were familiar with the Remote Tower concept. The written and spoken language was English.

2.2. Experimental Platform

The experimental study was carried out at the Apron Tower Simulator at the Remote Tower laboratory at DLR Braunschweig between 15th and 31st of May 2017. A 45 minutes lasting traffic scenario at the Braunschweig-Wolfsburg airport (EDVE) was prepared to be used in a real time simulation. EDVE is a controlled regional airport with class D control zone (CTR), 2200 feet altitude. The simulated scenario reflected typical day-to-day traffic with 17 total movements (15 VFR and two IFR movements), amongst them two aircraft performing right-hand traffic patterns, four arrivals, seven departures and four CTR crossers. Furthermore, two abnormal traffic events were induced, a maintenance car, which crossed the runway during a simultaneous departure event without waiting for an ATC clearance and one CTR crosser was flying through the CTR from north to south without receive/transmit radio communication (R/T) and without a clearance. Visibility was CAVOK without any clouds. Wind was calm, 260 degrees, five knots and runway 26 was in use. All communication was done via one radio channel and also VFR communication was done in English, because of the international ATCO test sample. Each ATCO controlled the traffic alone, no coordination with apron control or approach control was needed. In- and outbound traffic called directly before entering CTR (VFR), or IFR, when established on final 10 miles out, respectively, outbound traffic requested start-up or taxi. The traffic was operated by two blip pilots, one responsible for arrivals and crossers, one for departures and traffic patterns. The ATCOs was provided with 200 degrees northwards out-of-the-window view and a 360 degrees pan-tilt zoom camera (PTZ). The CWP should simulate a very basic Remote Tower equipage, therefore they were neither provided with 360 degrees panorama nor with approach or surface radar. Head down, they were provided with a tower flight data processing system to operate the flight strips, a space mouse to operate the PTZ, a communication display and an information data processing system (IDVS), providing visibility, wind and QNH information. The automated tracking function was realised with cyan-coloured boxes. There were "wanted" and "unwanted" boxes (see also Fig. 2).

Fig. 2.
Experimental Set Up of the Remote Tower CWP with "wanted" and "unwanted" Tracking Boxes (two left boxes are "unwanted", the right hand box, capturing the departing aircraft is "wanted"

2.3. Test Variables and Test Procedures

The reliability of automated tracking function is related to the relation of "wanted" to "missed" boxes and the amount of "unwanted" boxes. To keep the experimental design efficient and manageable, the relation of "wanted" to "missed" boxes was kept stable. On the other hand, the amount of "unwanted" boxes was varied over the test conditions. Because a perfect 100% "hits" system is very unlikely in an operational environment, the "wanted" hits were fixed on a reasonable value: 15 out of 17 movements were permanently tracked while two out of 17 movements were permanently untracked, which resulted in a 88% hit rate. This hit rate perfectly corresponds to a recommendation of ATCOs out of the international EUROCAE working group WG-100 (EUROCAE, 2018) who proposed a minimum "hit" performance of 85%. What is "wanted" to be tracked is also dependent on the local operational needs, but for this experiment, it was assumed that all aircraft and vehicles on the movement area and in the vicinity of the airport shall be "wanted" targets to be tracked. The amount of “unwanted” boxes instead was selected as the independent variable (IV-A) and was varied over three factor levels A1, A2 & A3. A fourth test condition worked as a baseline condition (BL) in which the automated tracking function was switched off. The appearance of the “unwanted” boxes were varied over four dominant operational locations (runway, taxiway, traffic pattern and final approach area) and over their dwell time, the time the “unwanted” boxes lasted until they disappeared by themselves (2, 5, 30 seconds). The amount of them was varied over the factor levels A1, A2 & A3, whereas A1 should represent a very reasonable and acceptable amount of “unwanted” boxes, A2 should represent a medium amount and A3 a very annoyable amount of “unwanted” boxes. The right choice of the amount of “unwanted” boxes was very important to avoid bottom and ceiling effects in order to be able to judge about the minimum acceptable performance of “unwanted” boxes in the end. In a pre-trial with a Norwegian AVINOR ATCO the amount of “unwanted” boxes was optimally tuned to meet this prerequisite. Table 1 represents the final setting of the amount of “unwanted” boxes.

Table 1
Independent Variable A and its Variation over the amount of “Unwanted” Boxes in the 45 min lasting traffic scenario

Location →	Runway				Taxiway				Final Approach				Traffic Pattern			
Dwell time ↓	**BL**	**A1**	**A2**	**A3**	**BL**	**A1**	**A2**	**A3**	**BL**	**A1**	**A2**	**A3**	**BL**	**A1**	**A2**	**A3**
30 sec	0	0	0	7	0	0	7	14	0	0	0	7	0	0	0	7
5 sec	0	0	7	14	0	7	14	28	0	7	7	14	0	7	7	14
2 sec	0	14	28	42	0	14	28	42	0	14	28	42	0	70	140	210

All test conditions (Baseline, A1, A2, A3) were run with the same traffic scenario to allow a final deduction on the IV-A “amount of unwanted boxes” with respect to measured effects on the dependent variables: Acceptance, SA and workload. To avoid ATCOs’ recognition and training effects caused by a fourfold repetition of the traffic scenario, the aircraft’s call signs were varied over the four different test conditions. The timing of the intruders (runway crossing vehicle and CTR crosser) and the two “missed” boxed movements were alternated as well. The sequence of the test conditions was randomized over the seven ATCOs to eliminate systematically learning or fatigue effects.
The procedure of the study was structured in three parts. The briefing and training phase represented the part in which ATCOs provided demographical date, were informed about the data protection procedure and prepared for the actual experiment. Secondly, the experimental phase corresponded to the conduction of four successive test runs and the third part dealt with completion of the post-run questionnaire and a final debriefing phase. The ATCOs were kept unaware of the actual test condition. During the experimental phase, the ATCOs’ workload, SA and acceptance were assessed. Workload was subjectively measured by I.S.A., a 5-point Likert scale, which popped up every 5 min at the IDVS requesting the ATCO to assess her/his current workload by pressing a button reaching from 1 “under-utilised” until 5 “excessive” (SESAR, 2012). At the same time, the ATCO was requested to subjectively judge about her/his acceptance of the tracking function by the statement: “During the past five minutes I found the tracking boxes: 1 = „Disturbing“, 2 = „Not of interest“, and 3 = „Helpful“”. Moreover, SA and workload were assessed every nine minutes by the SARA-T online questionnaire (Kraemer & Süß, 2015). Regarding the abnormal events, the experimenter noted if the intruders were recognised by the ATCO and how they dealt with them. During the debriefing phase, the ATCOs were asked to fill in standard questionnaires with respect to SA (SASHA), workload (AIM) and Acceptance (SATI), a test battery developed by EUROCONTROL in its project “Solutions for Human-Automation Partnerships in European ATM” (SHAPE) (Dehn, 2008). Further on, the ATCOs provided answers to several closed statements regarding SA, workload and acceptance and were given the chance to provide additional comments and remarks which they eventually had in mind after a full day of testing the automated tracking function.

3. Results

In order to get reasonable result with an acceptable external validity, a sample size of experts was aimed for. A potential drawback with expert sample sizes is the availability of experts. By consequent, the sample size often lacks a reasonable size to apply parametric inference statistics with an acceptable internal validity. The analysis therefore focussed on the descriptive analysis of the results and when appropriate, non-parametric inference statistics like the Friedman or binomial test were applied.
Regarding workload, neither mid-run ISA and SARA-T nor the post run AIM provided significant results by a Friedman test and also the mean values do not draw an easily interpretable pattern. In general, workload is rather under-average and rather unaffected of the treatment (compare Fig. 3).

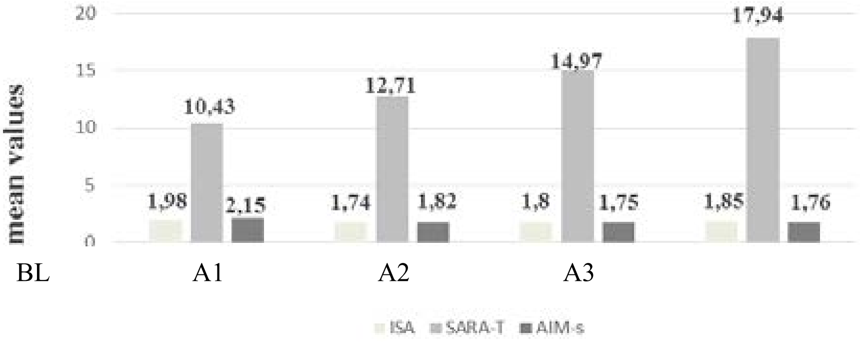

Fig. 3.
Mean values of the Workload measurement metrics ISA, SARA-T and AIM

A similar result was obtained with respect to SA measurements. Neither the mid-run SARA-T nor the post-run SASHA provided a significant result pattern. For SASHA following mean values (M) and standard deviation (SD) were measured: BL = 4.48/.98; A1 = 4.74/.78; A2 = 4.83/.77 and A3 = 4.93/.71. With SARA-T it was measured BL = 4.39/1.89; A1 = 3.47/.76; A2 = 4.51/2.52 and A3 = 4.65/2.96.
According the ATCOs' acceptance, the mid-run assessment via a three-point Likert scale with 1 = „Disturbing", 2 = „Not of interest", and 3 = „Helpful", revealed an overall over-average acceptance but without any significant deviation between the test conditions: A1 = 2.84/.2; A2 = 2.86/.2 and A3 = 2.8/.24 ($\chi^2(2) = .353$, $p = .838$). Same pattern with the SATI post run questionnaire: A1 = 4.29/1.27; A2 = 4.14/.77 and A3 = 3.60/1.07. Actually, acceptance decreases with higher amount of "unwanted" boxes but not significantly. Post-run the ATCOs were also asked: "The experienced wanted, missed and unwanted Boxes had an acceptable rate to help me increasing my situational awareness." and "I experienced unwanted boxes (nuisance boxes) but they popped up in an acceptable amount that did not prevent me from working in a safe and efficient manner" to be answered on a 6 point Likert scale from 1 "strongly disagree" to 6 "strongly agree". Both statements were answered over-average positive and after having conducted a binominal test, A1 and A2 with the first question, and A1 with the second question, became significant ($p = .016$) (see Fig 4).

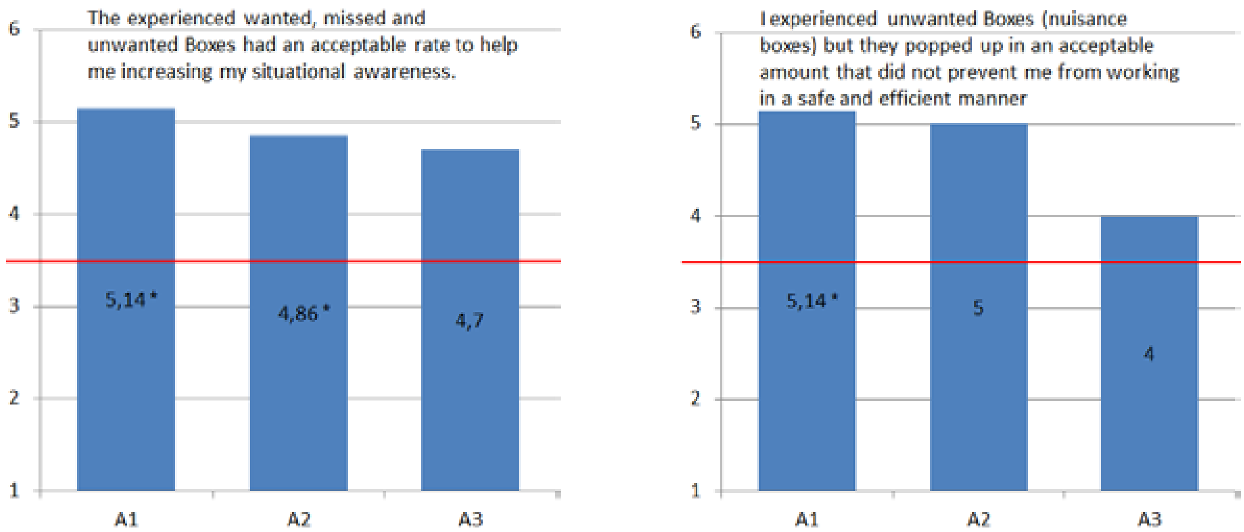

Fig. 4.
Post-run Questions regarding acceptance assessment
Rem.: An asterisk symbol marks a significant over-average value tested by a binominal test with p = .016.

With respect to the two abnormal events: The CTR crosser was not recognised at all it in the BL condition but four of seven ATCOs spotted it in the tracking conditions. Similar results were gained with the vehicle crossing the runway without clearance, which in the BL conditions was seen by four out of seven ATCOs but in the tracking conditions was seen by all ATCOs.
After performing all test runs, the ATCOs were asked 11 further general statements to the automatic tracking function to be answered on a 6-point Likert scale from 1 "strongly disagree" to 6 "strongly agree". Fig 5 shows the mean values and when marked with an asterisk became significant by a binominal test with $p = .016$.

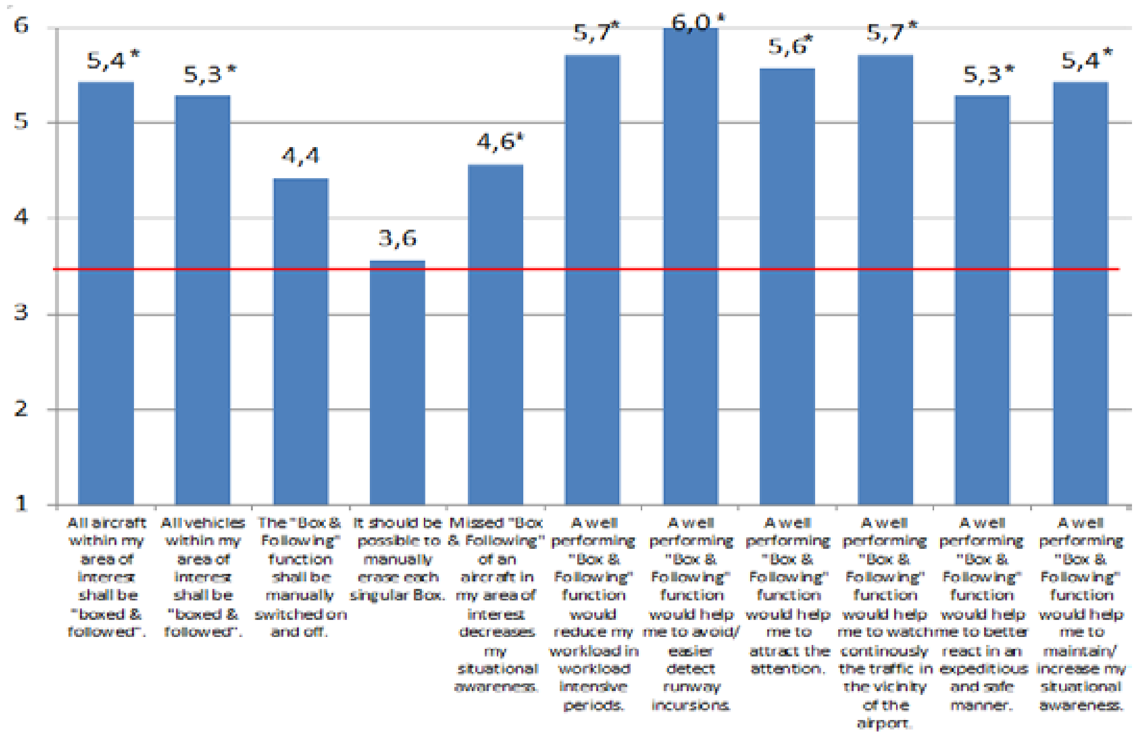

Fig. 5.
Post-trial Questions regarding 11 general Statements to the Automatic Tracking Function
Rem.: An asterisk symbol marks a significant over-average value tested by a binominal test with p = .016.

4. Discussion

The experimental study aimed to get to the bottom of the minimum quality threshold of an automatic tracking function in a remote Tower context. It fixed the relation of "hits" and "missed" with 88% and varied the amount of "unwanted" tracking boxes on three factor levels. Even when the ATCOs recognised performance differences in the amount of "unwanted" tracking boxes and significantly preferred the lower amount of "unwanted" boxes (see Fig. 4), the mid- and post-run standardised measurement tools were not sensitive enough to reveal any significant differences with SA and workload. Instead, a dominant ceiling effect was observed: ATCOs felt permanently confident regarding SA and workload independent of the treatment "amount of unwanted tracking boxes". They appreciated the "wanted" boxes and behaved more or less unaffected from the disturbing "unwanted" boxes.
This result pattern can be explained by three considerations: Firstly, the traffic scenario was challenging but manageable for the ATCOs and in their subjective perception they must have had a proper SA and workload in order to manage such a challenging scenario. This phenomenon is quite well known with ATCO expert samples (Badke-Schaub et al., 2012). That is why the experimental design also focussed on the objective SA measurements, like the SARA-T SA metrics, but unfortunately with the same ceiling effect. Most probably, the SARA-T operational mid-run questions were too easy or not affected by the amount of "unwanted" boxes. Secondly, "What the eye does not see, the heart does not grieve over" is a very good proverb to describe the situation when an aircraft crossed the CTR without a clearance. Even when visible by some pixels in the panorama view, in the BL condition nobody of the seven ATCOs spotted the crosser. The crosser kept unnoticed by them and they did not deal with it, that is, neither workload nor SA was affected, because they did not know that they missed something. By contrast, they detected the crosser through the "wanted" box in the tracking conditions, which surprised them and they were thinking that they have missed an initial call or a clearance. Then they had additional workload by trying to contact the crosser via R/T without any response and to provide traffic information to the traffic in the vicinity to warn of the intruder. All those actions helped to avoid potential safety critical risks but negatively affected ATCOs' subjectively perceived SA and workload. Third consideration why SA and workload remained rather unaffected by the amount of "unwanted" boxes refers to the ATCOs' comments that they could easily distinguish "wanted" from "unwanted" boxes. Particularly large boxes without any contents, stationary boxes or boxes appearing in non-critical areas like on buildings, on the greens or apron could easily been falsified by the ATCOs or even remained unnoticed by them. Critical are "unwanted" boxes with a similar appearance like the "wanted" boxes, .e.g., a moving box appearing in the final approach area with size and vector speed similar to a real target. But those "unwanted" boxes could not be created by the simulation facility.
Further comments from ATCOs presume that they used the tracking function like a non-cooperative surface movement radar (SMR). An SMR provides the ATCO with yellow-coloured pixel swarms on a 2D birds view airport surveillance detection (ASDE) equipment display. The radar cannot distinguish between "wanted" or "unwanted" pixel swarms, it simply shows everything that provides a shadow through the radar beam. The ATCOs do not use such an ASDE as a control tool but as an additional means to verify aircraft or vehicle positions seen through the out-of-the-window view

or provided by pilot reports. Over the time, using an ASDE ATCOs become very efficient in distinguishing between operational relevant aircraft/vehicle shadows or "unwanted" shadows induced by light masts, buildings, grass, snow banks, Tarmac reflections or flocks of birds. Having these considerations in mind that a tracking function is not used as a control tool and that many "unwanted" tracking boxes, after a certain adaption time, can easily be falsified by the ATCO and thus are not that much disturbing, one could think about increasing the sensibility of the tracking function to get "hit" rates of up to 95% or 99% on the costs of higher amounts of "unwanted" tracking boxes. This consideration is also supported by item 5 (Fig. 5) by which the ATCOs uniformly state that "missed" tracking boxes may decrease their SA.
Other results refer to the improved recognition of intruders like CTR or runway incursions. With the tracking function intruders are easier to detect and thus the tracking function significantly contributes to safety (see also Fig. 5 item 7, 8 and 9). Referring to the statement whether the entire tracking function or single boxes should be able to switch off manually, ambivalent results were gained Instead agreement was gained referring the statement what is to be tracked: ATCOs want to have tracked all aircraft and vehicles in their area of interest but not on the apron area when the objects are visible anyway (Fig. 5).

5. Conclusions and Outlook

In accordance to existing studies (see Section 1) this experimental study could also show that an automated tracking function in a Remote Tower environment is very much appreciated by the ATCOs and that they significantly admit its positive contribution to situation awareness and safety. Further on, the tracking function seem to be rather robust against "unwanted" tracking boxes and probably more focus could be laid on the increase of the sensibility in terms of getting higher percentage rates with the "wanted" tracking boxes. Furthermore, defining a quantitatively expressed minimum performance value for "unwanted" tracking boxes seems to be very difficult. This study varied "unwanted" tracking boxes in dwell time and location but there are more attributes, such as size of the tracking box, or if they are stationary or moving. Most probably, each implementation of a tracking function must be repeatedly tuned in line to the local operational needs and accepted by the local ATCOs. Future studies should focus on a bigger sample size and more realistic "unwanted" tracking boxes to provide further empirical evidence to these conclusions.

[3] University of Zagreb, Faculty of Transport and Traffic Sciences, Department of Aeronautics, Croatian Aviation Training Centre, Zagreb, Croatia

Abstract: Paper presents methodology of fatigue risk management through assessment methods and tools and applicative mitigation measures. The research has been targeted towards objectification of the crew fatigue on the sample of flight operations and results interpretation of referent indicators measuring. The crew fatigue is measured using Complex Reactionmeter Drenovac (CRD) device, which records the results of tests solved by pilots in various work conditions. The results are converted in several key indicators, and fatigue is derived from obtained indicators' values. The analysis of the obtained results is conducted using the One Way ANOVA (Analysis of Variance) method by software Statistica 10. Furthermore, the safety risk assessment is conducted for obtained results, which shows the level of risk implicated by crew fatigue. As a conclusion, the recommendations are given for fatigue risk mitigation related to concrete research sample.

Keywords: air transport, fatigue, risk assessment, safety management system, fatigue measurement, analysis methods.

1. Introduction

Fatigue affects various cognitive abilities such as alertness, memory, getting around in space, learning, problem solving, decision making, and more. Besides the restrictions expressed in flight time limitations, a very important role in reducing fatigue risk has a Fatigue Risk Management System (FRMS) that presupposes some method for fatigue quantification.

This paper presents a part of the research carried out in the air carrier and is concerned with finding answer to the question: "Does the individual self-assessment of the current "energy status", which is based on a verbal "self-assessment scale of energy level", comply with objective indicators of "mental efficiency status" measured in the chronometric psychological test (CRD 422).

2. Objectification of the Crew Fatigue

Most commonly used methods for objectification of the crew fatigue are:

- Subjective fatigue scales (Samn Perelli fatigue scale, Karolinska Sleepiness Scale);
- Psychomotor vigilance test (PVT);
- Actigraphy;
- Predictive models (biomathematical algorithms usually use applications like SAFE);
- Sleep diaries.

Subjective objectification of fatigue is also commonly found in fatigue reports and fatigue reporting that are used as main data collection tool. Predictive models can be found in modern crew management software applications and they can warn crew planners on fatigue risk (usually warning messages and colour schemes – from green as no risk to red – high fatigue risk). Other objective methods are used in fatigue studies for specific cases when required by airline (e.g. for certain type of flight operation of an airline) (Steiner et al, 2012).

This paper describes study of fatigue objectification using CRD instruments. The analysis of the obtained results is conducted using the methods of Multi-Criteria Decision Making (MCDM) and Analytic Hierarchy Process (AHP).

The research is aimed to find correlation between cognitive, psychomotor and functional mental disorders, measured with electronic tests of the CRD series and workload parameters of flight crew (pilots). Personal assessments on current state of fatigue (subjective scales) were used. The aim of the research is to identify and quantify elements that affect the risk of fatigue.

3. Description of Research, Measuring Equipment and Methodology

For the purpose of a study, an electronic CRD system of standardized chronometric cognitive tests is used. CRD series have been used in various researches and studies since 1969. Instruments, methodology, measuring parameters and other information are well explained and documented in university book (Drenovac, 2009).

Measurements were made with four male pilots of an average age of 42 years (+/- two years), who are professional airline pilots for the last 11 years (standard deviation 4.7 years) and average 6.305 flight hours (standard deviation of 2.532 hours flight) (Steiner et al, 2018).

[1] Corresponding author: ssteiner@fpz.hr

The pilots were familiar with the method (process and dynamics of the study) and the metering CRD equipment and tests to be used. Firstly, pilots had training for 10 iterations and in single iteration they did five CRD tests on four different CRD instruments (Steiner et al, 2018).
Those testing aimed to prevent the effect of learning how to better do tests in a later measurement because the main objective was to measure the drop of mental potential due to fatigue (Steiner et al, 2018).
Measurements, during which pilots did full tests (five different CRD tests) and fill subjective survey, were done before flight duty period and after flight duty period. Tests were done in improvised "CRD laboratory", a room on International Airport Zagreb, where pilots had done check-in and check-out (pre-flight and post-flight duty).

Fig. 1.
CRD laboratory
Source: Prepared by authors

The subject of measurement of the CRD 422 test is an operational thinking with tasks of work coordination, i.e. hand and leg work combinations depending on the emitted sound level or the sound intensity level.
The signal-command system of the CRD 422 includes, along with the main signal-command board, the connecting elements: headphones (speakers) and pedals. In different tasks, one of two predetermined (high or low) signals is emitted. At high volume, at the same time, it is necessary to press with the left hand, the large key in the left corner of the control panel and, at the same time, press the right foot, the right foot pedal. After hearing low sound, it is required to respond at the same time by pressing the right hand of the large key in the right-hand corner of the control panel and the left foot of the left foot pedal (Steiner et al, 2018). The reason for choosing this test for study presentation is the complexity of co-ordination of hand and foot work, and complex mental processing - operational thinking.
A set of variables obtained by chronometric measurement on the CRD 422 test, which have been analysed in this study are:

- UKT - mental processing speed (total test time);
- MinT - mental processing speed (the shortest time to solve the test tasks);
- MaxT - mental processing speed (the longest time to solve the test tasks);
- UB - total ballast, an indicator of individual stability as a dynamic attribute of mental processing;
- SB - initial ballast (fluctuation of task solving time in the first half of the test);
- ZB - final ballast (fluctuation of task solving time in the second half of the test);
- ZB/SB - the ratio of the final and the initial ballast, greater than 1 means a slowdown in the test solving time, i.e. fatigue;
- BrPog - the number of errors made on the test, the indicator of attention and concentration while solving the tests.

UKT, MinT, MaxT, UB, SB and ZB are time indicators (milli-seconds), and BrPog is an integer that indicates the number of errors. All chronometric data are transposed into the standard statistical scale (T value).
Since chronometric data are distributed asymmetrically, normalization of their distribution is necessary in order to apply statistical methods that assume normal distribution in the analytics. The second reason for the transposition of the original results in milli-seconds into the standard statistical scale (T-value) is to eliminate the individual differences between the pilots and the different sizes of the metric values.
The T-value transposition is made in such a way that the individual results of each pilot on the test are first converted to the standard z value according to the formula z score = (original value – average of the original value) / (standard deviation of the original value). Then z values are transposed into T values by the formula T score = 50 + 10 * z.

The reason for using the T value is that z values also have negative values, which is a drawback for graphic analysis of results (graphs), while T values usually range in the range of 20 to 80, where value 50 denotes the arithmetic mean. By transposing into the standard statistical scale in T values, the same average for each pilot is reached and is 50 in T values, eliminating individual differences.

After the original values in milli-seconds for the UKT, MinT, MaxT, UB, SB and ZB variables were transposed into the standard T value, a further statistical processing was started. It should therefore be taken into account that the shorter time of outlined variables means greater efficiency of mental processing and vice versa, which means that the lower T value of the result represents greater efficiency of mental processing and vice versa.

The dependent variables of BrPog and ZB/SB are further expressed in the original values, where a smaller number of errors indicate higher accuracy of mental processing, and the ratio ZB/SB indicates acceleration or deceleration in mental processing when solving the test - if ZB is greater than SB then it means slowing down, if ratio is greater than 1.

An independent variable represents a subjective result of „self-assessment scale of energy level". Subjective self-assessment scale of energy level contains ranking from 1 to 10, shown in Table 1, where the status rating is the worst for 1 and states: „I'm completely exhausted, unable to do the least effort“, while the status rating of 10 is the best and states: „I feel great energy for which there are no imperceptible obstacles“.

Table 1

Self-assessment scale of energy status

Rate	Description of energy status
1	I am completely exhausted; unable to do the least effort.
2	I'm terribly tired; incapable of any activity.
3	I am very tired; without energy; immobile.
4	I'm pretty tired; apathetic; wishing a good night sleep.
5	I do not have enough energy; I get tired easily.
6	I feel quite fresh.
7	I'm fresh and I have a lot of energy.
8	I have a lot of energy; I feel the need for action.
9	I have great energy and a strong need for action
10	I feel great energy for which there are no imperceptible obstacles.

Source: (Drenovac, 2011)

4. Results

There were altogether 227 reviews of self-assessments of energy level status, ranging from status 5, which states: „I do not have enough energy; I get tired easily“ up to status 8 that states: „I have a lot of energy; I feel the need for action“. The response rate of self-assessment of energy level is shown in Table 2.

Table 2

Response frequency of energy level self-assessment

Self-assessment	Description	N
5	I do not have enough energy; I get tired easily.	30
6	I feel quite fresh.	98
7	I'm fresh and I have a lot of energy.	74
8	I have a lot of energy; I feel the need for action.	25
	Total	**227**

Source: Prepared by authors

In the statistical analysis, the ANOVA procedures of Statistics 10 were used to test the significance of differences in CRD variables between the variables of independent variables, i.e. the self-assessment of energy level. The results of that analysis are shown in the Table 3 and in the graphs 1 and 2.

Table 3

One-way ANOVA variance analysis – Differences in "mental processing efficiency" on CRD 422 among self-assessment categories of „current energy status“

Energy rate	Category 5	Category 6	Category 7	Category 8	F	p
UKT 422 average	55.208	50.866	47.677	46.951	5,317357	0,001476 **
MinT 422 average	51.383	50.305	49.562	48.057	0,576179	0,631230
MaxT 422 average	55.079	49.750	48.601	48.834	3,266034	0,022186 *
UB 422	56.142	50.767	47.387	47.364	6,633782	0,000260 **

Energy rate average	Category 5	Category 6	Category 7	Category 8	F	p
SB 422 average	53.988	50.734	48.038	48.208	3,036948	0,029969 *
ZB 422 average	56.686	50.545	47.434	47.389	7,257021	0,000115 **
BrPog 422 average	1.6667	1.8776	2.7568	4.1600	4,684491	0,003408 **
ZB/SB 422 average	1,482319	1,353771	1,354691	1,492949	1,101157	0,349516

Source: Prepared by authors, Statistica 10
** statistical significance at the level 0,05*
*** statistical significance at the promile level*

The variance analysis showed statistically significant differences in mental efficiency at the risk level less than 0.05 for MaxT and SB variables, and at the risk level in promiles for the variables UKT, UB, ZB and BrPog. In all these variables, except for BrPog, statistically significant weaker mental efficiency was shown in the Category 5 of self-assessment of energy level, in comparison with other self-assessment categories. A statistically significant difference was not found in test variables 422: MinT and ZB/SB.
Additionally, the post-hoc analysis (Table 4) more precisely shows how undesirable self-assessment of category 5, which states: „I do not have enough energy; I get tired easily“, significantly differentiates the efficiency of mental processing in more favourable categories of self-assessment such as Category 6 which states: „I feel quite fresh“; or Category 7: „I'm fresh and I have a lot of energy“ or Category 8: „I have a lot of energy; I feel the need for action“.

From the Figure 2, it is noted that the mental speed and stability of the mental processing of the pilots (expressed in UKT, MaxT, UB, SB and ZB) is lower than the self-assessment of energy level. However, this is not the case with the attention indicator (number of errors), i.e. the concentration of the pilot was worse as the energy rating was higher (Figure 3).

5. Fatigue Risk Management and Related Safety Risk Assessment

Fatigue Risk Management System (FRMS) is "a data-driven means of continuously monitoring and maintaining fatigue related safety risks, based upon scientific principles and knowledge as well as operational experience that aim to ensure relevant personnel are performing at adequate levels of alertness" (IATA; ICAO; IFALPA, 2015).
Information and reports' data related to crew alertness are routinely collected and analysed by the means of an effective FRMS. FRMS helps to control the risk associated with fatigue. FRMS can be established as a standalone system or as a part of the Safety Management System (SMS).
FRMS aims to ensure that flight crew members and cabin crew are sufficiently careful to work at a satisfactory level of performance. The principles and processes from the Safety Management System (SMS) are applied to manage the specific risks associated with the crew member's fatigue. Like SMS, FRMS seeks to achieve a realistic balance between safety, productivity and costs (IATA; ICAO; IFALPA, 2015). It seeks to proactively identify opportunities to improve operational processes and reduce risk, as well as to recognize disadvantages after adverse events. The structure of the FRMS is modelled on the SMS basic framework. Basic activities are Safety Risk Management and Safety Assurance. These basic activities are governed by FRMS policy and supported by FRMS promotion processes.
SMS and FRMS rely on the concept of an effective reporting culture, where staff are trained and are constantly encouraged to report any dangers (hazards) whenever recognized at the work environment (Steiner et al, 2012).
The FRMS's goals are to "manage, monitor and mitigate the effects of fatigue to improve flight crew members' alertness and reduce performance errors" as well as to balance safety and productivity (Starr, 2017).
The use of SMS to manage fatigue is fundamental. Fatigue is recognized as aviation hazard and as such, it creates risks, for which is essential to maintain the solid SMS. Because of this, basic SMS elements should be established (Steiner et al, 2018).
Incorporation of an FRMS works in parallel with the elements of the Safety Risk Management component of the organization's SMS. Further, the FRMS supports the Safety Assurance component of SMS by providing, among other things, performance monitoring and a system of employees' reporting. Finally, Safety Promotion component of SMS, needs to establish safety as a core value with a sustained Safety Culture (Starr, 2017).

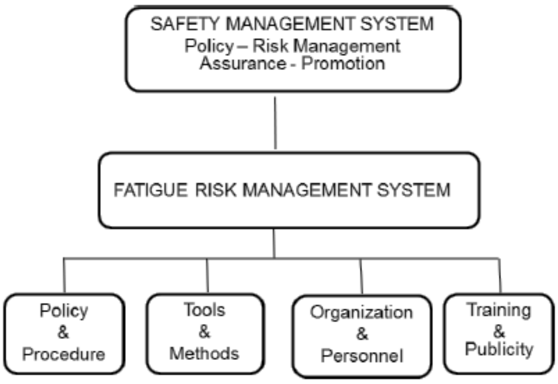

Fig. 4.
SMS and FRMS
Source: (Starr, 2017)

Safety Risk Management (SRM) is used to identify hazards, analyse identified hazards, conduct the safety risk assessment using the ICAO Doc 9859 tools (safety risk matrix), and to propose the risk mitigation measures in order to reduce, mitigate or eliminate risk.
The objective of safety risk management is to assess the risks associated with identified hazards and develop and implement effective and appropriate mitigations. Safety risk management is therefore a key component of the safety management process.
Fatigue is identified hazard to safety of air transport operations. Due to this fact, Fatigue Hazard is analysed and recognized as potential danger to safety of air operations.
Next step of SRM is Safety Risk Assessment. In order to obtain the risk level, it is necessary to evaluate Risk Probability (Table 5), i.e. how often does the fatigue occur; and it is necessary to evaluate Risk Severity (Table 6), i.e. what could be severity of such fatigue risk occurrence.

Table 5
Risk probability of the fatigue hazard

Likelihood	**Meaning**	**Value**
Frequent	Likely to occur many times (has occurred frequently)	5
Occasional	Likely to occur sometimes (has occurred infrequently)	4
Remote	Unlikely to occur, but possible (has occurred rarely)	3
Improbable	Very unlikely to occur (not known to have occurred)	2
Extremely improbable	Almost inconceivable that the event will occur	1

Source: ICAO, 2018

Table 6
Risk severity of the fatigue hazard

Severity	**Meaning**	**Value**
Catastrophic	▪ Equipment destroyed ▪ Multiple deaths	A
Hazardous	▪ A large reduction in safety margins, physical distress or a workload such that the operators cannot be relied upon to perform their tasks accurately or completely ▪ Serious injury ▪ Major equipment damage	B
Major	▪ A significant reduction in safety margins, a reduction in the ability of the operators to cope with adverse operating conditions as a result of increase in workload, or as a result of conditions impairing their efficiency ▪ Serious incident ▪ Injury to persons	C
Minor	▪ Nuisance ▪ Operating limitations ▪ Use of emergency procedures ▪ Minor incident	D
Negligible	▪ Little consequences	E

Source: ICAO, 2018

Once the Risk Probability and Risk Severity are defined, the Risk Level is obtained from the Safety Risk Assessment Matrix (Table 7), and by obtaining the Risk Level, the Tolerability (Acceptability) Area of the risk can be determined.

Table 7
Risk severity of the fatigue hazard

Risk probability		**Risk severity**				
		Catastrophic **A**	Hazardous **B**	Major **C**	Minor **D**	Negligible **E**
Frequent	**5**	**5A**	**5B**	**5C**	**5B**	**5A**
Occasional	**4**	**4A**	**4B**	**4C**	**4D**	**4E**
Remote	**3**	**3A**	**3B**	**3C**	**3D**	**3E**
Improbable	**2**	**2A**	**2B**	**2C**	**2D**	**2E**
Extremely improbable	**1**	**1A**	**1B**	**1C**	**1D**	**1E**

Source: ICAO, 2018

The margins of fatigue risk belong to the Tolerable Area, and appropriate actions need to be conducted accordingly, as described in Figure 5.

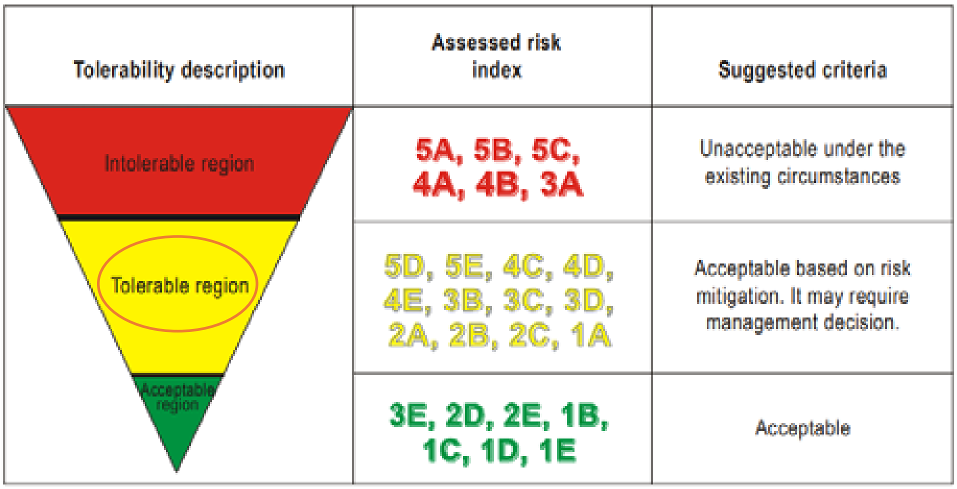

Fig. 5.
Tolerability of the Risks
Source: ICAO, 2018

Considering what the Fatigue Hazard represents, it is mandatory to ensure Risk Mitigation measures in order to reduce risk level to the acceptable. Therefore, further research, to explore and define appropriate mitigation measures to reduce fatigue risk levels to the acceptable, should be conducted.

6. Conclusion

According to the results presented in this study, it can be argued that the objective indicators of mental efficacy determined by chronometric testing on the CRD 422 test agree with the individual self-assessment determined on the verbal "self-assessment scale of energy level". That is indicated by the significance of the differences (ANOVA analysis procedures) at the risk level less than 0.05%, or at the risk level in promiles.
The exception was the BrPog variable, which is the indicator of attention when solving tasks in the CRD 422 test for which a statistically significant difference in risk level was observed, but the (paradoxically) concentration of attention was lower as self-assessment was more favourable. This finding needs to be furtherly explored.
Fatigue affects various cognitive abilities such as alertness, memory, getting around in space, learning, problem solving, decision making, and more. Fatigue Risk Management System (FRMS) and Safety Management System (SMS) have very important role in reducing fatigue risks and should be used as a tool to determine and manage fatigue hazards.

MODEL OF THE OPERATION PROCESS OF AIRCRAFT IN THE TRANSPORT SYSTEM

Anna Borucka[1]
[1] Military University of Technology, Faculty of Logistics, Poland

Abstract: Correct operation of technical facilities ensures uninterrupted performance of tasks. Therefore, reliable description of operation process is an important issue that enables proper control of its processes, as well as to ensure and maintain required operation level. In this case, appropriate mathematical methods and tools are applied, which provide important knowledge, not only to persons responsible for carrying out orders, but also to the logistical component responsible for securing them. In many situations, the processes of mathematical analysis of the operation process are hampered by traditional method of processing and recording documentation. Modern systems that enable to obtain accurate and multidimensional information on the activities carried out by technical facilities are implemented in companies gradually, sometimes even not at all. Although such traditional records seem to be an obstacle to use forecasting mathematical tools, this article presents a mathematical description of aircraft operations based on such information. ARIMA model was proposed, which allowed not only for short-term forecasting of future flights, but also for current evaluation of operations, possibility to control and coordinate flight schedules, especially in terms of maintenance and repairs. Such information enabled to improve implementation process of performed tasks, including sustainable use of human and technical resources.

Keywords: forecasting, aircraft, ARIMA model, transport means.

1. Introduction

The world of science and technology, among many different areas, also focuses on development and improvement of the theory and practice of creating, exploiting and eliminating of technical objects, thus creating three basic branches of knowledge dealing with the science and technology of technical objects exploitation, presented in Fig. 1 (Będkowski and Dąbrowski, 2000).

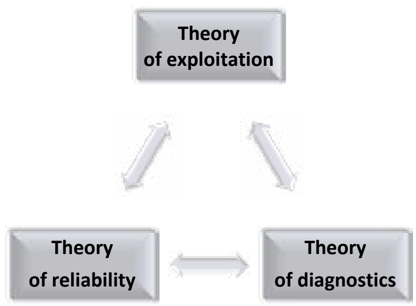

Fig. 1.
Pillars of science on exploitation
Source: Adapted from (Będkowski and Dąbrowski, 2000)

An aim of the exploitation theory is to define such conditions of using technical objects, which will ensure their highest efficiency in the safest and least cost way (theory of use) and will allow to maintain, and if necessary to restore the lost properties during operation (theory of operation) as optimally as possible. However, the theory of reliability refers to period of designing and manufacturing technical objects by defining the principles of creating constructional and functional structures, as well as operating procedures ensuring their best performance. The theory of diagnostics, in turn, concerns the process of controlling exploitation of technical objects. Therefore, it requires knowledge of their condition and deals with identifying the most accurate, cheapest and safest way to obtain information on the technical condition of objects (Będkowski and Dąbrowski, 2000). Methods of diagnostic tests enable to recognize the object state on the basis of available observation results of its operation and the existing interactions between object and its surroundings. On this basis, maintenance and repair intervals are defined. Timetables for restoration works of the object must take into account the uninterrupted performance of necessary tasks (Woropay, 1996) to ensure that there are no delays and that the remaining objects are operational.

Knowledge concerning diagnostics of the condition of possessed technical objects is particularly important in systems requiring sudden, unexpected interventions. Such a system is, for example, the armed forces, and in particular their air component. Ensuring the safety of flights is the most important issue, and therefore it is necessary to respect the established maintenance intervals throughout the entire service life. Furthermore, these processes require a certain amount of time and their implementation excludes the aircraft from operation. This may affect the readiness of the entire base and efficiency of assigned tasks. That is why it is so important to take into account, in the process of command, all the factors that may interfere with proper functioning of the base. Nevertheless, the specific nature of

[1] Corresponding author: anna.borucka@wat.edu.pl

armed forces means that most of taken decisions are based on the knowledge and experience of commanders, as well as on laws and regulations governing the operation of the army. Existing modern technologies on the civil market for identification, collection and representation of data, which may be a support in the management of the fleet, are being introduced gradually in the army. Difficulty of their implementation results mainly from the size of the army, which is formed by many military units, differing in location, tasks, equipment, and the level of computerization. Moreover, there is still functioning traditional (non-digital) way of document flow and archiving, which makes it difficult to use not only the latest technological achievements, but also mathematical methods and tools based on the data obtained from this system. Standardization and digitization of such a system requires huge financial expenses and a long period of implementation. At the same time, priority projects must also be carried out, related to preparing soldiers to conduct combat activities, which requires not only permanent training, but also modernization of possessed resources, improvement of their condition or exchange for new ones. However, products and services used in civil activities that enable to identify, locate and monitor transport means would be for commanders not only support of everyday operations, and guarantee more efficient and effective resource management, but would also provide reliable data and forecasts on their basis. So far, both due to the specificity of the army and mentioned traditional method of documentation processing, the use of mathematical forecasting tools in the army has been negligible. However, the present study attempts to predict the activities carried out by aircraft on the basis of currently possible to obtain available data. Based on empirical data from two years of operation, a method for describing aircraft operating states based on the ARIMA model has been proposed and is presented in the article. It enables to assess the readiness of military facilities and ultimately to analyze the areas, in which they can be improved.

2. Introduction to ARIMA Model

The evolution in time of any object with properties described mathematically by a set of one-dimensional random variables $X(t)$ with values $x(t)$ randomly dependent on physical (continuous) or discrete (e.g. calendar) time t is called the time series. Otherwise, it is a sequence of information in chronological order. Analysis of time series enables to determine the nature of studied phenomenon, to find (if any) deterministic element and to present the analyzed process as a function of random and deterministic elements. This enables to forecast future values of time series (Bielińska, 2007).

Among the models used to describe real stochastic processes, the ARMA stationary series (Autoregressive Moving Average Model) and ARIMA non-stationary series (Autoregressive Integrated Moving Average Model) take a special position. These are models based on the autocorrelation phenomenon, developed by integration of the autoregressive model (AR) and moving average model (MA) (Bielińska, 2007; Czyżycki, Klóska, 2011).

The ARMA model assumes that the value of forecasted variable at time *t* depends on its past values and on differences between its past real values and the values obtained from the model – forecast errors. The form of ARMA model is as follows (1) (Dittmann, Szabela-Pasierbińska, Dittmann, Szpulak, 2011; Sokołowski, 2016):

$$y_t = \alpha_0 + \alpha_1\, y_{t-1} + \alpha_2\, y_{t-2} + \ldots + \alpha_p\, y_{t-p} + \varepsilon_t\, \beta_0 + \varepsilon_t - \beta_1\, \varepsilon_{t-1} - -\beta_2\, y_{t-2} - \ldots - \beta_q \varepsilon_{t-q} \quad (1)$$

Determination of the ARMA model is used to determine three parameters: autoregressive parameter (p), differential order (d) and moving average parameter (q). Since the classic ARMA models can only be used for stationary series, it is necessary to analyze this state. The most common cause of non-stationary is the existence of a trend or seasonal variations, which can be eliminated by applying logarithmic or differential transformations, thereby leading the series into stationary. Then we are talking about the ARIMA model. The use of a letter *i* means that the studied time series has been differentiated. Non-stationary caused by seasonal variations is eliminated by seasonal differentiation. This is the SARIMA model (Seasonal ARIMA), which allows for modelling of seasonal data. It is constructed by supplementing the ARIMA model with element resulting from the seasonality of analyzed process, taking into account P – seasonal delays row of AR type, Q – seasonal delays row of MA type, D – seasonal differentiation component

3. Characteristics of the Research Object

In the process of operating an aircraft, it is essential to plan the operations process in such undisturbed way so that orders could be executed smoothly, flight safety could be ensured and the maintenance process could be properly scheduled. Therefore, commanders should be provided with reliable information concerning planned flights in order to ensure the continuity of tasks and proper use of resources. The possibility of forecasting may ensure excellent support for military scenarios.

The study was carried out on flights by military aircraft. The documentation was available, which is a reflection of the exploitation year, and on its basis the possible technical conditions were identified, in which the analyzed objects are located. The article presents analysis of the exploitation state – performance of task, which is the flight. Collected data was divided into three groups, due to great variability, which precludes the estimation of reliable forecasts. In this way was created:

- short flights, lasting up to 30 minutes, these were flights characterized by the highest frequency,
- average flights, lasting from 30 and 60 minutes, also with a high intensity level,

- long flights – above an hours, which intensity was lower in comparison to short and average flights.

Results of study for a group of short flights are presented in the following section. The first step was a visual inspection of studied series, presented in Fig. 2. Individual observations are noticeable, definitely distant from others, which suggest that these are untypical observations. This is confirmed by the box plot in Fig. 3.

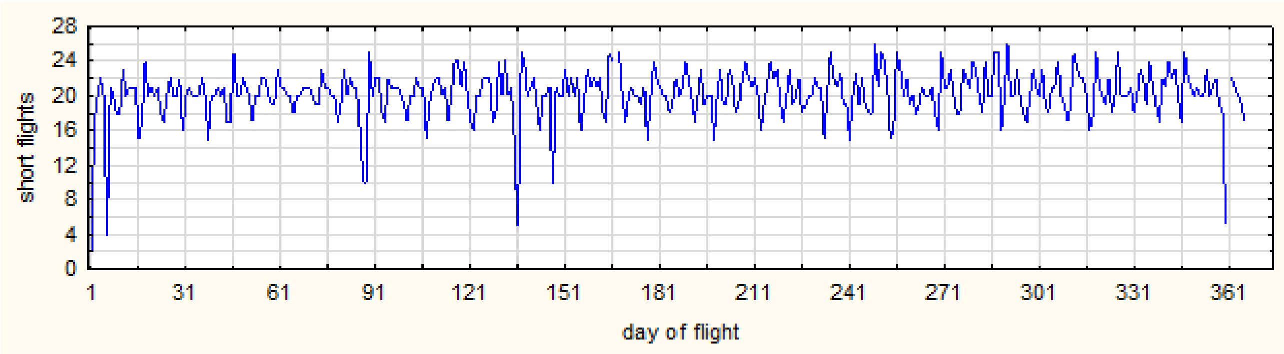

Fig. 2.
Diagram of studied time series
Source: own study

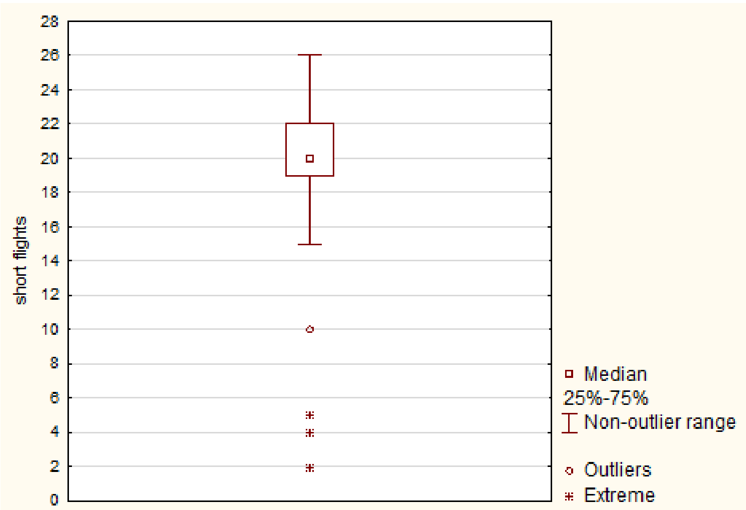

Fig. 3.
Box plot of studied series
Source: own study

A detailed analysis of disturbing observations showed that they concern national and church holidays, when the activity of base and the number of performed tasks is negligible. In the scale of the whole process, there were 6 observations on: 1.01 (the New Year), 6.01 (Epiphany), 27-28.03 (Easter), 15.05 (Pentecost), and lack of observations on the following dates: 15.06 (Corpus Christi) and 25-26.12 (Christmas Day). It was decided that these observations would be unusual and would be replaced with a median, which would result in the following process (Fig. 4):

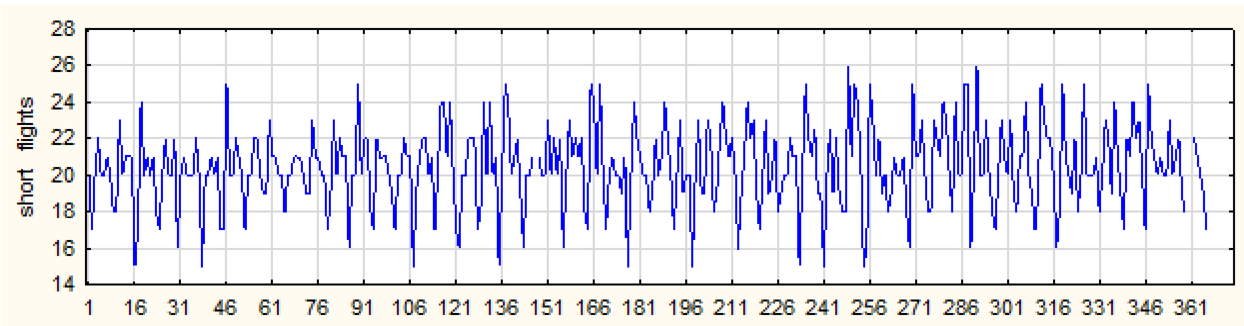

Fig. 4.
Diagram of transformed time series
Source: own study

Analysis of empirical distributions of the duration of analyzed exploitation state is necessary not only to correct doubtful observations, but also to avoid analytical uselessness of the model, which may be caused by e.g. multimodality of distributions.

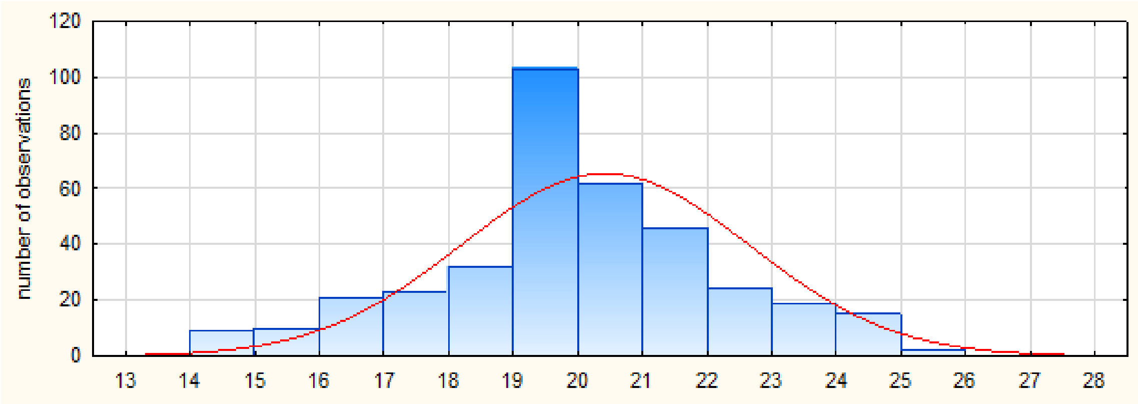

Fig. 5.
Histogram of studied series
Source: own study

The distribution is not normal, but fulfils the criterion of mono-modality (Fig. 5). Moreover, it does not show a noticeable upward or downward trend (Fig. 4) and therefore there is no basis for assuming the existence of a trend. However, a certain seasonality of the process is noticeable on enlarged diagram (Fig. 6).

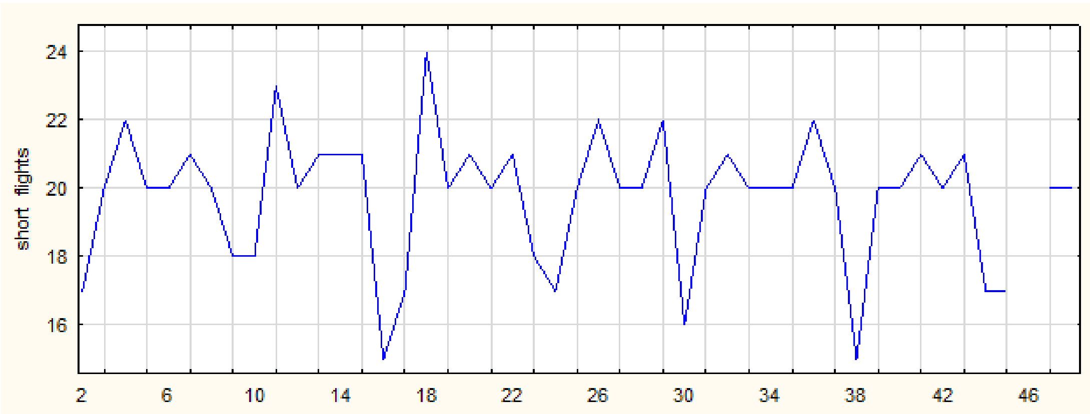

Fig. 6.
Approximate diagram of time series
Source: own study

It turns out that the intensity of performed tasks is much lower on Saturdays and Sundays in comparison to remaining weekdays, while the majority of tasks are performed on Mondays, as confirmed by the categorized box plot (Fig. 7).

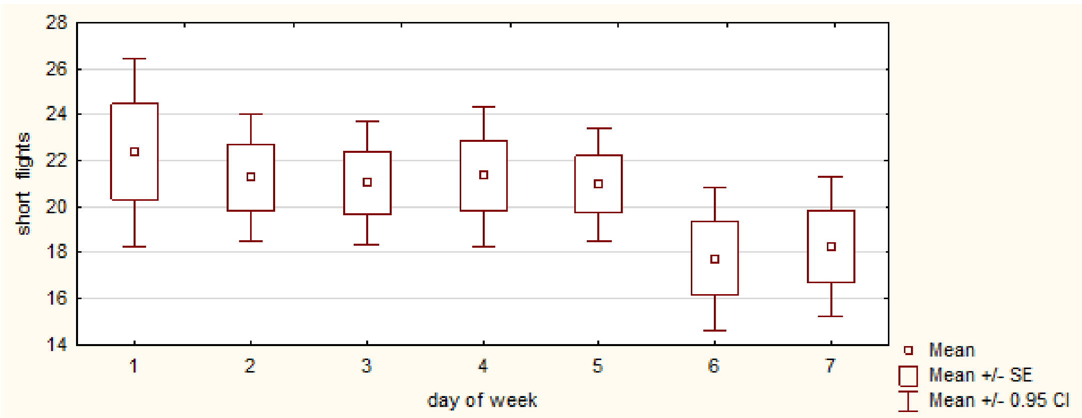

Fig. 7.
Box plot of studied series according to weekdays
Source: own study

The seasonality of process causes that the studied series is not stationary, and due to the fact that ARIMA methods can only be applied to stationary series or led to stationary series, it is necessary to achieve at least stationary in a wider sense (invariability during the first and second moment) (Dittmann, *et al.,* 2011; Sokołowski, 2016). The autocorrelation function ACF (Fig. 8) and partial autocorrelation function PACF (Fig. 9) is helpful in the assessment of stationarity, as well as in model construction.

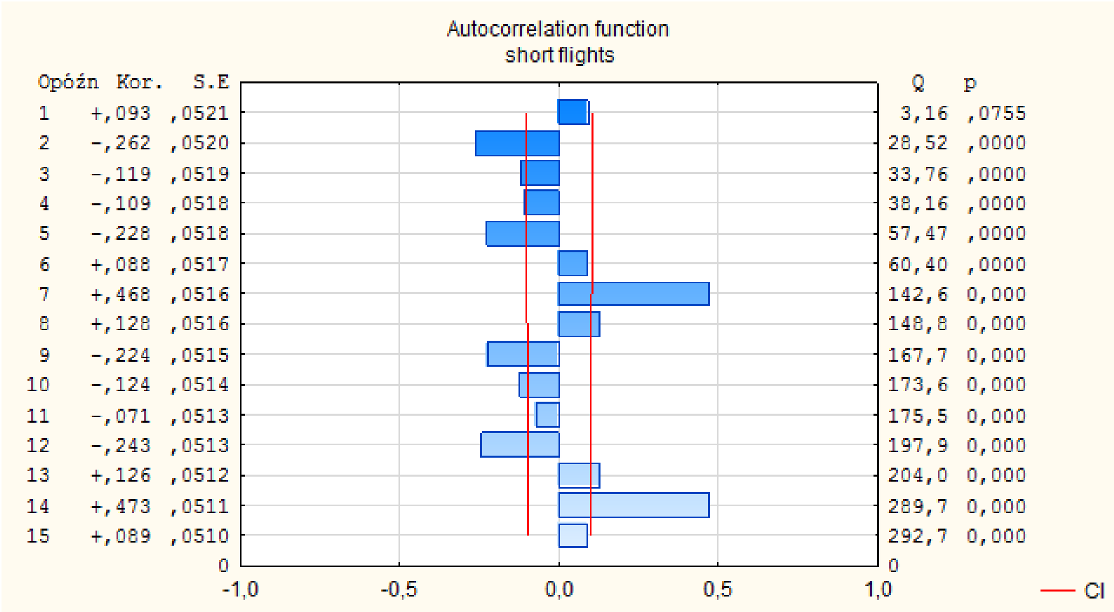

Fig. 8.
Autocorrelation function diagram of studied series
Source: own study

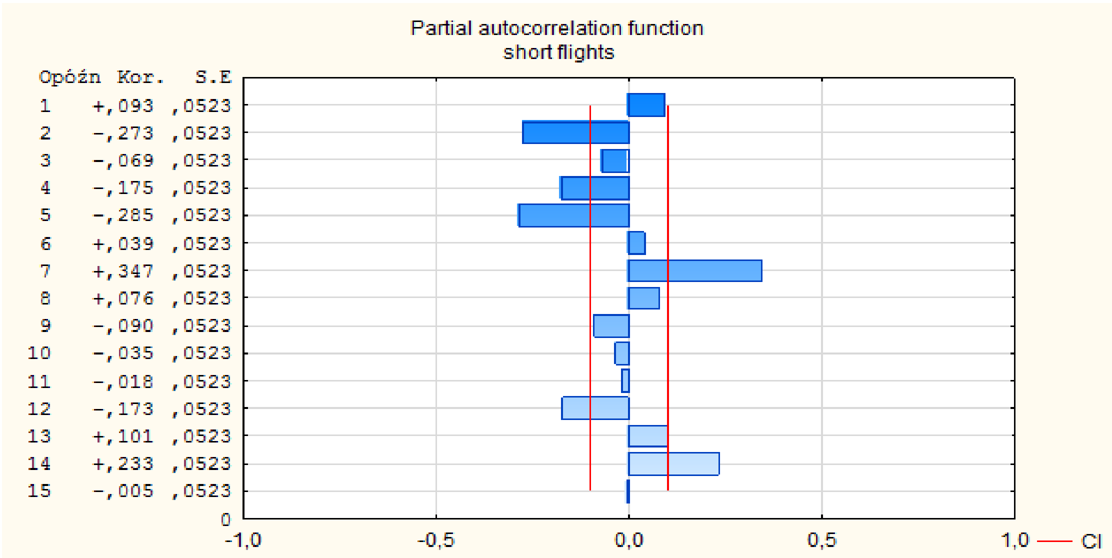

Fig. 9.
Partial autocorrelation function diagram of studied series
Source: own study

Diagram of partial autocorrelation function PACF suggests that it should not be the autocorrelation process. However, the autocorrelation function ACF decreases for most of delays, taking a form of fading sinusoid, which confirms that the process is not stationary (Bielińska, 2007). In the first place, the non-seasonal differentiation was conducted and the autocorrelation function was re-studied (Fig. 10).

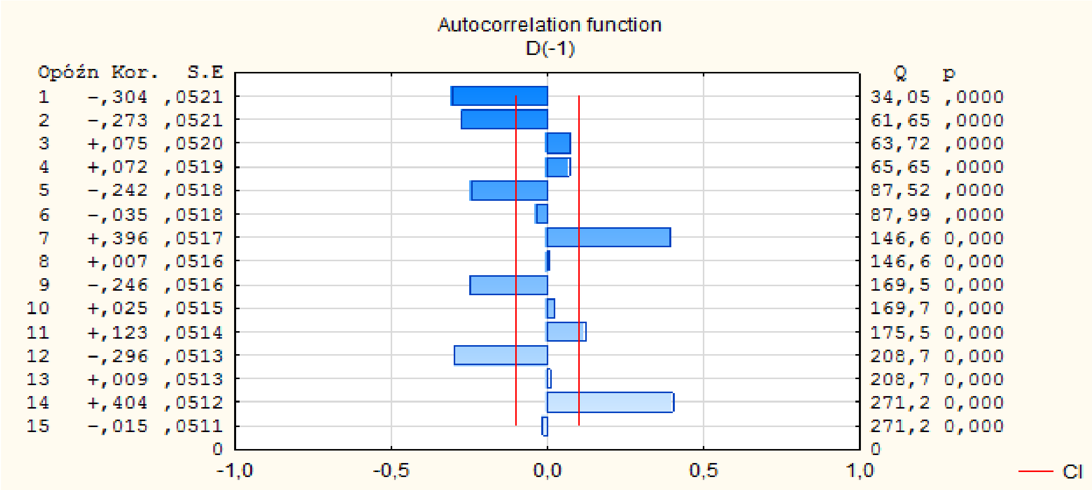

Fig. 10.
Diagram of autocorrelation function with non-seasonal delay d=1
Source: own study

Most of significant values of the autocorrelation function disappeared, but there also remained significant values for the first two delays. There is also a clear correlation for delay 7 and its multiplication, which suggests the need to carry out the process of seasonal differentiation with a delay equal to 7. Finally, it was decided to estimate the ARIMA model with the testing down method, assuming initially that it is a moving average process with the parameter $q = 2$. To stabilize the variance, the series was also logarithmed. In order to take into account seasonal variations resulting from lower intensity of flights, on weekend days the series were subject to seasonal variation with a delay of 7 and the seasonal moving average Q was estimated. Due to an ambiguous course of autocorrelation function, the model with autoregressive parameter was also tested. Selected estimation results are presented in Table 1 (statistically significant parameters are underlined). To estimate the models, a time series shorter by the last five observations was used, which was retained as a test series for the analysis of forecast.

Table 1
Summary of estimation results

		SARIMA model (1.1.2)(0.0.1)	SARIMA model (0.1.2)(0.1.1)	SARIMA model (0.1.2)(0.1.1)	SARIMA model (0.1.2)(0.0.1)	ARIMA model (1.1.1)(0.1.0)

Source: own study

The evaluation of proposed models first comes down to checking whether the estimated parameters are statistically significantly different from zero, as the insignificant parameter informs that the variable does not affect fitting the model and can be omitted from it. In listed models only in SARIMA model (0.1.2)(0.0.1) and ARIMA (0.1.2)(0.0.1) model, one parameter is statistically insignificant. Therefore, it was necessary to use different measures. These can be different information criteria or the value of mean error MS, but it is particularly important to diagnose the distribution of residuals, which in a properly constructed model should be characterized by randomness and symmetry. Therefore the stationary and normality of their distribution should be investigated. Again, the autocorrelation functions and partial autocorrelation functions were used for this purpose. It turned out that only for SARIMA (0.1.2)(0.1.1) model the correlograms met the above assumptions. The diagrams of ACF and PACF functions presented below (Fig. 11 and Fig. 12) show the lack of statistically significant autocorrelations and partial autocorrelations, whereas the normality graph (Fig. 13) does not differ significantly from normal distribution and enables to consider the model residues as a white noise process.

Positive verification of the model enabled to determine the forecast (Fig. 14) and assess it on the basis of known observations, which were retained as test observations that along with a relative error in the forecast were presented in Table 2.

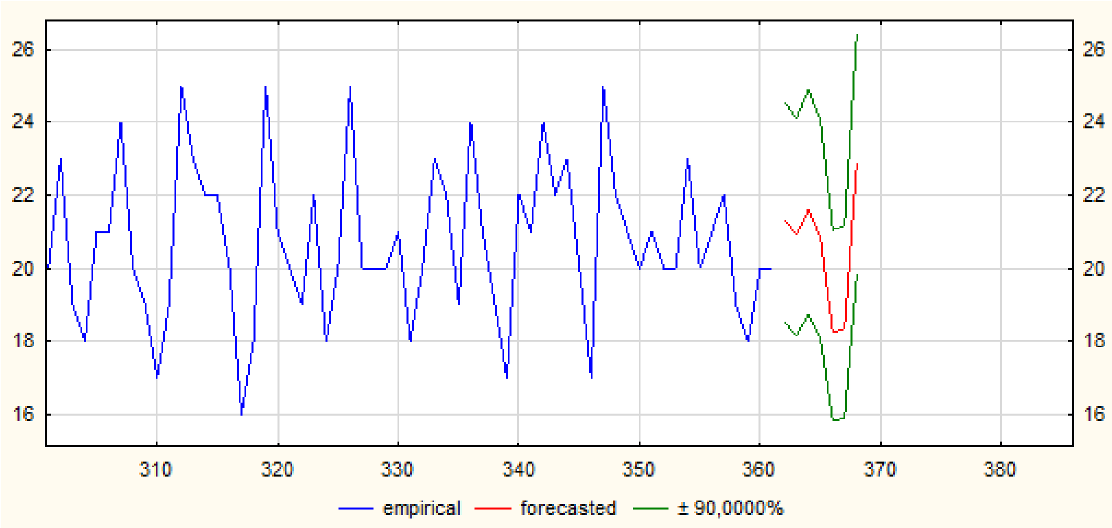

Fig. 14.
Diagram of studied series and forecasts

Table 2
Verification of obtained forecast

Date	Number of observations	Forecast	Empirical data	Mean standard error Ψ [%]
2017-12-27	367	18,27851	21	-1,5932
2017-12-28	368	22,75831	21	0,3604
2017-12-29	369	21,03319	22	1,80208
2017-12-30	370	21,00812	21	0,70824
2017-12-31	371	21,37311	17	-7,3903
2018-01-01	372	20,94401		
2018-01-02	373	17,88985		
2018-01-03	374	18,40636		
2018-01-04	375	22,57938		
2018-01-05	376	21,18032		

Source: own study

The obtained results of forecasting errors are small, which is particularly satisfactory as the test observations concerned the end of the year, which could cause significant errors. The biggest forecasting error concerns 31.12.2017, but it is New Year’s Eve, a day preceding the day off, i.e. the New Year. Therefore, the exploitation intensity was lower, which caused the forecast to be overestimated. An approximate diagram of analyzed time series, taking into account test observations and forecasts, is presented in Fig. 15.

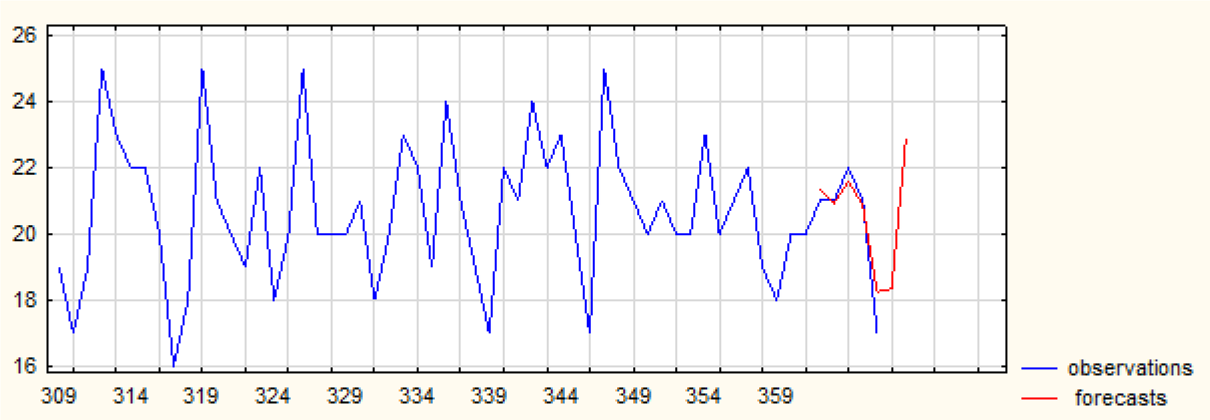

Fig. 15.
Approximate diagram of studied series and forecasts
Source: own study

Of course, each forecast requires constant monitoring and verification, and its task is only to support management processes, and not to provide ready-made answers. Conducted analysis showed that current methods of data acquisition, processing and archiving – used by the armed forces – allow for creation of reliable models, which can be used in decision-making processes concerning military exploitation systems. The combination of commander's experience and mathematical methods can turn out to be a very effective approach.

3. Conclusions

The article presents an example of practical use of the ARIMA model for forecasting military exploitation systems. Using the time-series analysis, based on the dependence of studied characteristic (variable) from the time, led to conclusions concerning the dynamics of studied phenomenon in the near future. Short-term forecasts are important not only in the process of managing a company, but also in command, in the military environment. They allow for proper delegation of tasks, ensure necessary forces and resources to carry them out, as well as more accurate decisions associated with preparation to carry out potential orders.
Conducted study enabled to predict the demand for flights with a high degree of probability. This allows the commander to plan tasks more precisely for his subordinate staff, to manage his aircraft, and as a result with great credibility to determine the readiness of system, which is managed.

SLOT ALLOCATION PROCESS AS A TOOL FOR OPTIMAL USE OF AIRPORT CAPACITIES

Božo Krilanović[1], Stanislav Pavlin[2], Matija Bračić[3], Arijana Modić[4]
[1] *Dubrovnik Airport, Croatia*
[2,3,4] *University of Zagreb, Faculty of Transport and Traffic Sciences, Croatia*

Abstract: The air traffic system is characterized by insufficient infrastructure capacity, particularly on the congested airports. Slot allocation process is an operational approach that is used to maximize the utilization of available airport infrastructure. The purpose of the aerodrome slots allocation is to optimize airport operations, develop an optimal airlines flight schedule and ensure the introduction of new airlines. The current slots allocation process in the European Union, which is based on the IATA guidelines, is not optimal and requires improvements. In addition is presented the slot allocation method based on the IATA guidelines. The paper presents a slot allocation processes at European Union airports and shows Dubrovnik airport case study.

Keywords: airport capacities, slot allocation, airlines, Dubrovnik airport.

1. Introduction

Due to global air traffic growth and insufficient airport infrastructure development the number of congested airports is increasing. Consequently, there are significant delays at arrivals and departures at airports, resulting in lower service quality and penalties for air carriers. In order to reduce the delays caused by insufficient capacity, airport slots were introduced.
The International Air Transport Association (IATA) in collaboration with air carriers, airports and air traffic industry experts, has developed a set of procedures whose main goal is to provide guidance for the implementation of slot allocation process at the congested airports.
The slots allocation process at airports can performed on the primary and secondary mode. The primary slot allocation at European airports is administrative process defined in the EU Slot Regulation 95/93, based on the global aerodrome slot allocation principles prescribed in the IATA Worldwide Slot Guidelines (IATA, 2017). According to the regulation, the primary allocation applies historical criteria for the use of airport slots held by air carriers present on the market for a longer period. Air carriers entering the market can access only the remaining available capacities. Secondary slots allocation implies the process of exchange and slots trading between air carriers (Zografos et al., 2017).

2. Airport Slot Allocation

Slots are permits for carrying out aircraft operations when traffic demand is higher than the available airport capacity (Kalligiannis, 2010). An air carrier who cannot perform operations within the slot time, or if it does not intend to use it, is obliged to return that slot to the airport for reallocating to other air carriers. Definition of slot use proves that airport slots are not and cannot be the property of air carriers.
Slot allocation is a planning tool to ensure that the available slots are efficiently used at the coordinated airports where infrastructure capacity does not meet air traffic demand. At such airports, a slot coordinator shall be designated to allocate aerodrome slots to air carriers. Also, the purpose of slot allocation is the transparent, non-discriminatory and optimal use of aerodrome capacities as well as the efficient and optimal use of the slots allocating process (Butcher, 2017). Aerodrome slots are allocated twice a year, for the summer and winter season. Today's slots allocation system is based on the historical rights. Historical rights have carriers who fulfilled the condition defined by the *Use it or lose it* rule (IATA, 2017). The current slot allocation system, based on historical rights, does not allow optimal flight schedules for new air carriers.
There are 73 airports in Europe partially or fully coordinated and slot allocations are based on IATA guidelines (De Wit and Burghouwt, 2008).
The slot allocation process in Europe is based on the airport coordinating parameters such as: capacity of the runway, passenger terminal and other infrastructure components. At heavily congested US airports, additional negotiations should be carried out to allow the use of appropriate gate, check-in counters, baggage handling and other important parameters. Aerodrome slots allocation may also relate to other operational or environmental criteria that affect the available capacity.
The airports are categorized, regard to the traffic level they are exposed and airport capacities according to the IATA, into three categories (IATA, 2017):

- Level 1 - non-coordinated airports;
- Level 2 - schedule facilitated airports;
- Level 3 - coordinated airports.

Level 1 airports represent airports where currently available infrastructure meets the traffic demand at all times of the year.

[3] Corresponding author: matija.bracic@fpz.hr

Level 2 airports are those airports where there are potential for traffic congestion at certain time periods. Excessive congestion over a given period may adversely affect the regular operations at the airport.
Level 3 airports are those where service providers have not sufficiently developed airport capacities or where the government has set conditions that preclude the fulfillment of traffic demand. At these airports, the slot coordinator must be appointed to allocate aerodrome slots to air carriers (IATA, 2017).

3. Slot Allocation Rules

The primary criteria for initial slots allocation is based on the historical rights and coordinators should allocate airport slots according to the next priority order (IATA, 2017):

- Operations performed on a regular basis;
- Non- regular („Ad Hoc ") operations;
- Other operations.

When historical slots and changes of historical slots are allocated, the coordinator establishes a slot pool that includes historically allocated, non-allocated and new created aerodrome slots (IATA, 2017). In the initial allocation phase, 50% of the slots in the pool must be allocated to new air carierrs. An exception is the case where the requirements of new air carriers on the market are less than 50% of the total requirements of all carriers at a particular airport (IATA, 2017).
When a slot can not be allocated using the primary allocation criteria, additional factors are considered, such as: time of operation, type of operation and market, competition, the airport working hours, passenger and other user requirements, local guidelines and regulations, frequency of operations etc.

4. Historical Slots and *Use it or lose it* Rule

The principle of slot allocation at the EU airports is based on the slot historical rigths (IATA, 2017). Historical slots are series of slots that have the advantage for the next equivalent flight season. "Historic precedence applies to a series of slots that was operated at least 80% of the time during the period allocated in the previous equivalent season" (IATA, 2017). Coordinators are obliged to inform the carriers in advance if there is a risk that this condition will not be fulfilled. This criterion is called the *Use it or lose it* rule. If the condition of 80% of the slot allocation is not met, the slots will be returned to the slot pool after the end of the allocation period.

4.1. Justified Non-utilization of Slots

Slots which are not used will be considered as realised if the non-utilization is justified for any of the following reasons (IATA, 2017):

- Interruption of air traffic services because *force majeur* (closing an airport or part of the airspace because of the bad weather conditions…);
- Actions taken to harm and sabotage the normal provision of air carrier services such as strikes.

4.2. Intentional Misuse of Slots

At the level 3 airport slots must be allocated to each carrier before starting operations. The following actions are considered to be misusing slots (IATA, 2017):

- keeping allocated slots for which, the carrier has no intent to use, transfer, exchange or use for shared operations ("Slot Babysitting");
- keeping allocated slots to reduce airport capacity for a certain period to other carriers;
- requiring new slot allocation that the carrier does not intend to use;
- requiring slot allocation with the aim of gaining greater priority for future slots.

5. Slot Allocation Process at the Dubrovnik Airport

Dubrovnik Airport (DA) is an international airport. According to the passenger traffic data is the third Croatian airport with 2.3 million passengers in 2017 (Dubrovnik Airport, 2018). Based on the IATA methodology, the DA is categorized as level 2 airport. According to the IATA guidelines, the DA is obliged to use the term "Authorized Time" instead of the term „Slot"(in further text is mainly used term slot).
The available airport capacities are particularly congested in June, July, August and September with approximately 400,000 passengers in 2017. Daily peak periods were on Thursdays, Saturdays and Sundays with approximately 21,000 passengers (Dubrovnik Airport, 2018). During the summer season 95% of the annual traffic is realised, and in the winter season remaining 5%. The busiest month in 2017 at the DA was July with 442,122 passengers while the minimum passengers were handled in January, 19,329 (ratio about 23:1).
The number of aircraft operations also shows a large degree of inequality: in the busiest month, August, 3,524 operations, and at least busy month in January, 264 operations (ratio about 13.5:1).

The number of operations on the DA on an annual basis for the period 2010-2017 is shown in Table 1. The total number of operations in the table includes commercial and general aviation (Dubrovnik Airport, 2018).

Table 1
Number of operations on the Dubrovnik airport from 2010 to 2017

Year	Number of operations	Increase/decrease in %
2010	15,539	-
2011	16,050	+ 3.29%
2012	16,216	+1.03%
2013	16,126	- 0.56%
2014	16,492	+2.27%
2015	16,852	+2.18%
2016	19,244	+14.19%
2017	21,496	+11.71%

Source: (Dubrovnik Airport, 2018)

Continued growth in passenger traffic, rising tourist demand as well as the unstable political situation in reciptive tourist destinations in North Africa and the Middle East has resulted with expanding growth in traffic at Dubrovnik Airport and other coastal airports in Croatia. By construction of a new additional passenger terminal in 2017 enabled DA to increase the number of available slots (Fig. 1).

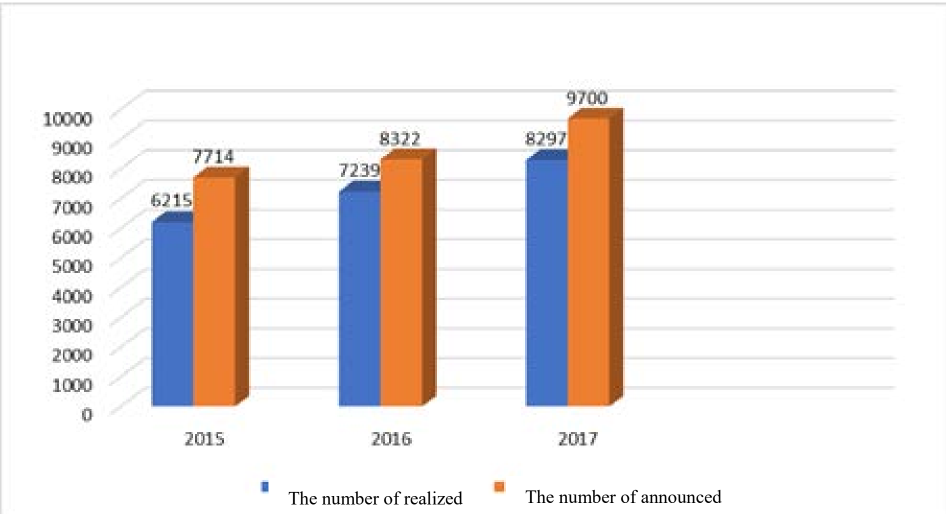

Fig. 1.
The number of realized and announced slots at DA in the period 2015-2017
Source: (Dubrovnik Airport, 2017)

Based on graph 1, the growth of allocated and realised slots in the period from 2015 to 2017 was significant. The main reasons for not realizing allocated slots are:

- less passengers in pre-season and post-season;
- the capacity fulfillment in peak season;
- other reasons such as canceling airline operations due to low ticket sales, excessive carrier's competition and bankruptcy of certain air carriers.

Regarding to slot capacity the problems of the DA are:

- the impact of the project realization on the airport capacity (during passenger terminal construction);
- non-optimal computer system for slots allocation;
- other problems such as human factors, procedures and standards.

5.1. The Impact of Slots Allocation

Airport infrastructure capacity depends on the capacity of a particular subsystem: runway with taxiways, apron, passenger terminal (check-in counters, security check, gates) etc. (WWACG, 2018).
Airports are characterized by certain limitations regarding the available capacity, and the mentioned limits are called co-ordinating parameters. According to the IATA WSG manual, the co-ordinate parameters are defined as technical, operational and environmental limits at the airport.
Coordination parameter depends on the airport type and can be categorized into four main groups (WWACG, 2018):

- environmental;
- Air Traffic Control;
- apron and runway;
- passenger terminal.

5.1.1. Enviromental Parameters

The environmental parameters that influence declared airport capacity are: maximum number of aircraft operations, noise limits, prohibition of night operations, reducing the maximum number of aircraft operations etc. (WWACG, 2018).
Limitations on the aircraft operations over a given period are introduced due to the impact of the airport's operation on the environment and population living in the vicinity of airport. Aircraft operations at the DA is determined by the declared runway and taxiways capacity of seven arrivals and seven departures per hour or 14 mixed operations hourly.
The maximum number of aircraft movements is limited by working time. During the summer working hours of the airport are from 04:00 to 21:00 UTC, and in winter from 05:00 to 21:00 UTC. Operations can be performed out of the working hours only if an agreement is made with the Flight Scheduling Coordinator and Traffic Dispatcher.

5.1.2. Runway Capacity

The maximum runway capacity at the DA is 43 aircraft operations (Republic Croatia, 2018) significantly higher than the declared capacity, 14 operations. The reason is that the maximum capacity is planned with the reconstruction and extension of a current maneuvering area.
Coordinating parameter of the current runway capacity at DA is not a limiting factor for slot allocation process.

5.1.3. Capacity of the Aircraft Parking Positions at the Apron

The DA apron consists of commercial aircraft and general aviation apron. Total surface area is approximately 110,000 m² (Republic Croatia, 2018). At the apron for commercial air carriers there are 19 fixed parking positions, mainly for airplane ICAO code letter C (Republic Croatia, 2018). Alternatively, there are also three superimposed positions for wide-body airplanes ICAO code letter E. The capacity of apron based on two configurations is shown in Table 2.

Table 2
Apron capacity of two basic configurations at the DA

ICAO code letter	Configuration 1	Configuration 2
C	12	4
D	7	7
E	0	3
Total number of parking positions	19	14

Source: (Republic Croatia, 2018)

Table 2 shows that the DA does not have the capability to handle aircraft code letter F. The current capacity of DA apron is sufficient to meet the high traffic demand even in the peak period. The DA's maximum number of commercial airplanes on the apron at any time may not exceeds 10 aircraft according to DA standard operation procedures.

5.1.4. Passenger Terminal Capacities

Up to 2017 the passenger terminal capacity has been limited aiport capacity component, the most critical co-ordination parameter was the capacity of the passenger security check. If one X-ray machine can screen approximately 200 hand baggage per hour, i.e it is possible to carry out a security check for 1,600 passengers per hour using all eight X-ray devices installed in the new passenger terminal "C" (Republic Croatia, 2018).

In 2017, a new additional passenger terminal was opened, and passenger terminal capacity increased from 2 to 3.5 million passengers a year (table 3).

Table 3
Passenger terminal capacities before and after opening of terminal "C"

Passenger terminal capacities in 2016	Passenger terminal capacities in 2017
17 passenger and baggage check-in counters	34 passengers and baggage check-in counters
10 gateways (8 international and 2 domestical)	16 gateways (14 international and 2 domestical)
4 X-ray devices for hand baggage	8 X-ray devices for hand baggage
3 metal detector doors for security check	6 metal detector doors for security check

2 passenger boarding bridges	4 passenger boarding bridges
8 arrival passeport control counters	8 arrival passeport control counters
3 departure passeport control counters	3 departure passeport control counters
3 carousels for reclaim	4 carousels for reclaim
Terminal capacity 2 million passengers yearly	Terminal capacity 3,5 million passengers yearly

Source: (Author)

Table 4 shows the number of aircraft movements and the number of passengers during the relevant peak hour on the DA in 2011 and 2016, as well as forecasts for year 2022 and 2032 (Republic Croatia, 2018).

Table 4
The total number of passengers and aircraft operations during the relevant peak hour on the DA in 2011 and 2016 and forecasts for year 2022 and 2032

Year	Aircraft operation in the relevant peak hour	Number of passengers in the relevant peak hour
2011	7	978
2016	9	1,315
2022	13	1,920
2032	20	2,916

Source: (Republic Croatia, 2018)

After the construction of a new passenger building in 2017, the capacity of the apron and the passenger terminal is more harmonized, and the capacity of the passenger terminal satisfies the capacities of the apron as well as runway and taxiways.

5.3. Process and Basic Principles of Slot Allocation at the Dubrovnik Airport

For slot allocation process Dubrovnik Airport is using computer software *Timetable* (Fig. 2). This software is a part of NIKO AS DCS system, main software system at the Dubrovnik Airport.

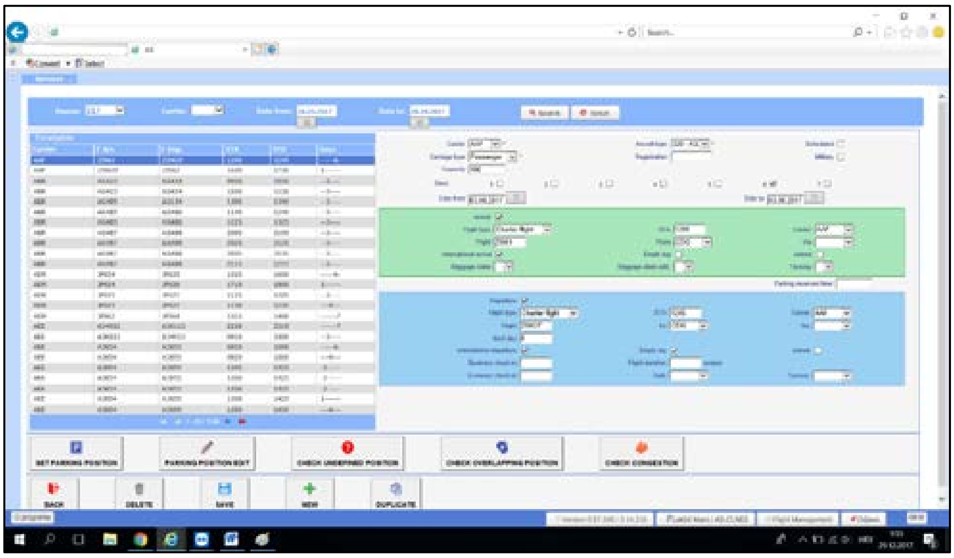

Fig. 2.
Timetable application in computer program NIKO.AS.DCS
Source: (Dubrovnik Airport, 2017)

Timetable supports flight and slot data imputs. This software supports overview of slots allocations on monthly, weekly, daily, and hourly base so that the Flight Scheduling Coordinator could track the capacities and adjust slots to meet the declared capacity.
Timetable is the main database of the Departure Control System (DCS). The *Timetable* records all the flights that air carriers announce and assigns authorized time to the carriers. The software consists of three main parts: basic data, arrival and departure flights data.
The basic data contain information about air carrier, the period in which flights are planning to be realized, the type and capacity of the aircraft, arrival and departure flight numbers, arrival and departure airport. An air carrier must provide certain flight data such as: flight type (regular, charter or general aviation), required time of arrival and departure etc. All the data are shown in Figure 2.

The *Timetable* software is associated with all applications within DCS and is used as a basic database for various DA systems and subsystems and is also used for traffic statistics, traffic forecasts and analytical purposes. Timetable displays all the slots on a specific day and automatically assigns parking positions.
The DA does not apply directly the concept of historical slot rights because airport is classified as a scheduled facilitated airport level 2. All planned operations in flight seasons are agreed between the flight schedules manager and the air carriers based on a voluntary agreement. The Flight Scheduling Manager considers the slots time which are assigned to regular carriers from the previous season and, by prior arrangement with the carrier, allocates the same time for the new flight season. Thus, the flight schedule manager gives a certain advantage to carriers who have been operating on DA for many years.
New carriers can operate in almost all periods except in specific peak periods due to the DA declared runway capacity. Such periods in 2017 were in the morning of Thursday, Saturday and Sunday at the peak summer season when the capacity of the runway was congested.

6. Conclusion

In recent years, global demand for air transport has grown at an annual rate of roughly 6%, and the available capacities at the most congested airports in the Europe and the world have not followed the growth trend. Lack of capacity is caused by lack of investment in airport infrastructure. Therefore, an aerodrome slots and authorized time systems has been introduced to ensure that aircraft operations are planned in accordance with the airport capacity to avoid delays.
The slot allocation system in the EU is based on the historical rights i.e. air carriers must satisfy the *Use it or Lose it* rule. This rule requires that the allocated slots has been used at a minimum of 80% during the period they are allocated. Advantage of historical rights during the slot allocation process is extremely favorable to the dominant air carriers, and the vast majority of slots on congested airports are used by dominant carriers. Thus, new carriers receive slots outside peak times resulting with nonoptimal flight time.
At the Dubrovnik Airport, the declared capacity of 14 aircraft operations per hour is mainly sufficient for current traffic demand. On the level 2 airport, the scheduling of authorized time is performed by the flight schedule manager. *Timetable* computer program is used for this proposed and represents an integral part of the NIKO.AS airport main software system at the Dubrovnik airport.
The number of aircraft operations are growing continuously at DA, but certain number of planned operations were cancelled. Reasons for canceling a number of announced operations were less passengers/tourists in pre and post season, congestion in peak hours of certain days in the summer and bankruptcy of certain carriers such as the Monarch Air who operated with significant number of flights at the DA.
DA coordinating parameters, runway and apron capacity mainly satisfying traffic demand. The new passenger terminal "C" significantly increased the capacity of the passenger terminal, which was early the main cause for the introduction of authorized times. By increasing capacity, congestion has been reduced in peak periods, especially for passenger and baggage check-in and passenger and hand baggage security check. The capacity of the check-in counters is doubled as well as the capacity of the security check units. The DA is currently meeting all the criteria for providing services to passengers at "C" level according to IATA recommendations.
Coordination parameters, whose capacities may be critical, especially during peak periods, are the capacities of passports and identity documents control counters on the arrivals and departures. After completion of the reconstruction of the runway and the construction of additional taxiway, it is reasonable to expect the DA carry out capacity analysis and to define a new declared capacity which will be greater than the current one.
The existing authorized times at DA airports gives satisfactory results and enables optimum capacity utilization. Certain corrections should be made primarily relate to the administrative constraints present at the level 2 airports. Future improvements should relate to redefining the administrative process of historical rights. The above rule is applied informally at the level 2 airports and the formalization of the mentioned rule should be established.

EUROPEAN AIR TRANSPORT MARKET UNDER INFLUENCE OF COOPERATIVE ARRANGEMENTS

Maja Ozmec-Ban[1], Ružica Škurla Babić[2]
[1,2] *Faculty of transportation and traffic sciences, University of Zagreb, Croatia*

Abstract: European air transport plays a vital role in the European economy. Liberalization of European air transport market combined with the ever-increasing permeation of Internet in the booking systems brought airlines into unenviable position. European full service carriers, as well as flag carriers, are highly exposed to competition from low cost carriers on short haul markets. On the long-haul markets they are exposed to competition from the Gulf airlines, including Turkey. These threats caused further airline industry consolidations that were various and multiple. Consolidation can be recognized in alliances, mergers and take-overs, but also bankruptcies of financially weak airlines. The paper provides an overview of European air transport market in the last decade considering various modes of cooperative arrangements and business models.

Keywords: European air transport, full service carriers, low cost carriers, alliances.

1. Introduction

Until the EU Third package of liberalization measures in 1993, EU routes were monopolized by EU so called flag carriers such as Air France, British Airways, Lufthansa, KLM and so on. After the removal of restrictions on market entry, capacity, frequency and pricing, and a removal of cabotage rights in 1997, new players exploited the opportunity and entered the European market in the second half of 1990s'. These new players were low-cost carriers (LCCs) which competed full service carriers (and flag carriers) in short-haul market, and Gulf carriers which competed full service carriers in long-haul markets. According to Vidović, Steiner and Škurla Babić (2004: 2) LCCs are airlines that provide transportation at lower price while eliminating many services that full service carriers provide, such as free in-flight service and extra baggage. They operate short-haul flights from secondary airports and provide no service onboard, having one type of aircraft in fleet (Ryanair and easyJet). A term "Gulf carriers" is used for airlines based in a country alongside Persian Gulf, but mostly used for these three: Etihad Airways (founded in 2003, based in Abu Dhabi), Emirates Airline (founded in 1985, based in Dubai) and Qatar Airways (founded in 1993, based in Doha). These three airlines have expanded aggressively and are creating an increasingly global network (Dresner et al, 2015: 31) and compete head-to-head with European, Asian and American carriers in international markets.
Over the last 30 years a series of consolidations and bankruptcies in European (and global) air transport market began to occur. Liberalization, while providing market access to new players, has led to a wave of numerous mergers and take-overs (or acquisitions) of full service carriers, and their formation into global alliances around the globe. For the most part, mergers and take-overs are quite similar - two previously separate firms are combined into a single legal entity. A merger is a result of a mutual decision of two companies to consolidate and to become one entity. Merger is often described as a decision made by two "equals". On the other hand, a take-over is a purchase of a smaller company by a larger one. A take-over can produce the same benefits as a merger, but it does not necessarily have to be a mutual decision of the two companies in question. Thereunto, full service carriers began to form alliances to broaden their networks. Over the years many alliances have emerged, and many have failed, but three most prominent alliances were forged in the late '90s and still exist: Star Alliance, SkyTeam and oneworld. The purpose of the paper is an overview of European air transport market in the last decade in terms of different cooperative arrangements of full service carriers.

2. Mergers and Take-Overs in Europe 2008 – 2017

During the era of flag carriers, bankruptcies and take-overs were rare in the European air transport market. However, they've become more often and have had a significant impact on the market function and competition.
Following the global financial crisis in 2008, air transport market went through significant consolidations. In the US, Delta Air Lines merged with Northwest Airlines in 2008, United Airlines merged with Continental Airlines in 2010, Southwest Airlines and Air Train Airways merged in 2011 and in 2013 American Airlines merged with US airways. Accordingly, several mergers (Table 1) occurred in Europe in the last decade.
Popularity of mergers and take-overs has increased due to liberalization, globalization and technological development. Mergers have become a popular practice in aviation, since the "key concept of merger is that a company can extend its business and create shareholders' value by purchasing another company" (Hsu and Flouris, 2017).

Table 1
Mergers, take-overs and bankruptcies of chosen air carriers in Europe from 2008 to the end of 2017

Year	Airline	Mergers, take-overs or bankruptcies
2008	KLM	Take-over of Martinair
2009	Lufthansa	Take-over of Germanwings Take-over of Brussels Airlines

[1] Corresponding author: mozmec@fpz.hr

Year	Airline	Mergers, take-overs or bankruptcies
		Take-over of British Midlands Take-over of Austrian Airlines
	SAS	SAS Norge, SAS Sweden, SAS Denmark and SAS International merged into SAS Scandinavian Airlines
	Alitalia	Joint venture with Air France-KLM group and Delta Airlines
2010	Lufthansa	Take-over of Eurowings
2011	IAG	Merger of British Airways and Iberia into IAG
	British Airways	Integration of British Midlands into BA
2012	airberlin	Etihad acquired 29,21% share in Air Berlin share hold
	Malev	Bankruptcy – ceased operation
	Air Serbia	Etihad acquired 49% share in Air Serbia share hold
2013	Darwin Airline	Etihad acquired 33% share in Darwin Airline share hold
	Alitalia	Etihad acquired 49% share in Alitalia share hold
2014	Germanwings	Merged fully into Eurowings (Lufthansa Group)
2015	Air Lituanica	Bankruptcy – ceased operation
	Estonian Air	Bankruptcy – ceased operation
	Nordica	Formed after bankruptcy of Estonian Air as Estonian flag carrier
	Darwin Airline	Etihad sold its stake to Adria Airways
2017	Monarch Airlines	Bankruptcy - ceased operation
	airberlin	Bankruptcy after Etihad pulled financing – ceased operations
	Alitalia	Bankruptcy after Etihad pulled financing – continue to operate due to governmental loan
	Darwin Airline	Bankruptcy – ceased operation

Source: gathered by the authors

The major benefit of mergers is cost rationalization (Vasigh, Fleming & Tacker, 2016: 16). Since the airline industry exhibits large economies of scale, merged airlines can spread their high fixed costs over a greater network. While some see mergers as solely positive outcome, European Commission is concerned that a change towards a more concentrated market might reduce competition. Following that concern, in 2004 Council Regulation (EC) no. 139/04 on control of concentrations between undertakings (EU Merger Regulation, 2004) was adopted. This EC Merger Regulation gives the European Commission authority to make decisions regarding potential mergers and take-overs. When two or more airlines (of which one is an EU carrier) decide to merge they need to notify the European Commission (Nemeth and Niemeier, 2012: 45). If the merger leads to a dominant position on a given EU route, the Commission introduces remedies or prohibits the merger. Remedies are simply conditions under which a merger could be approved, such as:

- surrender of slots at congested airports;
- interlining and codeshares obligations;
- open frequent flyer programs;
- freezing or reducing frequencies;
- price reduction mechanism;
- sale of assets.

Lufthansa and KLM were one of the first airlines faced with European Commission new rules. In only few years Lufthansa has finalized five mergers, as seen in Table 1. Lufthansa took over Austrian Airlines in 2009. Two airlines had many overlapping routes. Origin/points of destination impacted by the merger were: Vienna-Stuttgart, Vienna - Cologne/Bonn, Vienna-Frankfurt, Vienna-Munich and Vienna-Brussels. The Commission concluded that Lufthansa is to make available slots at Vienna and/or Frankfurt and/or Munich and/or Cologne/Bonn and/or Stuttgart and/or Brussels (COMP/M. 5440, 2009) to allow one or more prospective new entrant(s) to operate a new or additional competitive air service on the following identified city pairs. Just like in the Lufthansa-Austrian case, European Commission decided that in the case of British Airways and Iberia merger, British had to give up their slots on Heathrow and Gatwick routes to competitors, but only if the competitors have already exhausted their slot portfolio (COMP/39.596-BA/AA/IB, 2010). From this, and other decisions of European Commission regarding merger control, it can be seen that in the most cases where an airline gains full control of the other airline, the most common remedy is surrender of slots at congested airports.

There is an interesting pattern seen in a Table 1, regarding bankruptcies of European carriers, linked with the Gulf carrier Etihad Airways and its pulling out of financing of their insolvent equity partners, such as Darwin Airline, airberlin and Alitalia. Etihad Airways' equity partner network at the beginning of 2017 included airberlin, Air Serbia, Air Seychelles, Alitalia, Jet Airways, Virgin Australia and Etihad Regional, and represented the world's seventh largest global grouping of airlines. However, since the CEO who designed a plan to gain proxy presence of Etihad Group in different countries, obtaining stakes in different airlines has left the Etihad, Etihad has changed its business plan and stopped financing their risky investments, airberlin and Alitalia. This decision weakened further airberlin and Alitalia, causing airberlin to completely cease operations and Alitalia to file for bankruptcy, continuing to operate but relying on Italy government support.

3. Global Airline Alliance

According to (Ohmae, 1989) "Companies are just beginning to learn what nations have always known: in a complex, uncertain world filled with dangerous opponents, it is best not to go alone". Evans (2001: 229) defined the concept of a strategic alliance as "a particular horizontal form of inter-organizational relationship in which two or more organizations collaborate, without the formation of a separate independent organization, in order to achieve one or more common strategic objectives".

The basic strategy of every airline is to weaken competition on certain routes and to gain market share, so it is no wonder that alliances were formed. Since the deregulation and liberalization on both sides of the Atlantic have impacted the airline market, full service carriers developed a strategy to form global alliances which will expand their global network and provide them comparative advantage versus low cost carriers. The first truly global alliance is Star Alliance. It was formed in 1997 between United, Lufthansa, SAS, Air Canada and Thai Airways. Shortly after formation of other alliances followed:

- oneworld alliance in 1998 was formed between American, British Airways, Qantas and Cathay Pacific,
- Qualiflyer in 1998 included Swissair, Sabena, Turkish Airlines, Air Liberte and TAP Portugal,
- SkyTeam in 1999 formed between Delta, Air France and Aeromexico.

However, Qualiflyer alliance was dissolved in 2001 after Swissair demise, and ultimately in 2002 when it was bought by the Lufthansa group and incorporated into Star Alliance.

Timeline of member airlines participation in SkyTeam
Source: Airline Business Airline Alliance Survey, September 2017

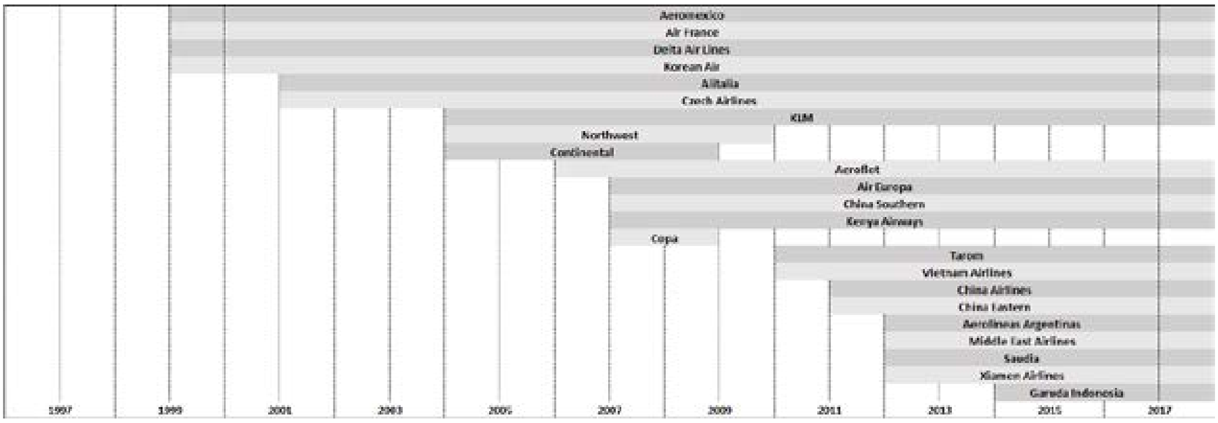

Fig. 3.
Timeline of member airlines participation in oneworld
Source: Airline Business Airline Alliance Survey, September 2017

The three existing global alliances have expanded over the course of two decades, which can be seen in Fig. 1, 2 and 3. They provide geographical coverage to all areas of the world. Expansion and optimization of alliance members route network provides greater flight options to passengers. Combined, these three alliances hold 56.9% (Table 2) of share in total nonstop scheduled capacity offered in year 2017. Dominantly full service carriers are members of global alliances, with an exception of Qatar Airways, Gulf carrier that became a member of SkyTeam in 2013.

Table 2
Alliance statistics

Column1	Star Alliance	SkyTeam	oneworld
Member airlines	28	20	14*
Revenue ($ bn)	181	147	134
Countries Served	191	177	157
Destinations served	1218	1065	978
Share in scheduled capacity offered	22.7%	18.3%	15.9%

**since Air Berlin ceased operations in late 2017, it is no longer part of oneworld alliance*

4. Development of Full Service Carriers

The business model of full service carriers is under increasing pressure, on short-haul as well as on long-haul market. According to (Eurocontrol Seven-Year Forecast, 2018) LCCs accounted for over 31% (versus 26% in year 2013) of the European flights in 2017. Figure 4 shows the comparison of total share of European flights per market segment shows in 2017. Even though full service carriers do own a significant market share in 2017, the comparison indicates a negative trend in full service carriers market share in regards to LCCs in the total supply of intra-EU flights. It is presumed that due to the stagnation in growth in European market (mostly UK and Ireland), some LCCs will develop a new strategy, and increase route range, which will generate a so-called hybrid LCCs (Burghouwt et al., 2015). This occurrence might provoke the cannibalization of full service carriers.
According to the same report (Eurocontrol Seven Year Forecast, 2018) on the extra-EU market, first partner is USA, which was a number one destination from European countries, and the second was Russian federation. However, the third one was The United Arab Emirates with 164 daily departures on average and an increase of 1.2% compared with 2016. The growth of Gulf carriers is increasing due to their massive network and their hubs that provide passengers great connectivity to beyond markets (Australia, North and South America, Africa and Asia).

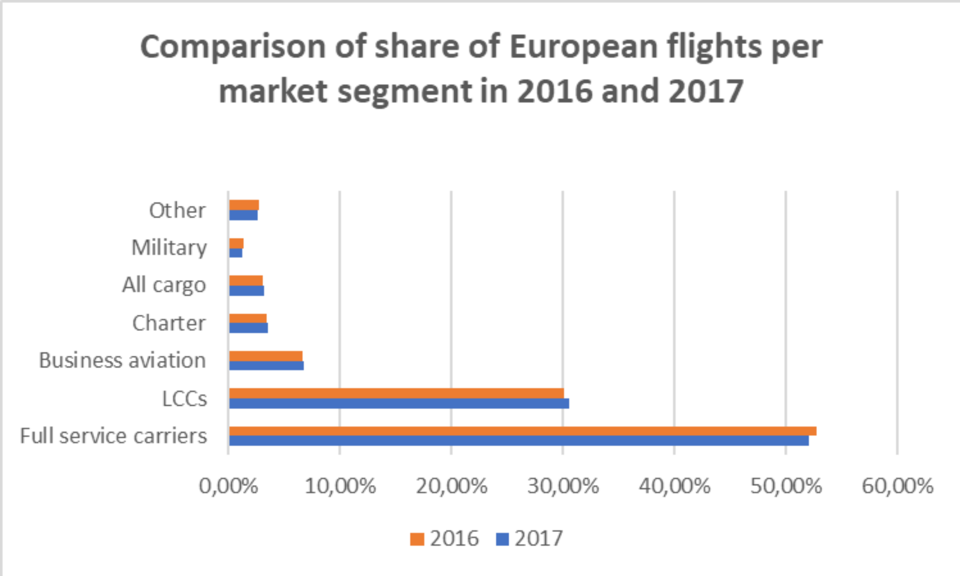

Fig. 4.
Comparison of share in European flights per market segment in 2016 and 2017
Source: Eurocontrol Seven-Year Forecast, February 2018

The effects of anti-monopolization due to rise of new players on the market, as well as merger control regulations have pushed full service further to consolidation. The increase of mergers in European market, with the increase of number of alliance members, show that full service carriers are looking for an optimal collaborative arrangement to remain on the market, preferably gaining more market share and financial gain. It is evident that full service carriers will be increasingly exposed to their opponents (LCCs and Gulf carriers). Therefore, further industry consolidation might be expected, along with continuity of bankruptcies of financially week airlines, but also the optimization of hub-networks. Idea of integration of LCCs into global alliances so that they could be feeders to full service carriers network is no longer just an idea: Vueling (Spanish LCC) started to optimize their schedule to contribute to Iberia financial results (Burghouwt et al., 2015).
The invasion of Gulf carriers into market that was previously dominated by Europe an US full service carriers has raised the concerns on "fair competition". Various mechanisms are being considered currently on a global scale (since it is a global issue) to address the issue of "fair competition". One of them is to include "fair competition" clauses that will be formulated by European Commission, E States or ICAO in international agreements on air transport, and the other could be requesting more transparency on the financials of the carrier in question before granting any traffic rights.

5. Conclusion

There are numerous factors that effect the consolidation of full service carriers and entire European air transport market. All of them are derived from the liberalization of air transport market (regionally and globally). In the past 30-year period the regulative framework has changed and adapted countlessly to the needs of the market. However, regulatory framework to be differed takes time. At the same time, all the airlines on ne global market looks for a cooperative arrangement that is the best option to their prosperity. Most of the major players participate in many forms of cooperative arrangement, pulling even smaller players into their networks: via mergers or full take-overs, or via forming alliances global networks. This overview of European air transport market gives a sense of whet are the threats to a full service carriers business model, and gives a input to a further more detailed research of efficiency of merger control remedies in European air transport market, as well as the impact of global alliances on specific route networks (extra-EU routes operated by European full service carriers and their alliance partners vs. Gulf service carriers).

DISPATCH RELIABILITY FROM ASPECT OF AIRCRAFT MASS AND BALANCE

Ivan Jakovljević[1], Ljubiša Vasov[2], Petar Mirosavljević[3], Branimir Stojiljkovivić[4]
[1,2,3,4] *University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, Belgrade, Serbia*

Abstract: Dispatch reliability is an important factor in aircraft operation. If the aircraft is not available in required moment, even for a short period, it can have a great effect on the airline which can lead to bad reputation – losing the slot, canceling the flight, delays. Mass and balance is a critical part in aircraft operation, and since all airlines tend to maximize the payload while remaining within defined limits, this task can sometimes lead to a delay. There are many parameters which can influence mass and balance process, and some aircraft are more convenient than the other. Parameters observed were MAC limits, load accessibility, cooling surfaces, lock positions, etc. Also, statistical values are included, which were measured in live operation. TOPSIS method was used to rank the aircraft, while importance of parameters was given by a group of experienced experts in the field, which directly influenced the weights of criteria, defined by Delphi method. Both wide body and narrow body aircraft were included in the research, and they were finally ranked by the dispatch reliability from aspect of mass and balance.

Keywords: Dispatch reliability, mass and balance, TOPSIS.

1. Introduction

Dispatch reliability prediction methods present an important step in delay prevention (Bineid et al., 2003) on both short haul and long haul flights. Delay codes are attached to aircraft systems in order to define and prevent leading causes for the delays. Performance parameters are taken into account, and the findings could be applied to aircraft in conceptual phase.

Dispatch reliability has increased due to new maintenance models („on condition“) as it is stated in the "BAC One-Eleven = reliability" (1974). Carriers tend to maximize dispatch reliability, and each aspect leading to the aircraft not being reliable at the scheduled time of departure, should be properly analyzed.

Load factor and aircraft utilization have a high effect on the operational efficiency (McLean, 2006). It is concluded that high loading factor can lower operational efficiency.

TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) method can be used to analyze aircraft operational parameters (Čokorilo et al., 2010), and select optimal aircraft for regional air travel realization. Four regional aircraft types were taken into consideration, which were further evaluated by operational and technological criteria. Results were used to define the aircraft fleet.

TOPSIS method was used (Moazami et al., 2016) to analyze maintenance and repair system of Antonov 74 aircraft. They used access ratio, quality and efficiency ratio for evaluating repair systems. Conclusion was that intervals between inspections are crucial when choosing the right maintenance model, hence the proper inspection defined the best model.

Ranking of the aircraft safety when landing on a carrier was done using Fuzzy Multi-Attribute Group Decision Making (FMAGDM) (Wu et al., 2016). Landing routes were evaluated and simulated under a number of conditions.

TOPSIS was used method to evaluate anti-submarine aircraft maneuverability (Yang et al., 2014), in order to select the best aircraft for the task. Aircraft performance indicators were used as criteria by which the alternatives (aircraft) were analyzed.

The best aircraft for air combat were selected using TOPSIS method (Wang et al., 2008), by measuring the aircraft performance. TOPSIS was used to provide crisp performance value, and to provide the ranking of the aircraft. Also, fuzzy AHP method was combined with the TOPSIS.

Each aircraft has performance values and indicators which define its suitability for a certain task. Wide body aircraft are used for long-haul flights and high payload values, narrow body aircraft are usually used for short haul flights, combat military aircraft have a high maneuverability due to requirements of the task, etc. One of the aspects of aircraft operation is dispatch reliability. If the mass and balance task is difficult, it is best to select optimal aircraft for the operation. As it has been shown, TOPSIS method is convenient for selecting the aircraft for certain task, when different performance indicators are considered. This research, in a same way offers the insight into important criteria from the aspect of mass and balance reliability, and uses TOPSIS to evaluate the most reliable aircraft from the mass and balance reliability aspect. Further, this reliability can be considered as one of the many factors for the airlines, when selecting the best aircraft for the task.

2. Selecting the Criteria

There are many specific aspects that affect the mass and balance, and the preparation of loading instruction report. Predicted payload, special and dangerous goods limitations, cargo compatibility, aircraft performance and route conditions, as well as predicted fuel and zero fuel mass. At the moment of issuing a loading instruction report, many values are predicted and not definite (number of passengers, baggage mass, fuel values). However, during the certain phases, these numbers become final (check in closure – number of passengers, baggage mass; captain fuel message –

[1] Corresponding author: ivan.b.jakovljevic@gmail.com

fuel figures). When these numbers become final, some modification has to be done in order to have a proper loading and remain within the limits for the loadsheet.
This means that aircraft parameters which offer flexibility and quick modification in the case of loading change are very important factors affecting the dispatch reliability at the given moment (Scheduled time of departure – STD).
Also, possibility to create loading instruction report without many limitations (cooling surfaces, reachability, large MAC envelope values), can help avoid problems and last-minute changes to the loading.
Some of the parameters can't be easily measured, and statistical values can indicate dispatch reliability.
Considering all these parameters following indicators are used as criteria for analyses of dispatch reliability from aspect of mass and balance:

where
Ps – represents probability that the aircraft will not be usable (out of trim or overweight) based on statistical analyses of the sample (values 0-1)
MACmin – percentage of the mean aerodynamic cord usable for weight and balance at minimum values for ZFM, TOM, LM (mean value of the three; values 0-1)
MACmax - percentage of the mean aerodynamic cord usable for weight and balance at maximum values for ZFM, TOM, LM (mean value of the three; values 0-1)
MACnormal - percentage of the mean aerodynamic cord usable for weight and balance at middle values for ZFM, TOM, LM (mean value of the three; values 0-1)
Combining the statistical values with MAC values creates a most important indicator for mass and balance reliability. MAC envelope is an area in which the position of aircraft center of gravity (CG) at ZFM, TOM and LM should be, in order to have an aircraft within defined limits. The higher the MAC value and lower the *Ps*, it is more probable that the aircraft would be in defined limits. This combination of statistical probability that the aircraft would be within given limits, and the area (MAC envelope) is defined as dispatch MAC factor.
Dispatch MAC factor *DMF* for *i* type of aircraft is then calculated as:

$$DMF_i = (1 - Ps_i) \cdot \frac{MACmin_i + MACmax_i + MACnormal_i}{3}$$

Table 1
Dispatch MAC Factor Values For Selected Aircraft

Aircraft type	A319	A320	A321	A330	A350	B747
DMF	0.1256	0.138603	0.0929	0.121629	0.137926	0.149296

However, CG position being within the defined limits isn't the only condition by which the aircraft dispatch reliability is measured. Aircraft could be within the limits with the high *DMF*, but still not provide proper cooling for perishable goods, or a good locking position for the pallet or ULD. Also, total mass can be within MAC, but at certain position can still cause overweight due to floor capacity limit. This capacity, combined with a given volume on that position results in compartment capacity.
When considering the mass and balance reliability, there are other quantity and quality indicators, such as:
Cs – cooling surface in the holds (number of holds with cooling available divided by total number of holds, values 0-1), very important for handling perishable goods;
Rs – reachable surface (number of doors divided by number of holds, values 0-1);
Us - usable surface (number of positions divided by number of positions available for use – for example B747 aircraft has container positions without hooks);
Cc – compartment capacity, (capacity measured for each position – when exceeded, it would be overloaded).

Table 2
Quantity/Quality Indicators by Aircraft Type

i/j	*DMF*	*Cs*	*Rs*	*Us*	*Cc*
A319	0.1256	0.4	0.6	1	1045
A320	0.138603	0.375	0.375	1	1045
A321	0.0929	0.3	0.3	1	1013
A330	0.121629	0.625	0.1765	1	1587
A350	0.137926	0.6	0.15	1	1588
B747	0.149296	0.75	0.1875	0.4375	1000
Wj	1	0.3	0.63	0.37	0.67

The importance of each factor is given as a weight W_j. These weights are calculated using Delphi method based on evaluation of group of experts in the area. Group consisted of nine experts, six were Centralized Load Control (CLC) agents, two were shift Coordinators, and one was Operations manager.

2. Multi-Criteria Analyses Using TOPSIS Method

TOPSIS was defined as a method (Hwang, 1981) which ranks alternatives according to the distance from ideal and anti-ideal solution. Best alternative is the one which is farthest from anti-ideal and closest to the ideal solution. In that way, all the positive and negative sides of alternatives are observed and included into the final ranking.
TOPSIS method was used to rank the aircraft according to dispatch reliability. Aircraft type is defined as an alternative A_i, while indicators are considered as a criteria k_j. Each value presented in table 1 given for indicator j and aircraft i, is presented as x_{ij}.
First step is normalizing the table by using the following expression:

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_i^2}}$$

Also, weights need to be normalized, using the following expression:

$$W_j' = \frac{W_i}{\sum W_j}$$

Normalized table is shown (table 3).

Table 3
Normalized Indicators by Aircraft Type

i/j	*DMF*	*Cs*	*Rs*	*Us*	*Cc*
A319	0.40	0.31	0.73	0.44	0.34
A320	0.44	0.29	0.45	0.44	0.34
A321	0.29	0.23	0.36	0.44	0.33
A330	0.39	0.48	0.21	0.44	0.52
A350	0.44	0.46	0.18	0.44	0.52
B747	0.47	0.57	0.23	0.19	0.33
Wj’	0.34	0.10	0.21	0.12	0.22

Next step is weighing the table, and defining the criteria type by min/max. Weighing of the table is done by using the following expression:

$$V_{ij} = r_{ij} \cdot W_j'$$

Weighed table is shown below (table 4):

Table 4
Weighed Indicators by Aircraft Type

i/j	*DMF*	*Cs*	*Rs*	*Us*	*Cc*
A319	0.13	0.03	0.16	0.05	0.08
A320	0.15	0.03	0.10	0.05	0.08
A321	0.10	0.02	0.08	0.05	0.07
A330	0.13	0.05	0.05	0.05	0.12
A350	0.15	0.05	0.04	0.05	0.12
B747	0.16	0.06	0.05	0.02	0.07
Wj’	0.34	0.10	0.21	0.12	0.22
max/min	max	max	max	max	max

Next step is forming ideal (A^+) and anti-ideal (A^-) solution. This is done as:

$$A^+ = \left\{\left(\max_i V_{ij}\,; j \in K'\right) \vee \left(\min_i V_{ij}\,; j \in K''\right)\right\} = \{V_1^+, V_2^+, \dots, V_j^+, \dots, V_n^+\}, \qquad i = 1, \dots, m$$

$$A^- = \left\{\left(\min_i V_{ij}\,; j \in K'\right) \vee \left(\max_i V_{ij}\,; j \in K''\right)\right\} = \{V_1^-, V_2^-, \ldots, V_j^-, \ldots, V_n^-\}, \qquad i = 1, \ldots, m$$

$K' \subseteq K \rightarrow K'$ related to max type of criteria
$K'' \subseteq K \rightarrow K''$ related to min type of criteria

Ideal solution is: A^+ = (0.16; 0.06; 0.16; 0.05; 0.12)
Anti-ideal solution is: A^- = (0.20; 0.02; 0.11; 0.04; 0.03; 0.05)

Next step is consisted of measuring the distance of each alternative (aircraft type) form the ideal (S_i^+) and anti-ideal (S_i^-) solution and calculating aggregated distance (C_i) from these solutions. This is calculated as:

$$S_i^+ = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^+\right)^2}$$

$$S_i^- = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^-\right)^2}$$

$$C_i = \frac{S_i^-}{S_i^- + S_i^+}$$

$$0 \le C_i \le 1$$

If the $C_i = 0$, solution is anti-ideal, and if the $C_i = 1$, solution is ideal.
The complete distance and ranking is shown in the table below (table 5):

Table 5
Ranking of Aircraft Types

Aircraft type	A319	A320	A321	A330	A350	B747
C_i	0.697071	0.515169	0.304956	0.36871	0.390016	0.37058
Rank	1	2	6	5	3	4

Conclusion

When considering all aspects of aircraft being out of balance and/or overweight, and also the possibility of resolving such issue (accessibility of holds – door access, switching the load position – special loads on cooling positions, etc.), A319 has proven to be the most reliable, and the least likely cause of delay 31 (aircraft documentation late – loadsheet issued late due to mass and balance problem). This is caused by high compartment capacity, easy access to the load, high ratio of usable surface, and overall flexibility in resolving out of trim situations. As expected, wide body aircraft have a significantly lower ranking, due to low flexibility of solving out of trim issues (special equipment used for loading, difficult access in ULD aircraft, etc.). Also, important factor when considering the wide body aircraft is high amount of cargo, special cargo, and dangerous goods transported by these aircraft. When special load is considered, cooling surface is an important factor (B747 has a high number of holds with the cooling). Also, MAC envelope and statistics are included in DMF, which is considered as the most important criteria. A350 is the most reliable wide body aircraft, which is due to high number of compartments, high capacity, excellent envelope and fuel index influence on TOM and LAM indexes. The proposed methodology can be used by the airline when selecting aircraft for specific task, especially challenging from the aspect of mass and balance. These tasks are directly linked to maximum payload uplift, which can be difficult when aircraft performance factors are limited (high temperature, low pressure, high altitude airport, obstacles and short runway, contaminated runway, etc.). Good selection of the aircraft, helps in having the maximum payload uplift, reduced number of delays and carriage of special goods requiring cooling, ventilation or controlled temperature.

Abstract: Airports have been recognized as a critical spot when it comes to bird strike risk. Most birds fly at less than 300 m above the ground (Kazda and Caves, 2007). Therefore, flight phases that involve aircrafts low altitude such as take-off and landing are the most endangered. Considering that each area has its own specific elements that may attract birds, whenever it is feasible it is highly recommended to consider all particularities of specific airport region when analyzing the bird strike risk. This paper will analyze bird strike occurrences at Milwaukee's General Mitchell International airport. The focus of this study will be the number of confirmed cases of damage to an aircraft by a wildlife strike, and the number of cases where residue and bird remains was visually confirmed on an aircraft following a strike. Other cases where only remains of wildlife were found with no report of a strike, reported strikes but without aircraft damage or visual confirmation of residues, and other examples, will be displayed to show the complexity of the topic of wildlife strikes at an airport. Consequence of bird strike varies and depend on numerous elements. Some of them such as aircraft type, and part of the aircraft that suffered the impact will be analyzed as well. Data from the years 2013 to December 16, 2016 are used for this analysis.

Keywords: bird strike risk, wildlife hazard, airport, air traffic safety.

1. Introduction

Increasing air traffic volume and populations of many bird species put pressure on all aviation stakeholders to participate in bird strike risk mitigation process. The bird strike risk in aviation requires a comprehensive approach and a detailed analyze of historical data (Nešić and Čokorilo, 2018). Proper reporting of wildlife strikes will determine quality and accuracy of data which will be used for the risk evaluation and in the process of making decision which prevention measures will be applied. The bird species are often poorly identified, and a lot of other valuable data, such as weather details, are frequently missing from bird strike reports. In addition, bird strikes that did not cause any damage were often not reported (Nikolajeff, 2014). Beside flight crew other subjects may submit bird strike report to aviation authorities like technical staff engaged on maintenance and airworthiness related tasks, air traffic controllers, airport or aircraft handling employees (Nešić and Čokorilo, 2017). The most important is that all parties in aviation should be involved in this problematic thus each wildlife strike shall be timely reported. Per International Bird Strike Committee (IBSC) Standard 6 bird/wildlife occurrences are divided in 3 categories: confirmed strikes, unconfirmed strikes and serious incidents. According to (IBSC, 2006) previously mentioned categories are defined as follows.
Confirmed strikes:

- Any reported collision between a bird or other wildlife and an aircraft for which evidence in the form of a carcass, remains or damage to the aircraft is found;
- Any bird/wildlife found dead on an airfield where there is no other obvious cause of death.

Unconfirmed strikes:

- Any reported collision between a bird or other wildlife and an aircraft for which no physical evidence is found.

Serious incidents:

- Incidents where the presence of birds/wildlife on or around the airfield has any effect on a flight whether or not evidence of a strike can be found.

The wildlife hazard may have multiple impacts, of course, the most important is effect on flight safety. According to Federal Aviation Administration (FAA) wildlife strikes have killed more than 262 people worldwide and destroyed over 247 aircraft since 1988. In most cases wildlife strike won't affect flight safety. During the decade of 1999-2008 in total 71 accidents occurred due to a bird strike. Of these only 6 led to fatal injuries (EASA, 2009). Bird strike effect on flight depend on many factors like bird's mass, flight phase, which part of the aircraft suffered the impact and so on. The aircraft parts most likely to be damaged are the nose, radome, fuselage and the wing (EASA, 2008). Beside safety effect wildlife strikes also generate additional costs to aviation industry. Reported bird strikes have increased more than six-fold from 1990 to 2013 and cost an estimated $625 million annually to civil aviation in the United States (Koros and Hale, 2016). In conditions of difficult economy terms and high competition additional bird strike costs are undesirable and airlines can't afford expensive repairs, delays, cancelations and airplane withdrawal. Besides, there is whole other group of costs which amount is almost impossible to estimate, that costs are costs of lost demand, passengers' dissatisfaction, influence on company reputation and modal split (Nešić *et al.,* 2016).

2. Airport's Area and Wildlife Hazard

FAA announced that in the period from 1990 to 2015, 169,856 wildlife strikes were reported (166,276 in USA and 3,580 strikes by United States registered aircraft in foreign countries). In 2015, birds were involved in 95.8 percent of the reported strikes, terrestrial mammals in 1.6 percent, bats in 2.3 percent and reptiles in 0.3 percent. In commercial air transport, bird strikes usually take place during departures and approaches below 500 feet (Dolbeer, 2006). Using various sources of information (ICAO, UK CAA, EURBASE) it can be derived that most of the bird strikes occur below 2500 feet (90%-93%), and the majority occurs at altitudes below 200 feet (64%-75% depending on data source) (EASA, 2009). When it comes to wildlife hazard focus should be on the airport's area where most likely bird strike will occur. Airports should conduct an inventory of bird attracting sites within the International Civil Aviation Organization (ICAO) defined 13km bird circle, paying particular attention to sites close to the airfield and the approach and departure corridors (IBSC, 2006).

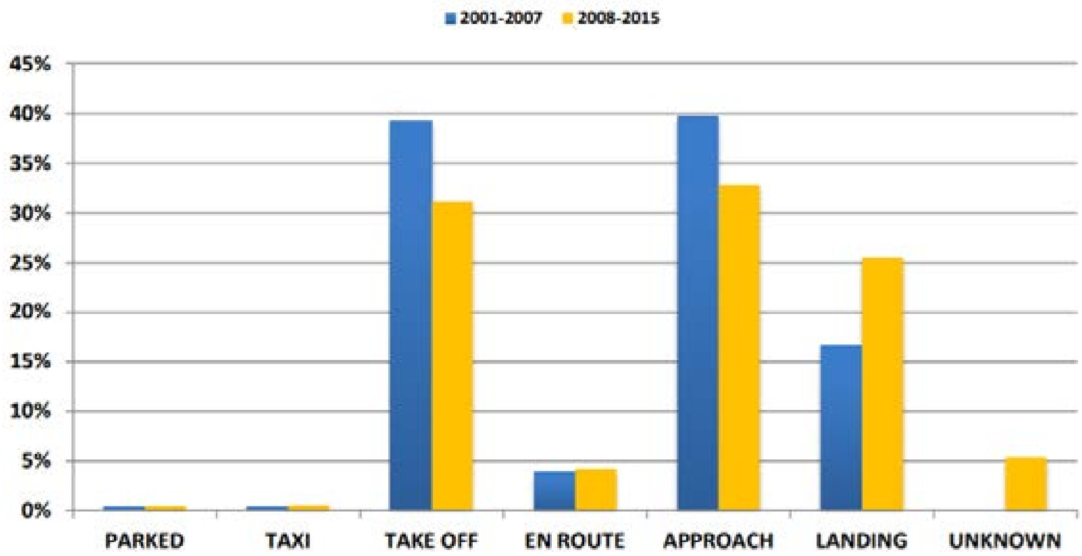

Fig. 1.
Percentage of Reported Strikes Based on Flight Phase where Collision had Occurred
Source: (ICAO, 2017)

2.1. Airport Areas with Higher Bird Strike Risk

Beside birds other animal species may affect airport operations and cause aircraft damage, the most common are deer and coyote. This type of collisions may occur at different airport maneuvering surfaces. The crucial is the fact that focusing on airport maneuvering areas and airport complex is not enough. Hazardous wildlife attractants in the airport vicinity could be any element that provides food, water and shelter for the birds. Therefore, aquatic areas, agricultural fields and forests are very risky when it comes to bird strike risk. The previously mentioned areas are usually very large which makes wildlife management and bird strike prevention highly complex. Second type of airport risky areas are characterized by containing highly attractive elements to birds but occupy significantly smaller area comparing to first category. This are fields with freshly excavated lend, sewage or landfill areas. Sometimes certain area could temporary become very attractive to birds and those cases require immediate short-term actions to remove elements that attract birds which means that presence of temporary activities on the airport must be included in the analysis. The most common case that requires temporary actions is land excavation which is leading to insect presence on the surface (Nešić *et al.,* 2016).

Per (Kazda and Caves, 2007) special attention must be paid to the maintenance of the areas covered by grass and it is best if the grass height is kept around 20 cm or more. If the grass is higher than 20 cm, the view of the birds is limited, and they cannot move easily in the grass. Airport regulation and wildlife management responsibilities are largely matters of federal law, which governs classification, certification, federal grant funding, and operation of airports and which prescribes actions airport operators must take to evaluate and respond to wildlife hazards at airports (Rillstone and Dineen, 2013). Wildlife management plan should be developed based on previously conducted risk assessment for the specific airport. In cases where wildlife risk is low, and no corrective actions are required airport authorities should continue with area monitoring in case of unexpected changes.

3. Milwaukee's General Mitchell International (MKE) Airport

Milwaukee's General Mitchell International (MKE) airport is in the city of Milwaukee, state of Wisconsin. The airport is located in 5 miles (8 km) south downtown Milwaukee. MKE airport is classified as a medium hub commercial service airport and it is the largest airport in Wisconsin with 2,386 acres. As General Mitchell International Airport published there are five runways at, ranging in size from 10,000 feet long (a little less than two miles) and 200 feet wide, to the shortest runway of 3,500 feet long (about two-thirds of a mile long). For the year 2017 the airport had 112,169 aircraft operations, an average of 307 per day (FAA, 2018). According to Milwaukee County for 2017, 6.9 million passengers traveled through Mitchell International, an increase of 164,772 from 2016. MKE serves commercial service airlines, cargo aircraft, private and business aviation, and the Wisconsin Air National Guard. It is owned and operated by Milwaukee County, and is the largest airport in the state of Wisconsin. Also, MKE airport has a helipad which is located on the south side of the airport property.

Fig. 2.
Milwaukee's General Mitchell International (MKE) Airport

3.1. Safety Management System and Wildlife Management at the General Mitchell International Airport

Safety management processes identify hazards with the potential to adversely affect safety. These processes also provide effective and objective mechanisms to assess the risk presented by hazards and implement ways to eliminate these hazards or mitigate the risks associated with them (ICAO, 2013). General Mitchell International Airport (MKE) officially announced that a Safety Management System (SMS) has been developed. An integral part of the SMS is reliance on participation of all parties to improve safety practices at every level. MKE officials emphasized that all staff, tenants, and contractors are responsible to report hazardous conditions, accidents, incidents, or unsafe actions. No matter what role employee have at the airport, they all play an integral part in maintaining MKE's Safety Management System. As they said, *"If hazards are not reported, they cannot be corrected"*. Also, for this purpose SMS Portal has been developed, it allows all staff, tenants, and contractors to report safety hazard to the Airport Program Safety Manager. The Airport Operations department is the responsible airport authority tasked with the safety, security, and maintenance of airport facilities and the airfield.

In order to conduct successful wildlife management along with proper data collecting it is necessary to duly analyze collected data. Wildlife management often requires numerous preventive and corrective measures, but feedback of the applied measures efficiency sometimes can be omitted. A survey of 38 airports in the Canada has shown that over 75% of airports kept strike records, but less than 7% used them to measure the outcomes of countermeasure implementation (Hesse *et al.,* 2010). The FAA requires airport sponsors to maintain a safe operating environment, which means they must conduct a Wildlife Hazard Assessment (WHA) and prepare a Wildlife Hazard Management Plan (WHMP) if it is needed. Numerous actions can be taken to reduce wildlife presence in the airport areas. Risk mitigation actions that will be taken depend on airport's risk category. At the General Mitchell International airport the task of wildlife management is a responsibility of the Operations department. General Mitchell International airport Operations department works in accordance with federal recommendations, guidance and regulations of airport operations. The Airport Operations staff responsible for wildlife management at MKE airport receive a training on this topic 12 months.

3.2. Particularities of the General Mitchell International Airport's Area

Water rich areas are characterized by specific wildlife species that pose special hazards to air traffic. Birds that settle aquatic areas like loons, grebes, albatrosses, pelicans, cormorants, waterfowl, herons, egrets, rails shorebirds, gulls, tems, and kingfishers were responsible for 48% of reported strikes that involved known species and 67% of damaging strikes, 1990-1999 (Cleary *et al.,* 2000).

FAA classifies state of Wisconsin into the Great Lakes region together with Illinois, Indiana, Michigan, Minnesota, North Dakota, Ohio and South Dakota. Generally, aquatic areas are considered as areas with higher wildlife activity, especially during seasonal months. For the airports in the Great Lakes region (FAA, 2015) recommends reviewing their wildlife hazard management plan (WHMP) every 12 consecutive months or in cases: an air carrier aircraft experiences multiple strikes, an air carrier experiences substantial damage from striking wildlife, an air carrier aircraft experiences an engine ingestion of wildlife. Specific of Mitchell International airport area is that beside closeness of Lake Michigan there is also a military presence.

Fig. 3.
Milwaukee's General Mitchell International Airport is Located in the Vicinity of the Lake Michigan

Military aircrafts are especially affected by wildlife hazard due to low flight levels and possibility of bird ingestion on the aircraft with only one engine. Research of wildlife strikes in military aviation is very complex because these data are often classified. Nowadays, more and more military organizations becoming aware of wildlife hazard importance and have started sharing wildlife strake data. General Mitchell International airport is another airport with military flight activities within a restricted area. The 128th Wisconsin Air National Guard (ANG) Air Refueling Squadron Base, located on the eastern edge of the airport, maintains and operates the KC-135 aircraft. Fighter aircraft in-flight refueling activities are coordinated and monitored by the Tactical Control Flight Facility (MKE, 2017).

Fig. 4.
The 128th Air Refuelling Wing (128 ARW) Stationed at General Mitchell International Airport

4. Bird Strike Data Analysis at Milwaukee's General Mitchell International Airport Based on Historical Data

The data that is used in the paper is a collection of all entries that have been filed under "Wildlife Strike." Per the requirements by the Operations department, any report of a bird or animal strike, findings of wildlife residue, and pilot reporting of a wildlife strike through the Federal Aviation Administration's wildlife strike system are logged, an entry of Wildlife Strike must be completed. Wildlife strike reports are filed and completed by the Airport Operations

Manager, Assistant Manager, or Airport Operations Coordinator. The data used in this study has been collected from Airport Operations Department logbook system. The data was sorted manually and noted as to the findings of the logbook entry. The entries were classified into six categories of a pilot report (PIREP) (Table 1).

Table 1
The Six Categories of a Pilot Report (PIREP)

PIREP category	Description
PIREP - Negative Findings	A report of a bird strike by a pilot, where the end-result was no findings of any bird remains and/or damage to an aircraft. This is often the case when an aircraft on take-off reports a bird strike, no bird remains are found, and no reports of aircraft damage to the airport authority.
PIREP - Only Remains Found	A report of a bird strike by a pilot, often after departure, where bird remains are found, but no other information regarding damage to the aircraft.
No PIREP - Only Remains Found	A case where bird remains are found on the runway by the airport authority/inspector, and no report of a bird strike by a pilot.
PIREP - Damage Seen	Visual confirmation of damage to an aircraft by the airport authority and/or pilot after a bird strike.
PIREP - Remains on aircraft, no physical damage	Visual confirmation by the pilot and/or airport authority of bird remains on an aircraft, such as blood, or feathers, but no physical damage or indication of a repair being needed.
PIREP - Remains found, no damage to aircraft	A confirmed bird strike by a pilot, and the retrieval of bird remains on the runway by the airport authority, however no damage to the aircraft or any remains found on the aircraft after inspection by the pilot and/or airport authority.

The risk assessment process relies on reported bird strikes so reporting this kind of events in a selective way may significantly impact results (Nešić and Čokorilo, 2017). For the purposes of this study, only written confirmation by the logbook entry author of confirmed damage or residue of wildlife remains on the aircraft will be acknowledged as confirmed cases where damage was done to the aircraft, or there was a risk of damage. Due to inconsistencies in the reporting methods, many entries, for the accuracy of this study, were not classified in either group. The reason for the omission of these entries is, by the wording of the entry, there could be no confirmation of damage to an aircraft, or if visible remains were observed on the aircraft.

Historical bird strike data for the General Mitchell International airport for the period from the 2013 to 2016 have been classified based on the PIREP category (Table 2). According to these data at MKE airport there were 8 cases of damage to an aircraft by bird strike and 22 cases of residue found on the aircraft following a bird strike. There were 28 cases of confirmed bird strikes with remains found by the airport authority, but no damage to the aircraft. There were 39 cases of a report of a strike, but no findings of remains or damage. There were also 14 cases of a report of a strike with remains found, but no inspection of the aircraft to determine damage. Finally, there were 186 cases of bird remains found by the airport authority with no report of a strike. For the cases of aircraft damage and remains found on the aircraft, the findings were individually displayed using Microsoft Excel. The date, type of aircraft, and area struck were noted.

Table 2
Bird Strike Data at the MKE Airport Classified Based on the PIREP Category for the Period from the 2013 to 2016

PIREP category	Year				Totals
	2013	2014	2015	2016	
PIREP - Negative Findings	13	10	9	7	39
PIREP - Only Remains Found	1	3	8	2	14
No PIREP - Only Remains Found	32	39	46	69	186
PIREP – Physical damage Seen	4	3	1	0	8
PIREP - Remains on aircraft No physical damage	1	10	2	9	22

PIREP - Remains found No damage to aircraft	7	9	7	5	28
Total bird strikes	58	74	73	92	

Analyses shows that for the observed sample of wildlife strikes the most common aircraft type is Boeing 737, followed by Airbus A310. This data needs to be taken with caution due to the fact that B737 and A310 are extremely popular aircraft types in civil aviation.

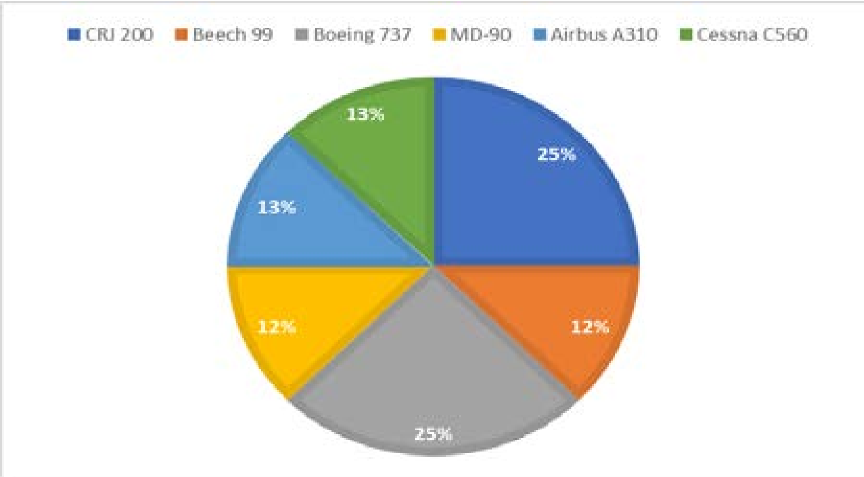

Fig. 5.
The Aircraft Type in Cases when Bird Strike at MKE Airport Caused Aircraft's Damage for the Period from the 2013 to 2016

4.1. PIREP - Physical Damage of the Aircraft has been Detected

In case of bird strike at the General Mitchell International airport following actions have been taken:

- Airport operations staff collects bird remains;
- Flight information and aircraft information is collected;
- If aircraft is at gate, it is inspected for damage;
- Pilots are interviewed;
- Any damage is photographed;
- All information need to be entered into logbook;
- Identifying location of strike on the airport's map;
- Discussing how strike happened based on pilot interview.

Wildlife-aircraft collision sometimes means collision with entire flock of birds in which aircraft would suffer multiple impacts. These cases are particularly dangerous because different parts of aircraft may be damaged and cause multiple failures. The most famous case of such kind is the flight 1549 when collision with flock of f Canada geese caused shut down of both engines. Consequently, the crew was forced to land at the surface of the Hudson river. Study of bird strike occurrences at MKE airport showed that windshield was the most vulnerable part of the aircraft (Fig. 6). This is expected due to exposed position of the windshield and the weaker material comparing to other parts of the aircraft.

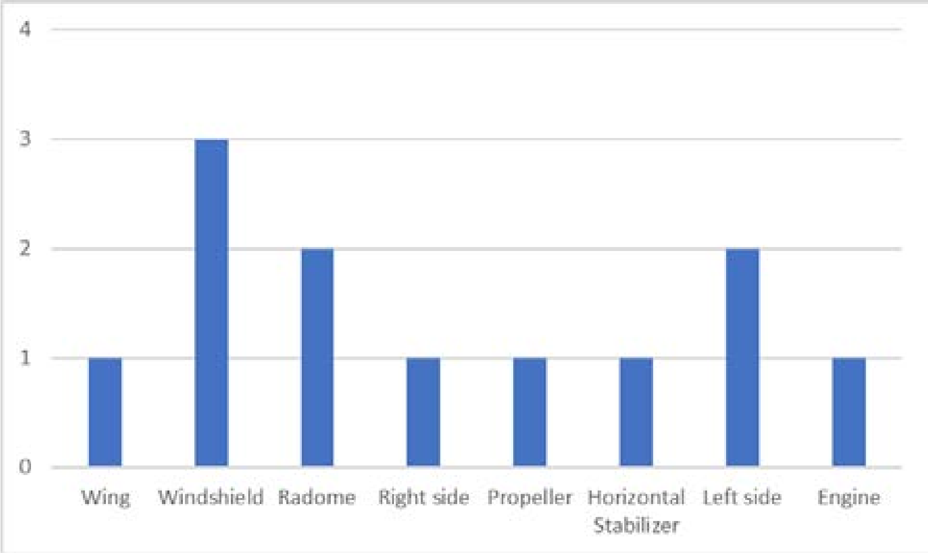

Fig. 6.
The Part of the Aircraft which Suffered the Damage after Bird Strike at MKE Airport for the Period from the 2013 to 2016

Wildlife strikes that caused aircraft damage for this dataset have been emphasized for each year for the period from the 2013 to 2016 (Fig.7).

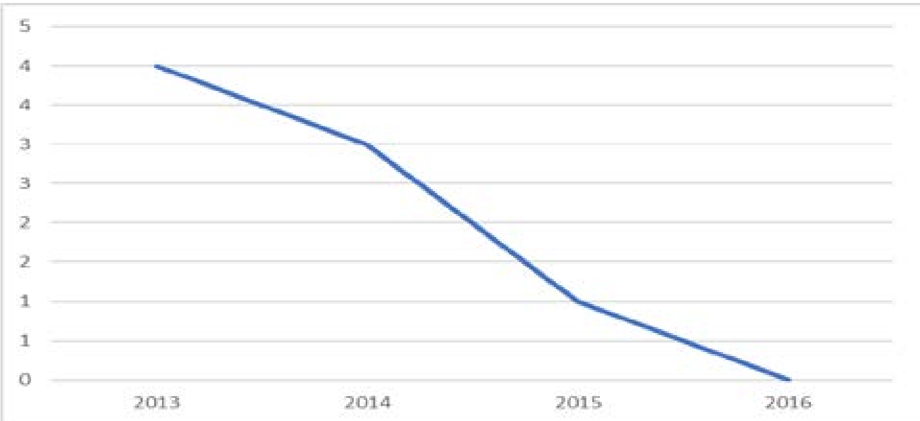

Fig. 7.
The Number of Bird Strikes that Cause the Aircraft's Damage at MKE Airport for the Period from the 2013 to 2016

4.2. PIREP - Remains on Aircraft have been Detected but without Physical Damage to the Aircraft

The study analyses wildlife strikes which caused the aircraft damage and the cases of strikes without damage separately. Per the above research methods, from January 1, 2013 to December 16, 2016 8 cases of bird strikes that caused the damage to the aircraft have been identified. In this chapter 22 cases of bird strike where residue was found on the aircraft but without a damage have been analyzed. For the second bird strike dataset same research methodology was used and the given results are displayed based on various criteria such as type of the aircraft that participated in the collision, part of the aircraft that suffered the impact, the number of bird strikes cases for specific dataset for each year in the given period.

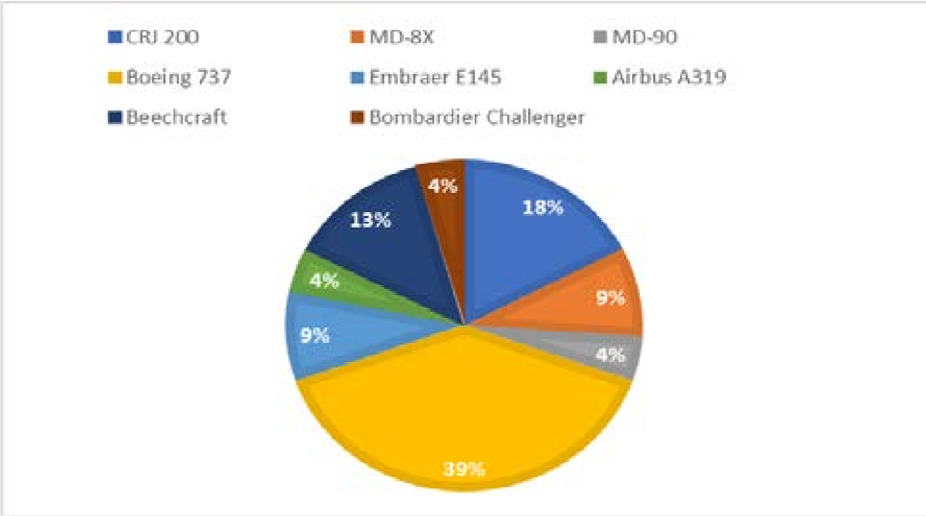

Fig. 8.
The Aircraft Type in Cases where After Bird Strike Remains were found on the Aircraft but Without Physical Damage, for the Period from the 2013 to 2016

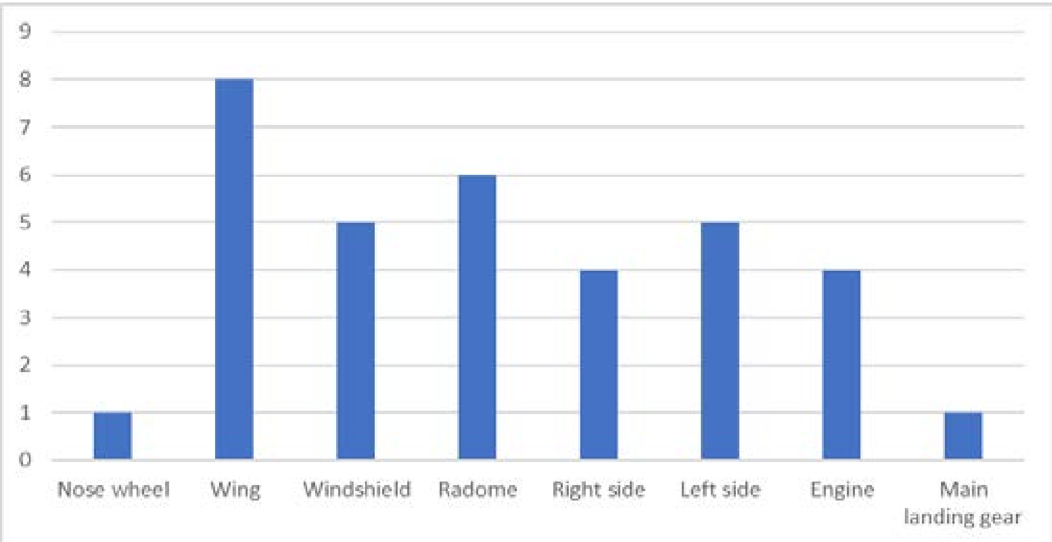

Fig. 9.
The Part of the Aircraft which Suffered the impact after Bird Strike at MKE Airport - Cases where Remains were Found on the Aircraft but without Physical Damage, for the Period from the 2013 to 2016

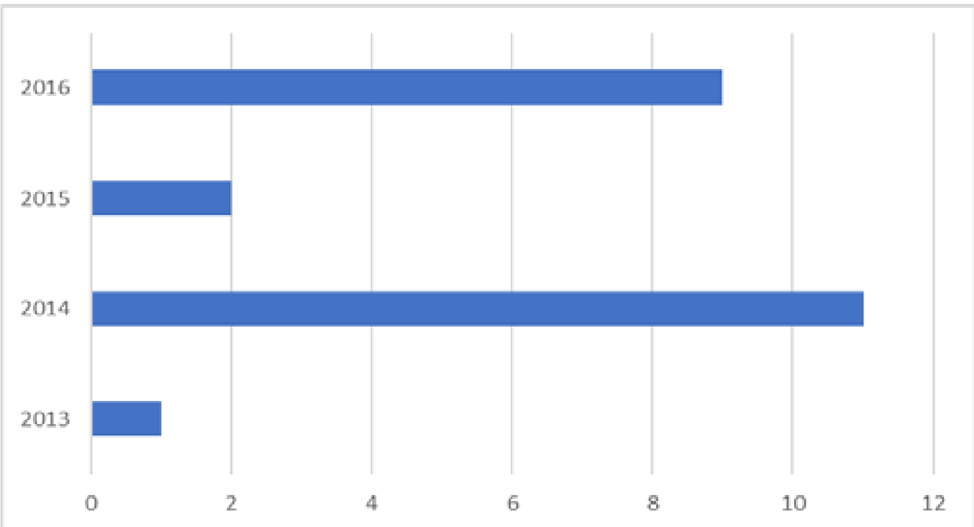

Fig. 10.
Yearly Distribution of Bird Strikes at MKE Airport for Cases when Remains were found on the Aircraft but without Physical Damage, for the Period from the 2013 to 2016

5. Conclusion

For the years 2008 to 2015, the 97 751 wildlife strikes were reported to ICAO by 91 States. Wildlife strikes are also affecting military aviation. At least 283 military aircraft from the 32 countries were destroyed or damaged beyond repair in 1950-99 as a result of bird strikes or during maneuvers to avoid birds. For the United States minimum number of military aircrafts that have been lost due to bird strike in this period is 62 (Richardson and West, 2000). Wildlife hazard concerns all parties in the aviation: airlines, airports, military organizations and aviation authorities. Complexity of the problematic requires comprehensive approach and constant improvement. First step is valid and detailed occurrences reporting. Failure to report bird intrusion leads to an underestimation of the true risk, while the false alarms may lead to blindfold management efforts (Ning and Chen, 2014). General Mitchell International airport operates in accordance with FAA regulations and recommendations regarding wildlife management. Closeness to the Lake Michigan and presence of 128th Wisconsin Air National Guard makes MKE airport more exposed to wildlife hazard. Collected wildlife strike data for the MKE airport showed bird strike data for each PIREP category. It is shown that the number of bird strikes that caused the aircraft's damage at MKE airport for the period from the 2013 to 2016 was constantly decreasing. Same trend hasn't been established when it comes to cases with detected residue but without physical damage.

MULTIAGENT MODELLING OF INDIVIDUAL TRANSPORT BEHAVIOUR IN THE OSTRAVA CITY

Roman Siwek[1], Jiří Horák[2]
[1,2] VŠB-Technical University of Ostrava, Department of Geoinformatics, 17.listopadu 15, Ostrava-Poruba, Czech Republic

Abstract: Current computational technologies enable to model transport conditions on the base of stochastic simulation of individual movements. This approach emphasizes a behavioural aspect in the modelling and recommendation to build models by aggregation from individual characteristics and needs. The aim of the paper is to present results of evaluation of individual car transport modelling in the Ostrava city using multiagent simulations (MAS) implemented in the AnyLogic software. The individual mobility patterns are derived from results of the questionnaire survey in Ostrava using the Day Recognition Method following age and gender structure. The residencies of agents are represented by 264 median centres of urban zones. Destinations are location of 2141 important employers, shops, and sport facilities. The random trips were generated according to expected temporal distribution of transport requests for 5 typical scenarios. The external OSM server implements car and pedestrian transport including Open Source Routing Machine (OSRM) for searching routes. Appropriate destinations are randomly selected according to the type of targets, their capacities, distances and the transport mode applying the gravity principle. AnyLogic implements the transport movements based on parameters delivered from the OSM server, visualizes and records all trips into a database log. Further statistical processing of data recorded from more than 0.5 million trips enables to evaluate the transport situation using indicators like average distances, time and the share of pedestrian mode. The results show relatively heterogeneous employer's accessibility with significant differences between urban centres and peripheries as well as strong variations in peripheries. It indicates important local differences in road network and employer's distribution. The results are useful to better understand commuter's needs, for targeted development of road infrastructure, for modelling traffic frequencies in each road segments and for predictive modelling of conditions after completion of the city road network.

Keywords: multiagent modelling, simulation, urban mobility, transport, commuting, Ostrava, AnyLogic.

1. Introduction

Current computational technologies enable to model transport conditions on the base of stochastic simulation of individual movements. This approach emphasizes a behavioural aspect in the modelling and recommendation to build models by aggregation from individual characteristics and needs.

Today data capture about human movement is technically simple using various individual sensors and tools of providers mainly communication and transport services. It includes GNSS logs for cars, bikes or persons (Liao et al. 2007, Kostak et al., 2017), cellphone aggregated CDR data (Yim, 2003; Tranos, Nijkamp, 2015), social networks and user-generated contents (Lee et al., 2013; Hawelka et al., 2014; Kocich, Horák, 2016), Wifi logs (Fratasi, Della Rosa, 2017; Krejcar, 2006), contactless cards in the public transport (Houée, Barbier, 2008) and different combinations (Brida et al., 2014). The common issues of such data are limited availability (limited in time and participants), cost, big data phenomena (Beyer, Laney 2012; Bello-Orgaz et al., 2016), missing reasoning and privacy protection binded with processing of individual personal movement and behaviour. Often such data describes only selected user's category (customers of only one provider, users of registered contactless cards and not all travellers etc.) which create a bias.

Contrary we can utilise a soft data obtained from i.e. questionnaires. The advantage is better understanding the behaviour of each respondent (if detail questions about the purpose, frequency, patterns and influences are included). Unfortunately, due to the privacy protection, lack of time and lack of willingness to provide details we usually obtain a rough picture of human movement patterns without precise time and distance measurements, accurate location of origins and destinations etc.

Disadvantages of both data groups (hard and soft data) can be overcome by joining these data (Klous et al., 2017; Kimijima, Nagai, 2017; Šveda, Madajová, 2015) and integrate them to models of human behaviour which reflects our existing knowledge. Such models can generate simulated artificial data which enable us to precisely answer our questions about movement conditions, to significantly improve our pattern analysis (González et al., 2008; Burian et al., 2018) and understanding the pulse of the city (Batty, 2010).

Such models can be developed in multiagent simulations (MAS). Simulation models based on MAS enable to solve problems and utilize tools depending on time, previous knowledge and also not clear relationships between model elements and their non-linear behaviour. The model retains the system states in loosely coupled autonomous systems called agents (Wooldridge, 2009). Agents in the modelling environment pose certain location which can be changed during modelling according to their properties (Benenson, Torrens, 2004). The agent often knows what his state is and its following activity depends on this state. MA models support simultaneous modelling for different levels of abstraction (Marceau, Benenson, 2011). It enables to represent individual persons as well as to provide aggregation of result for the whole class of agents, or all population of agents, or other logic entities.

Such models are well fitted and broadly utilised also for transport modelling like commuting to work or daily travel behaviour of population (Tilahun, Levinson 2013; Čertický et al., 2015).

[2] Corresponding author: jiri.horak@vsb.cz

The paper is organized as follows: first, the pilot city and data sources are explained. Further, AnyLogic SW is described with focus on GIS capabilities and how to utilize them for transport mobility modelling. A special chapter is dedicated to description of external services required for routing and target selection. Next, details about model implementation in AnyLogic are provided. The final chapter provides results of modelling and discuss the accessibility evaluation for residents.

2. Methodology

2.1. Pilot City

The Ostrava city (290 thousands of inhabitants, 214 km^2, fig.1) is characteristic by its heterogeneous and non-concentric urbanisation (Kovář, 2009; Igor et al., 2012), where densely urbanised settlements are separated by large non-residential parts like industrial and technological complexes (i.e.ArcelorMittal Ostrava, BorsodChem MCHZ), or by a coarse rural settlement, forest and agricultural fields, mining waste dumps etc.

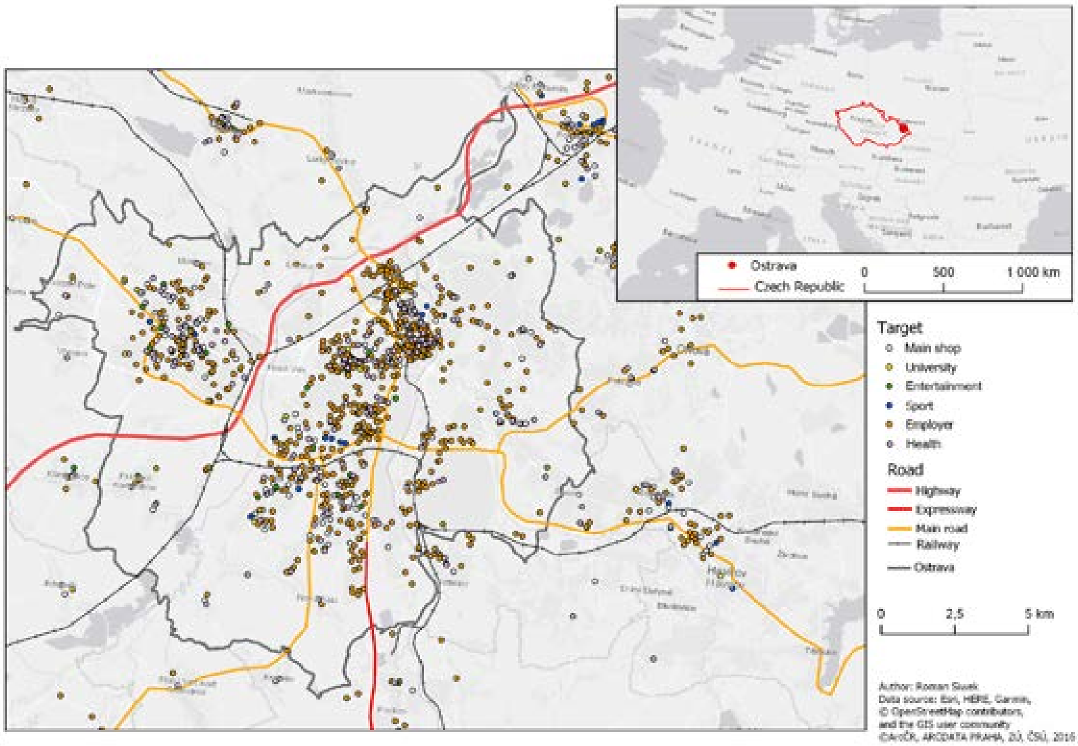

Fig. 1.
Pilot city
Source: own map

2.2. Type and Distribution of Activities

The individual person's mobility is modelled using the scenarios of activities which is planned to perform the given day. Our modelling is currently focused only to residents for whom the start from home and the return to home are anticipated. Each activity can be performed on different places. Different transport modes and their combination can be used for movements but currently in our simulations only car and pedestrian transport modes are available.
Type of activities, their frequencies, usual time and their chaining into the sequence of activities (the scenario), were derived from results of the questionnaire survey in Ostrava between September 22 and 26, 2014 using the Day Recognition Method following age, gender, economical status, educational and locational structure. Altogether 534 questionnaires were collected (Burian et al., 2018). The results document also type of targets, distance and time of travelling, used transport mode etc.
The modelling and its results are focused on the most frequent group of respondents which are full-time workers (employees). The distribution of probabilities of various scenarios for employee is summarised in fig. 2.
The **residencies** of agents are represented by 264 median centres of buildings in urban zones. Potential **destinations** are locations of 2141 employers, shops, educational, health and sport facilities (point features in fig. 1). Each destination is attributed by its capacity (estimated number of employees, shopping area etc.) and time restrictions (working hours, opening hours etc.) to identify time interval when the destination acts as a target.

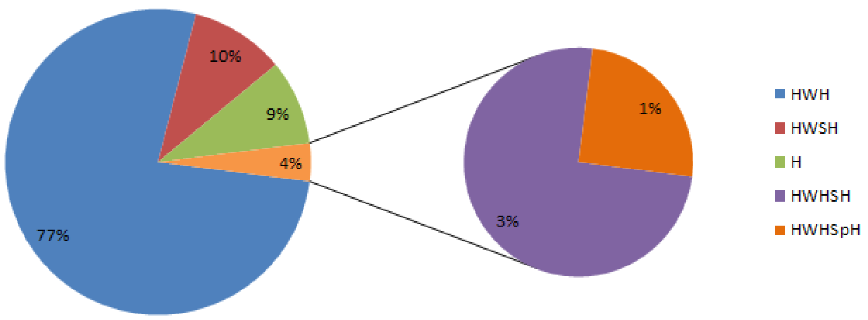

Fig. 2
Probability of scenarios for employee (H home, W work, S shopping, Sp sport)
Source: questionnaires in Ostrava, September 2014

2.3. AnyLogic

For model development the software AnyLogic version 7.3.5 was selected. AnyLogic is a simulation software enabling the design of various types of models like supply chain models, management and marketing, optimisation of manufacturing and storing complexes, including logistic chains and transportation (Grigoryev 2015, Janosikova et al., 2017). The software includes specific libraries for modelling different transport environment and mobility types like Rail Library, Pedestrian Library or Road Traffic Library.

Relatively new (since 7.0 version) (Churkov, Borshchev, 2015) are **GIS capabilities** in AnyLogic. The obligatory component for any GIS related model is the map window offering several map projections (e.g. Cartesian, Mercator).

There are several possibilities implementing agents' movement in this window. Movement functions play an important role for mobility modelling not only for visualisation. The first option is to mark out the whole route. The second option is to use Route Provider function which is more flexible. It enables agents to select own route based on communication with the external server. The type of transport and the corresponding algorithm have to be selected. It is possible to use own (map) server or the route optimisation is performed by AnyLogic based on imported data. Testing of both possibilities discovered issues of the second variant in the case of large data volume (even the graph calculation was failed for the countrywide road networks). Thus we decided to use external map server to provide routing.

2.4.External Services for Agents

The model anticipates a rational choice of the transport mode between car and pedestrian transports. Thus it is necessary to provide parallel route optimisation for car and pedestrian modes to select the favourite mode according to results. For both cases the external Open Source Routing Machine (OSRM) for fast graph searching in road or other networks was utilised. The important step for installation is the selection of the appropriate profile for the network. The profile is a script written in LUA language which describes various network situations. It comprises also information about appropriate setting of values for edges and nodes in the graph, mainly average velocities for each type of road, identification of one-way roads, quantified preferences for every type of roads, penalty for turning and for delay on lights. The script is used to create the graph and not for every searching of the path. Three standard profiles (cars, walking and biking) are available but it is possible to create your own profile (GitHub 2017).

2.5. Model Implementation

AnyLogic performs the transport movements based on parameters delivered from the OSRM server, visualizes routes and records all trips into a database log.

Three classes of agents are implemented: Employee, Destination, and Home. The obligatory backend element of any AnyLogic model is the **Modelling time** where the time unit (one minute in our model) has to be set up. The Modelling time launches all triggers for scenario selection which are regularly repeated at the beginning of the new day. It is also utilised for the selection of destinations or selection of temporal duration of activities.

The **Destination** and **Home** are created from database records by the script in the Main agent before the start of modelling.

The required number of **Employee Agents** is generated during the creation of Home Agents representing population of employees in the given urban zone. They obtain appropriate attributes as parameters; some of them are generated by probability functions.

The behaviour of the Human Agents is driven by scenarios and the agent selects every day only one of the possible scenario for execution. The scenarios were constructed on the base of the survey results – frequency of various activities and their sequences master the probability of scenario implementation.

The model implementation of scenarios contains definitions of various agent's state, the transitions between them, and decision taking i.e. which target and optimal transport mode to select.

Scenarios consist of various states of agents in disjunctive branches of the model (fig. 3). Every scenario possess certain probability of implementation (derived from the survey results) transformed into the corresponding interval of values from uniform distribution from which a random selection is made.
The starting time and duration time are also randomly selected from the probability distribution based on travel diaries. The similar approach is applied to decide when to leave the activity – after randomly selected duration from the probability distribution of duration from the diaries of the corresponding group of respondents.
The decision nodes, placed between each two following states, assure the model's stability and provide the possibility to return the agent home what is necessary in cases when no target for following activity is available. It may happen especially due to time restrictions applied on targets when no „open" targets is available for the given activity in the requested time.
Every scenario ends returning the agent home. The current selection is one of five scenarios (fig. 3). One of them is to stay at home (due to i.e. home office, sick day, and holiday). Scenarios of HWHSH and HWHSpH share the same beginning and they are not fully separated in the diagram.

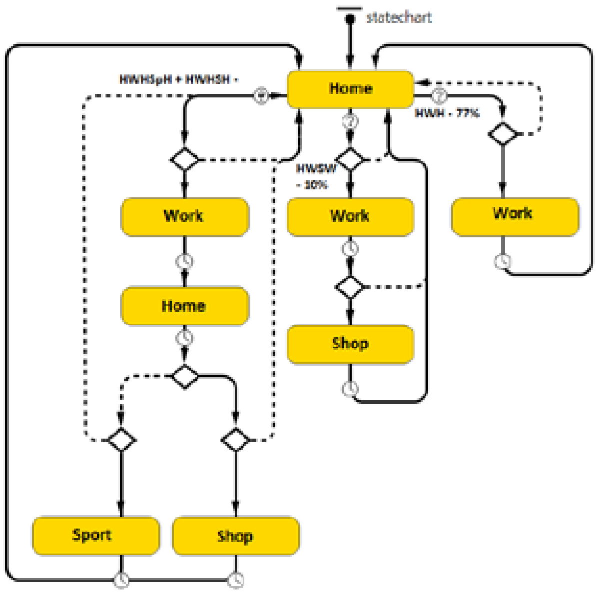

Fig. 3.
Diagram of possible scenarios for Employee Agents in AnyLogic
Source: own scheme

The target for the given activity is selected when the Modellin time matches the time simulated for this activity. The appropriate target is randomly selected according to the type of target, its capacity, distance and the transport mode applying the gravity principle (Horák et al. 2014). The gravity values are calculated for all considered transport mode and all relevant "open" targets. This calculation takes into account also personal preferences of the agent (currently economic type, age, education) and the weight of the target (expressed usually by some capacity assessment like number of employees, shopping area etc.). Higher gravity value indicates better transport mode for the given target. Values are recorded with the transport mode for all relevant targets. Finally the gravity values are normalised, ordered and used for the proportional selection of the target. It means the target with the highest gravity value is not always selected but the normalised gravity value is used as a probability of the target selection to be the goal.
Further, for the selected target (goal) the travel distance and travel time for better transport mode from OSRM server are found. Next, the agent is moved from the origin to the destination along the route provided by the Route Provider for the given transport mode and using the time delivered by the OSRM server.
The model was used for the **accessibility evaluation for employees**. To reach the balanced evaluation we use the same number of simulations in each urban zone. The model launches 10 agents in every urban zone every day and repeat simulations for 50 days, thus we collected 500 simulations for every urban zone. Further statistical processing of data recorded from more than 0.5 million random trips enables to evaluate the transport situation using indicators like average distances, time and the share of pedestrian mode.

3. Results and Discussion

The evaluation of accessibility based on results of the multiple agent simulations utilises selected parameters of the executed movements. We have focused on the share of the pedestrian mode (the rate between the usage of pedestrian and car modes), transport time and transport distance which were calculated as an average from all individual trips.
The first obligatory step is to exclude records of not completed executed scenarios. The ratio of prematurely terminated scenarios represents also one of the useful indicators of accessibility.

The modal split (fig. 4) shows the places where employers (and shops and sport facilities) are accessible on such high level that pedestrian mode is significantly utilised. It corresponds to the premise of higher walking in the centre (Haybatollahi et al., 2015). Except of the centre, such places are located in Poruba (western part), in the southern part of the city and in the surroundings of the ArcelorMittal Ostrava (SE). In these places the destinations are very well accessible and possess the highest evaluation.

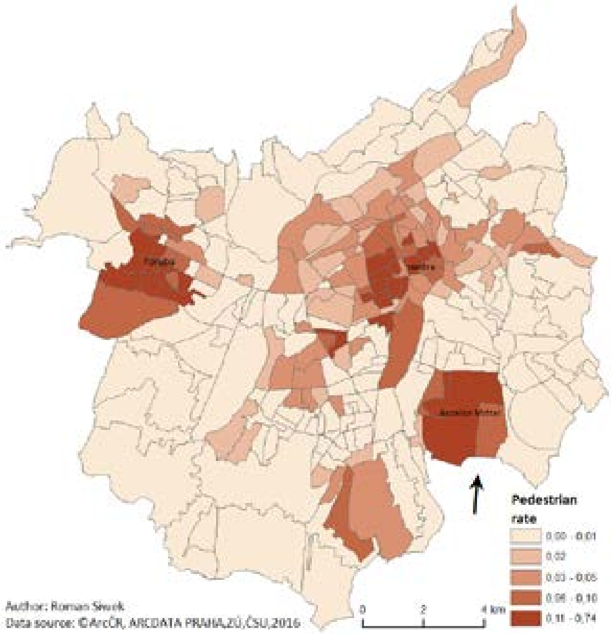

Fig. 4.
The average share of the pedestrian mode from all agent movements
Source: own calculation

The next figure (fig. 5) shows similar inverse patterns. The average travel distances are the smallest in Poruba and the city centre and it shows good accessibility for these centres of population. To the opposite the third most inhabited centre, Ostrava-south, clearly shows worse conditions mainly due to the shortage of large employers in this city part. The second important observation is the pattern is more continual than those for pedestrian share. It indicates relatively sharp switching between usage of pedestrian and car modes and a potential to relax this condition to better reflect differences in individual preferences for pedestrian/car mode. High average distances point out places with bad accessibility conditions. Some of them is relatively close (measured by the Euclidean distance) to places with minimal distances (Hošťálkovice, Lhotka, Paseky near Bartovice etc.). Such abnormal increase of average distance is usually caused by geographical barriers issued in high deviality of routes. While Hošťálkovice and Lhotka are separated from the rest of Ostrava by Odra and Opava rivers, Paseky lies in the shadow of the large fenced industrial area of AccelorMittal.

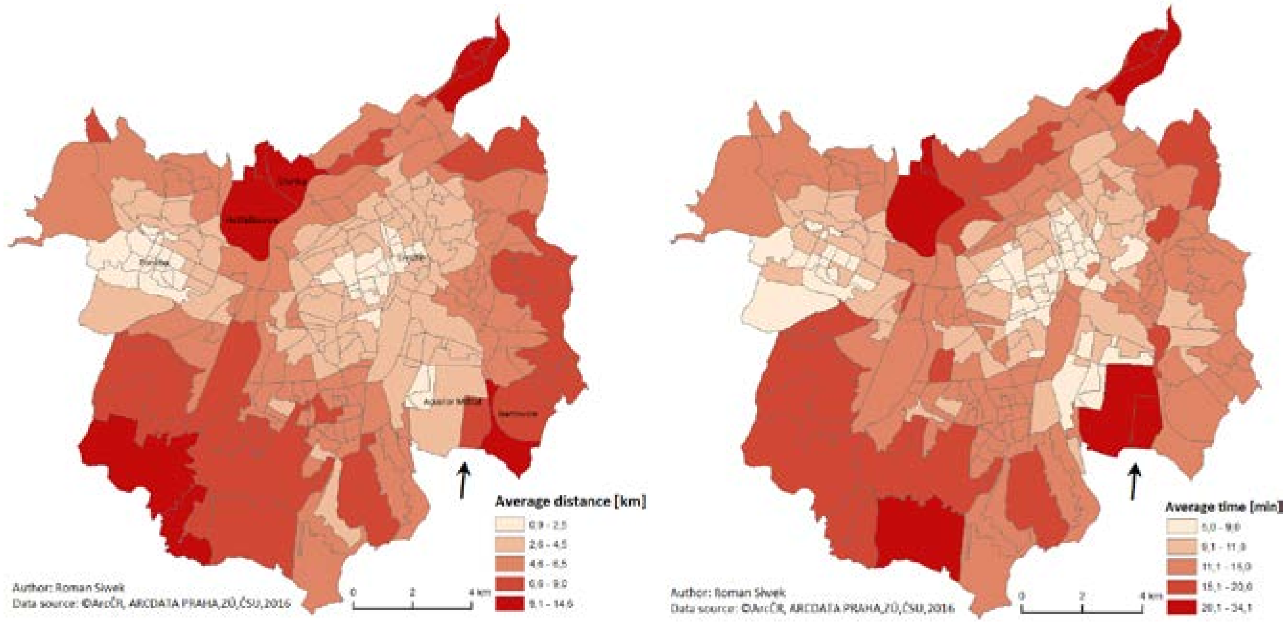

Fig. 5.

Average distances (left) and average travel time (right) of all movements of Employee Agents using car or pedestrian modes
Source: own calculation

The next figure (fig. 5 right) portrays the average travel time. Comparing with the left figure we can see some differences. More fragmented and less continual central parts of settlements shows the internal differences of accessibility caused by the different street/road infrastructure. Some urban zones in SW and SE indicate relatively well temporal accessibility despite of larger average distances. The reason is better developed road infrastructure in the southern part of the city which enables quick movements even for longer distances.
In fig. 6 we can see a bivariate choropleth map where the mean and variability can be study together. It is clear that some urban zones with low average movements are burden with high variation of the accessibility (blue colours in the figure) which are well assessed only for limited number of destinations. The worst conditions are coloured by dark red – in such places (Polanka, outer part of Radvanice on E) practically all movements are very long and the resident has no choice to shorten it. The pink violet shade is quite frequent in the territory, mainly for marginal parts, and it indicates urban zones with large but variable distances which give an opportunity to satisfy the part of requirements in short distances.

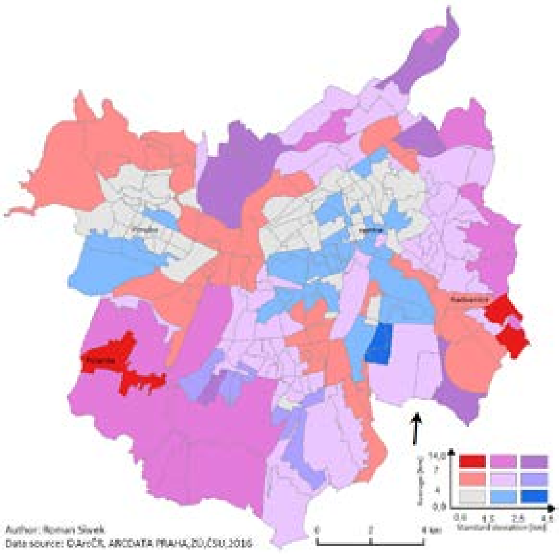

Fig. 6.
Bivariate choropleth maps of the mean and standard deviation for distances of agent's movements
Source: own calculation

4. Conclusion

The MAS was developed using the most frequent scenarios, probability distribution and gravity modelling based on travel diaries. MAS utilizes external OSRM servers which provide car and pedestrian network services including optimal routing and cost evaluation.
The results show relatively heterogeneous employer's accessibility with significant differences between urban centres and peripheries as well as strong variations in peripheries. It indicates important local differences in road network and employer's distribution. The results are useful to better understand commuter's needs, for targeted development of road infrastructure, for modelling traffic frequencies in each road segments and for predictive modelling of conditions after changes in the city road network.
The accessibility evaluation is not the only possibility how to utilise such simulations. We can model the dynamic population in arbitrary spatial and temporal steps (to aggregate locations of agents by i.e. one-minute interval) and create series of kernel density estimations of expected dynamic population during the day. Such results are valuable to identify accumulation of travellers and provide reasoning of existing congestions, to model loading of any parts of road/street network or for predictive modelling of traffic distribution in the case of road network planned changes. Except of transport application also other domains like emergency planning and risk management would utilise modelling the dynamic population in the territory to plan appropriate measures.
The weak point of these models is their validation. We have no appropriate data to validate results of the modelling. We intend to use the remotely sensed data (including hyperspectral data) to detect cars and compare the modelling results with real intensities on roads. In future we plan to implement also an external server for the public transport mode to cover all significant transport modes.

INTERMODAL AIR-RAIL TRIPS - BAGGAGE DROP OF INSIDE THE TRAIN

Bernhard Rüger[1], Christian Albl[2]
[1] *Vienna University of Technology & St.Pölten University of Applied Sciences, Austria*
[2] *ÖBB, Austria*

Abstract: Supported through the increasingly extended high-speed railway network in Europe, there are a wide range of considerations for replacing intra-European air traffic to a large extent with the railway. In short-haul traffic, the railway can thereby replace the whole of air traffic as well as play an essential role in feeder traffic on medium- and long-haul flights. In order to create a corresponding demand, the railway must be highly attractive and operate within the framework of an overall airport-feeder system. The following essay deals, from the point of view of travellers, with the basics that should produce a corresponding attractiveness and thus acceptance.

Keywords: AIRail cooperation, intermodal transport, baggage handling.

1. Introduction

In order to reach the EU international community of nations demand for a limitation in temperature rise by 2050 in the EU, greenhouse gas emissions in the transport sector must be lowered by at least 60% compared with 1990 and around 70% compared with 2008. By 2030 a reduction of about 20% below the level of 2008 is required.1 Taking into account the assumption that mobility will continue to increase and as a result the volume of traffic will increase, a reduction in greenhouse gases can only be achieved by an increased use of environmental- and resource-conserving modes of transport. For this purpose, the European Commission has defined ten objectives for the transport sector in a White Paper titled "Roadmap to a Single European Transport Area - Towards a Competitively Oriented and Resource-Conserving Transport System". One of these objectives targets long-haul passenger traffic and proposes the following measures:

- Completion of a European high-speed railway network by 2050;
- Tripling the length of the existing network by 2030 and maintenance of a dense rail network in all member states;
- By 2050 the majority of passenger transport over middle distances should be allotted to the railway.

In order to be able to meet these objectives as much as possible, one feasible approach is to shift to the train (ultra) short-haul flights, which usually have a feeder function to medium- and long-haul flights. In this regard, there are a variety of cooperation possibilities between the aviation and railway sectors.

Parallel to this, the political objectives in the field of air traffic are formulated in “FlightPath 2050” published by the European Commission in 2011.3 In this strategy paper, in addition to societal objectives (for 90% of EU citizens a door-to-door four hour connection should be possible by 2050), environmental protection measures are also formulated (reduction of emissions despite projected growth in the aviation industry). This is a subject of discussion by European industrial leadership who also demand preservation of the already very high safety level in Europe despite the increase in air traffic. These objectives are currently being processed and implemented within the framework of European research programmes (such as JTI CleanSky - fuel efficiency and noise reduction and SESAR - "common" European airspace)

2. Intermodal Cooperation Concepts Between Train and Aircraft

A good transport connection is an important attractive feature for airports. At present, around 130 of all airports worldwide have rail connections, with further railway connections being planned. Originally, rail connection played only a limited role, which mostly involved only local transport and primarily connected city centres and the surrounding areas with airports. It has only been in the past few years that concepts have been implemented to connect city centres to airports, which have made rapid connections possible (e.g. Heathrow Express in London), and in some cases also connections providing service functions such as check-in or luggage check-in (e.g. the CAT in Vienna).

With the advent of high-speed rail transport, new opportunities for trains were created with regard to their competitive relationship to aircraft. The shorter travel times allowed the train to compete directly with aircraft at distances between 350 km and 750 km. From this competition situation, cooperation comprised of a combined offer between train and aircraft also developed to some extent. A distinction is made in the literature between the following forms of the relationship between train and aircraft:

2.1. Competition, Cooperation and Integration

[1] Corresponding author: Bernhard.rueger@tuwien.ac.at & Bernhard.rueger@fhstp.ac.at

The two points "cooperation" and "integration" are the forms of intermodal traffic between train and aircraft which are relevant for airport connections. Different forms of cooperation between railway companies (RCs) and airlines are being developed, which are intended to provide passenger-aligned services. This can include, for example, the area of luggage transport, check-in, ticketing, information and security services. Depending on the degree of cooperation, the offers may be classified as follows:

- **low:** This type of cooperation is intended to provide travellers with a fast and congestion-free arrival to or departure from the airport. This includes, for example, the sale of train tickets by the airline (e.g. Rail&Fly - Germany).
- **moderate:** This form of integration usually involves codeshare agreements between the RC and the airline. In addition to the train number, the respective train is assigned its own flight number and is distributed by both parties. The advantage for the traveller is that in case of late arrivals, the necessary measures such as rebooking are carried out by the airline or the RC (e.g. tgvair - France).
- **high:** A higher form of integration in addition to the aforementioned points also includes luggage transport or separate areas in the train for business- and first-class passengers (e.g. AIRail - Germany, up to 2007).

Table 1

Measuring results provides an overview of the forms of cooperation and the respective characteristics

Level of cooperation	Type	Example	Participating companies	Range of services
low	Interlining-agreement	Rail&Fly	DB with 70+ airlines on 5000+ routes	Sale of tickets
moderate	Codeshare-agreement	tgvair	SNCF with 10+ airlines	Assignment of own train- and flight number; ev. Integration of IT-systems
high	Joint-Venture	AIRail	Lufthansa with DB between Frankfurt – Cologne and Frankfurt - Stuttgart	Coordination of luggage transport (up to 2007) and other service features; separate areas and catering service in the train

There are different cooperation models between airline and railway operators worldwide. In the following, four concrete examples are described in more detail, each of which have a different degree of cooperation.

Table 2

A comparison of the included service features of the described models

Intermodal offer	Train ticket sales by airlines	Codeshare - agreement (own flight number for train)	Check-in at departure train station	Luggage check-in at departure train station	Guarantee in case of late arrival	Separate area in the train and catering
Rail&Fly (DB)	●					
Fly Rail Baggage und Check-in at the train station (SBB)			●	●		
tgvair (SNCF)		●	●*		●	
AIRail (DB)		●	●	○**	●	●

*Note: *just for a view airlines; **service was offered till 2007.*

3. Influence of Luggage on the Choice of Transport Mode

The transport of luggage is an essential decision-making criterion for the choice of transport mode. Despite increasing costs in the area of motor vehicle traffic or increasing traffic problems, the auto still enjoys unwavering popularity, with feeder traffic to the airport as well, above all due to luggage transport when travelling. The reason is that compared to all other elasticities, elasticity with luggage is highly valued (see Table 3).

Table 3

Travel elasticity in Austrian holiday travel traffic – comparison

Luggage	0.685
Mobility to destination	0.655
Travel cost	0.630
Transfer	0.469
Travel time	0.386

Source: (Rüger, 2005)

The thereto by comparison lower cost and travel time elasticity presupposes that changes in travel cost whether these are: cost increases for passenger-car traffic, cost reductions for train traffic as well as alterations in travel time, prolongation with passenger-car traffic or expediting measures with public transport; in all cases of travel in which luggage is transported, these have a correspondingly lower effect than measures relating to luggage transport.
Thus, for example, for 82% of winter holidaymakers travelling by auto in Austria, travel luggage is a major reason for the choice of the auto during holiday travel, whereas for only 55% the cost and for 40% the travel time have a decisive influence.24 These findings apply analogously in feeder traffic to airports.
In the case of air travel, the luggage for example, strongly influences the choice of transport mode for arrival at the airport. Above all in the case of transport of larger and heavier pieces of luggage, airport taxi services or private autos are chosen depending on the distance to the airport. The train is then preferred if little or no luggage is taken. Conversely, travellers in intermodal traffic (rail- air-traffic) are prepared to pay the most for luggage transport services compared to all other services.

4. Wishes for Airport Feeder Trains

In the research projects “Gepäcklos” and "TerminalAufSchiene", among other things, the wishes and needs of AlRail passengers for appropriate feeder trains were compiled separately.

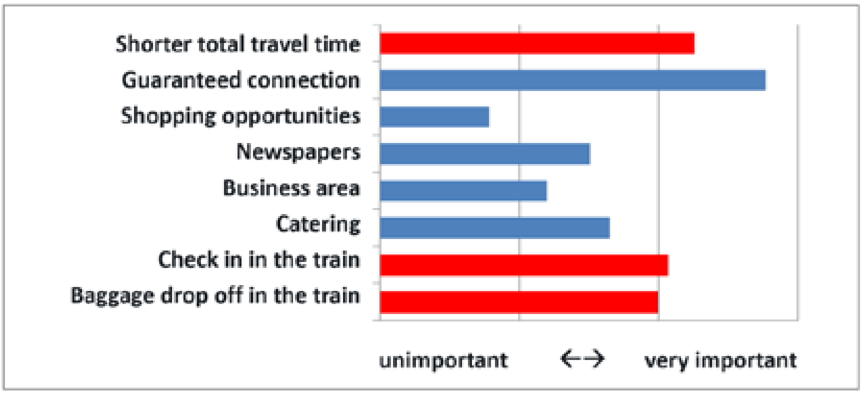

Fig. 1.
Importance of diverse product features for airport feeder trains
Source: (Albl, 2015)

In addition to the connection guarantee in the sense of assurance of connections or travel alternatives, which are offered in the above-mentioned cooperation and integration systems, above all the factors: "short travel time", "check-in on the train" and "luggage check-in on the train" play an important role in regard to the attractiveness and increased choice of the train in feeder traffic to airports. All three criteria are evaluated on average as "rather important", with an average score of 2.9 to 3.3 on a scale from 1 (not important) to 4 (very important) (see Figure 1) (Albl, 2015).
For approx. 70% of travellers arriving at the airport, the possibilities for handing over luggage and at the same time checking in on the train are important (for 40% of them even "very" important) and would therefore be a significant reason for the decision to choose the train as a mode of transport to the airport. For over 80% of travellers the shorter travel time is correspondingly important (see Figure 2).

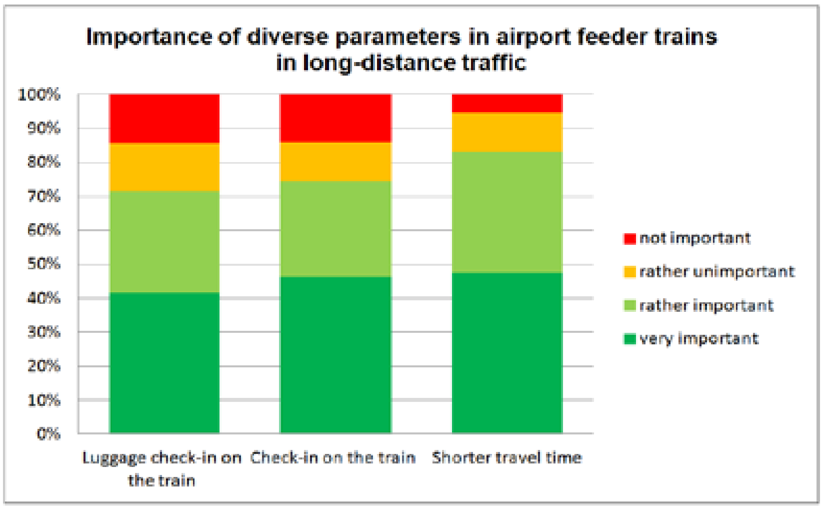

Fig. 2.
Importance of luggage drop off and check-in on the train
Source: (Albl, 2015)

For a short travel time, in addition to high travel speed and short stop-over time, an efficiently used travel time is also important. This can be achieved by relocating activities at the airport (e.g. check-in and luggage check-in) to the train. For this, an appropriate interior design in an airport feeder train is necessary. With regard to check-in service, it must be taken into account that through the use of new media, the classic check-in at the counter is being increasingly replaced by web check-in or mobile check-in. It is to be assumed that check-in at the counter is predominantly used in connection with luggage check-in. However, the possibility of check-in on the train is rated as similarly important to the possibility of luggage check-in on the train.

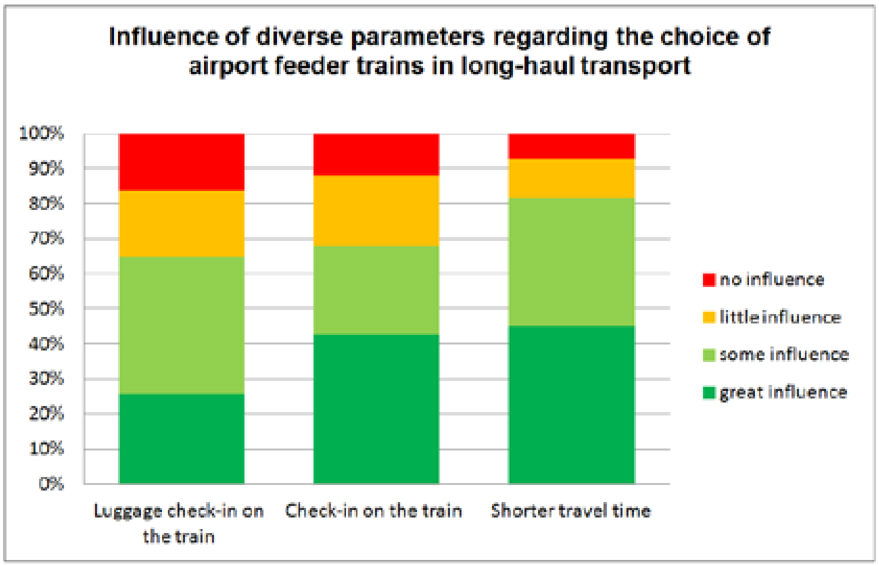

Fig. 3.
Influence of diverse criteria on the choice of transport mode for airport feeder traffic
Source: (Albl, 2015)

Regarding the influencing criteria: whether in the future appropriate airport feeder trains in long-haul transport will be chosen, 65% of travellers indicate that the possibility of luggage check-in on the train would have an influence on behaviour in the choice of transport mode. For more than 25% this possibility would have a great influence. In terms of travel time, over 80% of travellers say that a shorter travel time would have an influence on the future choice of the transport mode for arrival to flights and for 45% travel time for arrival would have a large influence (see Figure 3). It is important to take into account that travel time for arrival is not the only travel time to the airport, but is to be considered as a whole-time requirement for door-to-door mobility.

5. Conclusion

The studies show that there is a great interest among air travellers in using the train for arrival to the airport. Attractive service features tailored to air travellers are essential for the acceptance of the train. These include: on the one hand,

already known services and in many cases services that have already been implemented by many providers in the area of "connection guarantees". On the other hand, it is clear that above all luggage transport has a major influence on the choice of the transport mode, also in terms of airport arrival behaviour. In this area, there are to date few or no suitable service concepts that ensure the attractiveness of the train to a sufficient degree. At the same time, it is clear that from today's point of view, effective innovative concepts such as luggage check-in during train travel to the airport would create corresponding interest and acceptance by air travellers and would have a deciding influence on the choice of transport mode.
If the aim is to transfer a large part of intra-European short-haul air-feeder traffic as well as the airport-feeder traffic overall to the train, it is essential to develop innovative service concepts that are from the traveller's point of view, highly attractive and go beyond what is offered today.

Abstract: Reliability, speed and accuracy of transport according to customer needs is an essential aspect that affects the competitiveness of rail freight transportation. All resources used for planning, assuring and realization of individual transport are limited. The basis is that all operations must be planned, because it is the best way, how to provide service as required by customers with the least possible use of the capacity of the resources and also does not overload them. This paper considers the problem of improving short-term train path planning and operation path management that the ad hoc assignment of train path to the definite trainset operating under real-time information and automated assigning system. The proposed instrument performs dynamic assignment of ad hoc request for train running to appropriate train path through a fast and efficient solution procedure based on the assigning algorithm. The instrument reduce time for path assignment and enable to dispatchers use more time on solving real-time operational problems caused by disruptions. The procedure has been tested on real-life data from one of the major railroads in Central Europe.

Keywords: rail freight transport, planning, path assignment, train operating company, infrastructure manager.

1. Introduction

Railway transport is a dynamic system. The train operating company (TOC) must fill the conditions on the goods transport market. On the other hand, the TOC must satisfy the customers demand as much as possible. Creation of the train path is based on the customer requirements.

Unfortunately, the assignation of train path is an elemental limitation in the planning of freight train running. This is done by the fact that train path creation and assignment is not in the TOC competence, but infrastructure manager. Moreover, there is a long-term plan of assigned capacities of train paths being created one year before the timetable regular construction. This plan is needed to be abided as much as possible, because the train paths were already paid by TOC. There is a high potential of risk for TOC, that it won´t be possible to get another train path (the ad hoc train path) due to quality reasons or no capacity available. Last but not least the ad hoc train paths are more expensive than regularly constructed train path, what affects the final price.

This document is focused on problem of ad hoc straight unit trains. In the past, this problem was not being solved much, for example due to prioritizing of operational problems with the shipments. Customer´s requirements is not always possible to provide by trains from the regular timetable or train formation diagram. There are various influencing factors, like for example the arrival of the ship, technology of production, etc. Some of shipments are organized only few times per year, so it´s not possible to create the train path in regular construction for them. Also there are shipments, which are being organized without future plan, so it´s impossible to predict the real organization time. In some destinations, there is not possible to create the paths for regular timetable construction due to loss of orders, what again causes increased demand for ad-hoc paths.

As already mentioned, the current trend is customer oriented behaviour, where the train path plan is being adjusted based on the customer wish. There is a risk, that if the train paths were ordered as regular ones, it might cause sanctions for operator due to non-used/refused capacity, or wasting of the other capacities. All the cases of transport demand, which is not possible to be solved by regular trains, are planned ad hoc, as mentioned below:

- Unit trains, not mentioned in regular timetable;
- Unit trains, mentioned in regular timetable, with ride planned per demand;
- Late regular trains;
- Trains, which are operating delivery of shipments above the regular timetable and train formation diagram. (Internal document ČD Cargo, 2013).

In first and last mentioned case, the planning process works like below. First, client has to create order of transport, resp. ad hoc train. This kind of order client has to send current time before the estimated/demanded departure of train. After that order is being handled via system for long-term trace planning. If it´s not possible to handle the ad hoc order in the current scope, the order is returned back to the client and he is offered another operative solution. The order of ad hoc train has to include the starting and final destination details, sender and final recipient data, information about all transport operators, who will handle the shipment, borders crossing stations of the path, also information about length and weight of the train, goods, estimated time of handing/departure/arrival of shipment and moreover important

[1] Corresponding author: st34969@student.upce.cz

characteristics about shipment (for example dangerous goods). Ad hoc trains are being aligned in order of importance after the regular trains (Internal document ČD Cargo, 2013).
The aim of this document is to find the algorithm for ad hoc path assignation. The algorithm will be used in the operational planning for satisfying of customer demands or internal parts of TOC's.
Every train, which is not using the year regular timetable or any other timetable, is ad hoc train. A train which for example is using another timetable is a regular train whose timetable is scheduled 14 days before the drive, and in this period there is no other change of the timetable or planned capacities.

2. Problem Definition

The rail cargo operator, who provides wide network of current wagon load and also unit trains, which are connected via system, has in the environment of liberalised market take care about ordering of train paths and their using. In time of renaissance of rail transport is not possible to apply process, used in the past, when ad hoc trains were being handled only by experience and knowledge of dispatchers. It is necessary to find systematic and efficient solution for using of ordered, but useless paths. It is necessary to minimize infrastructure costs for TOC.

3. Analysis of Railway Infrastructure Charge

The railway infrastructure managers must deal with several factors that affect the assignment of the train route capacity. Those factors are:

- overload of the key infrastructure segments;
- global increasing amount of trains in the whole system;
- growing amount of passenger trains in the peak times;
- decreasing stability of the rail transport sector;
- increasing length of the transport lines, which causes higher variance of train paths;
- requirement for a more precise cost division of the provided services.

Some railway infrastructure managers have decided to change the system for calculating the transport infrastructure using cost. They have also decided to introduce a system with incentives and sanctions for regular using, or not using of the ordered services. (SŽDC, 2016) Those steps have a direct impact on the TOC's. The cost of the train running in the Czech Republic contains two basic parts. The calculation formula is:

$$C_c = C_{pk} + C_{pd} \tag{1}$$

Cpk is a cost of assignment of capacity (train paths assignment);
Cpd is a cost of using the infrastructure.

The price of assignment of capacity is calculated by the formula:

$$C_{pk} = K_1 + K_2 \cdot L + K_3 \cdot D \tag{2}$$

K_1 is a price of proceeding and assigning of train path and assigning of infrastructure capacity;
K_2 is a price of train route compilation;
K_3 is a price related with the day of assignment of train path;
L is a length of train path;
D is an amount of days which the train path is assigned.

The price depends on the submission time of the application, resp. on the length of time between the submission and the time of the train running. Despite the fact, that the core of this paper are ad hoc trains, it is necessary to calculate with non-used train paths planned regularly. (SŽDC, 2016) It is no doubt that is a necessary solve all tree infrastructure tariff parts.
The second part is a price of using railway network. The price Cpd is calculated:

$$C_{pd} = L \cdot Z \cdot K \cdot P_X \cdot S_1 \cdot S_2 \tag{3}$$

Cpd is a cost of using the infrastructure;
L is a length of train path;
Z is basic price;
K is coefficient of the railway line category of the (regional, mainline);
Px is product factor (train categories);
S1 and S2 are specific factors (weight, ETCS (European Train Control System) equipped vehicle);
In case of S2 factor fulfilling by the train, the carrier gets 10 % discount from the Cpd.

If the train path will not be used, the infrastructure manager charge penalty for non-usage. This penalty is charged by the formula:

$$F = T \cdot L \tag{4}$$

F is penalty for non-used infrastructure;
T is a sanction index (the level on this sanction is depend on the individual line and their using);
Larger TOC uses planning tool for planning and ordering of train paths use. This system usually allows to edit own train paths, modelling of the train runs and impact of modelled steps (Oltis Group, 2017d);
In the process of train path planning is necessary to use data stored in databases – for example data about infrastructure, another trains, lockouts, goods flows, locomotives, etc. Thanks to the link in the system is possible to deal with every feature. The results can be tested immediately. The program can calculate financial cost deviations from proposed technology (Oltis Group, 2017b).

Table 1
Inputs and Outputs of the information system for freight train operating company

Inputs	Outputs
Data about railway network	Freight transport timetable
Data about trains and locomotives	Matrix of relation for train formation
Archive data about goods flows	Data for managing of marshalling yards
Lockout plans	Plan of the freight trains composition
	The lockout orders
	Orders for the Infrastructure Manager System

Source: Authors with (Oltis Group, 2017b)

In context of the operational work planning for unit trains, the result are trains paths. These train paths are edited by the capability of the transport infrastructure capacity. The infrastructure capacity is ordered by the infrastructure manager system. (Oltis Group, 2017d) The result is complex background data from rail timetable for other systems used by another TOC's and infrastructure manager.
System approach methods and logic methods (analysis and synthesis) have been used for fulfilling the main objective of the paper. System approach in management tries to achieve application of functional analysis concept and application of general systems theory in management. It is characterized by complex view of objective reality that is assessed as a multi-dimensional organized unit. The contribution of this approach is based on inner relations management system analysis, in acceptance of importance of both mutual influences of inner factors and interaction of the system with its environment. (Habr, 1972)

4. Discussion

In this chapter algorithm **for assigning the train path to the railway infrastructure** is described. This algorithm chooses the most appropriate path between available paths (ordered paths in regular timetable) or between available paths and ad hoc (new) path. The algorithm could be used in the short time planning and operative control of train running. The algorithm completes the totally missing element in the planning of freight railway transport and assignment (and management) of infrastructure capacity (especially in the Czech Republic).
The input data for algorithm are:

- ordered paths of individual freight trains;
- time possibilities of available train drivers, their work plan;
- available path offered by the infrastructure manager;
- routing of freight wagons;
- customer´s demand.

In the everyday railway traffic, the algorithm has to be connected with usually used information systems for TOC's and infrastructure manager. During the test, done by authors, the algorithm worked with sample data.
During the whole process of checking capacity of railway infrastructure, the algorithm works with the paths database, which contains paths ordered by the TOC and available ad hoc paths. At the end of the process demands on paths are placed into relevant databases.
The algorithm in the TOC's information systems structure and infrastructure manager information systems structure is on the figure 1.

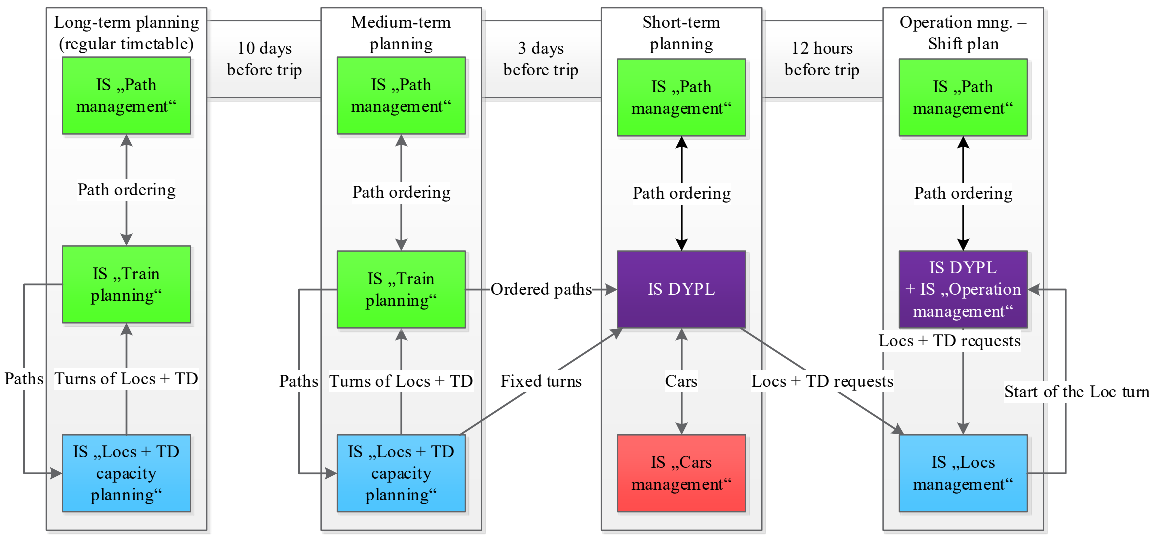

Fig. 1.
Structure of information systems used for train operation planning
Source: authors

The aim of the algorithm is to lay principles for further research on the management optimization of available resources whose are planned in the long term. Those resources have to be listed with the real facts that occur at any time between the entry of the train request into the TOC's planning systems and the output which is a scheduled train in the infrastructure manager's operational control system. For each individual train path, the algorithm will provide basic capability possibilities, then planning of infrastructure capacities and assignment of specific capacities on the railway infrastructure. For example, if there will be a request to secure ad-hoc path from starting point A to a destination B (over a period of more than 1 month), a departure at x and an arrival at x + t, the system will find solution for that situation based on predetermined criteria. The all of new incoming transport requirements will take in account the options that will be defined from the previous planned shipment including in the timetable.
The purpose function *f (x) = min*
Due to the fact, that pattern we are interested in is composed of variable parts, there will be a new pattern, which will work in the same time like a minimization function.

$$C_{c\ opt} = K_1 + K_3 \cdot D + L \cdot Z \cdot K \cdot P_X \cdot S_1 \cdot S_2 + T \cdot L \tag{4}$$

where:
K_1 is a price of proceed and assign of train path and assign of infrastructure capacity;
K_3 is a price related with the day of assignment of train path;
D is a number of path using days;
P_x is product factor (train categories);
Z is a basic price;
K is coefficient reflecting the category of railway line (regional, mainline);
L is a length of train path;
T is a penalty for non-used infrastructure;
S_1 and S_2 are specific factors (weight, ETCS equipped vehicle).

Limitations:
Analyse of requirement on the transport services and available infrastructure capacity. The requirements like system inputs are variable by the character and location of origin. The proposed deal with the three basic types of input requirement (figure 2).

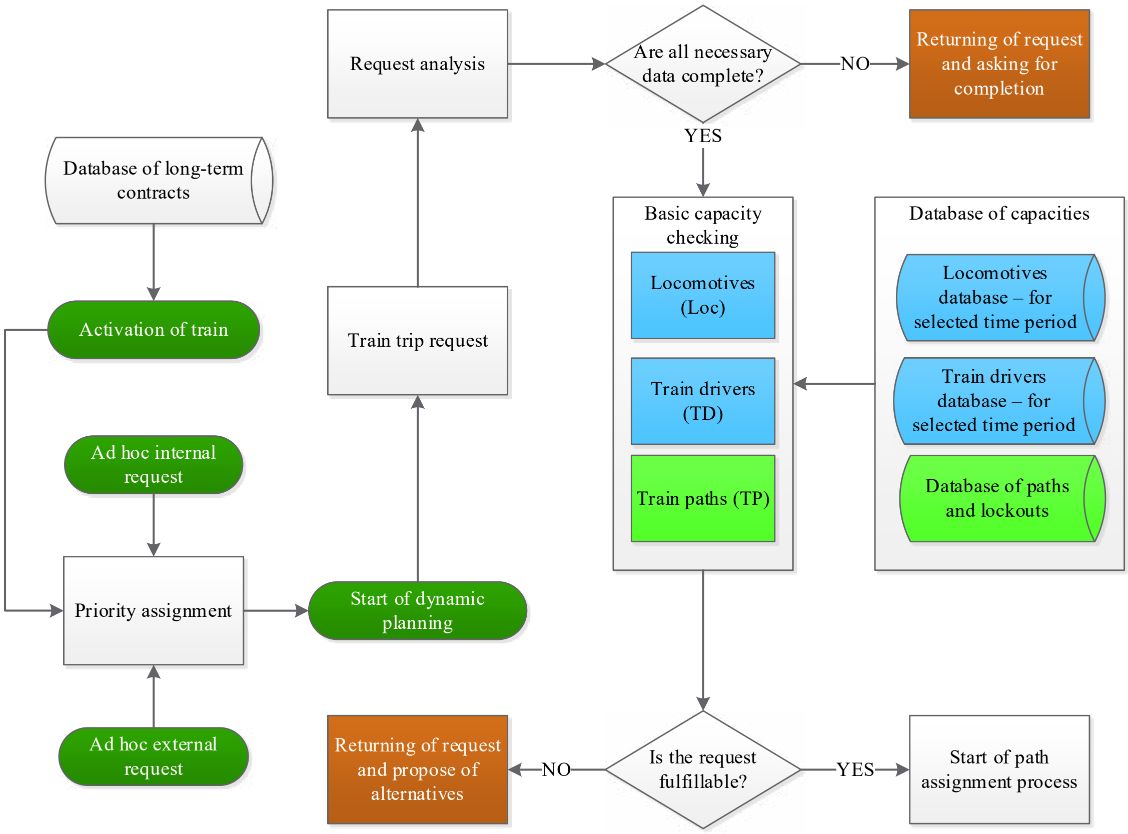

Fig. 2.
Scheme of request analysis and inputs
Source: authors

The first is a requirement that should be the most occurring. That requirement is a train running based on long-term plan (the regular timetable request) with unchanging dispositions and a simple assignment of already scheduled capacities to the given train path. After activation of the long-term requirement (assuming that it is a long-term contract and customer will inform on time, when it will be proceeded), the algorithm is entered in the system. This category also includes regular (daily or almost daily) trains. The creation of train run according to the optimally planned capacities has a direct link to the quantification and assignment of the real costs to a solution for the individual specific business. The assignment of cost will be made on the outputs from the current TOC's operational management information system or another information system.
The second requirement is internal. It could be e.g. the requirement to transport empty wagons to the loading station or the requirement of the TOC's train run for their own use.
The third requirement is a random one-time or random repeated request for transport services (ad-hoc train request).
Individual requests gain assigned priority based on customer information. Priority assignment is not the goal of this paper. On the other hand, it is necessary to present it here, as they will be determined by the customers and by their requirement of transport importance and by train categories.
Between important factors for priority determination belong:

- international train path on the rail freight corridor (RFC);
- another international train path;
- customer requirement on the Just in Time carriage;
- train paths ensure carriage of single load wagons service.

RFC are currently pushing carriers to improve the accuracy of trains running on freight corridors. In specific cases is possible to change the priority of trains. Trains carrying single wagon loads between marshaling yards have to get extra care because the delay of such a train affects to the transport times and the regularity of the operation of next trains.
The first step in the infrastructure capacity solution is paths sorting according to transport type. The instrument load the ordered paths from the relevant database. In the next step, the algorithm tries to find a most appropriate path. The first criterion is using of suitable paths for the definite carriage type. If the carriage consists the single load wagons or groups of wagons for which it is possible to use the route dedicated for the single load wagons services, the path is used. By this process paths that are generally suitable for another type of transport are excluded (figure 3). There remains a review of common freight train paths where a specific product factor is not used.

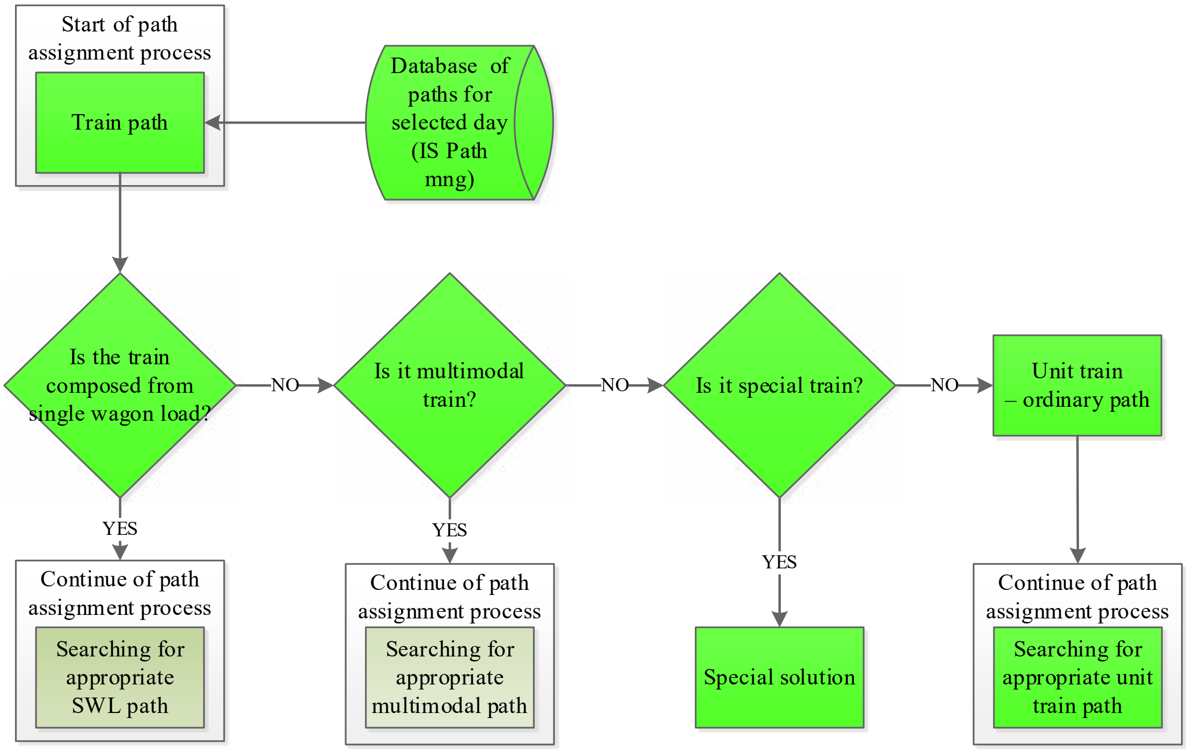

Fig. 3.
Scheme of choosing appropriate assignment process according to products factors
Source: authors

The instrument has been developed mainly as a solution of the process of service provided for unit customer trains without specific features because almost of this type of train are running ad hoc. The freight transport without specific features is a current term of product factor in the price model, which is focused on the trade segment (in this case it means, that it is not passenger transport, single wagon loads or unstandart trains). This case is the most basic one from group of cases with usual unit customer train. The unit customer train is a usual product for propose which is specified in this paper. It checks to see if train path is in the database of ordered paths. If such a path exists, the algorithm assigns that path to a particular train running and after the assignment of the locomotive and the train driver sends a request for activation of the path to the Infrastructure Manager's information system. It is shown in figure 4.
If the algorithm finds the proper path, the algorithm still works. It searching the path with product factor for a usual freight train. The algorithm does not consider the possible combination of the paths and this will be the further scientific activity.
If a suitable train path is found, the path will be assigned and activated as is described in the previous paragraph. If will not be found the proper path with suitable product factor, the algorithm start to find in another product factors (product factors for single load wagon, etc.). If a suitable path is found, a change of parameters (change of the product factor) of the path. This change is realized through the infrastructure manager's information system which ensured in the following process. It includes assigning a route for a given path and then activating the path (figure 4).

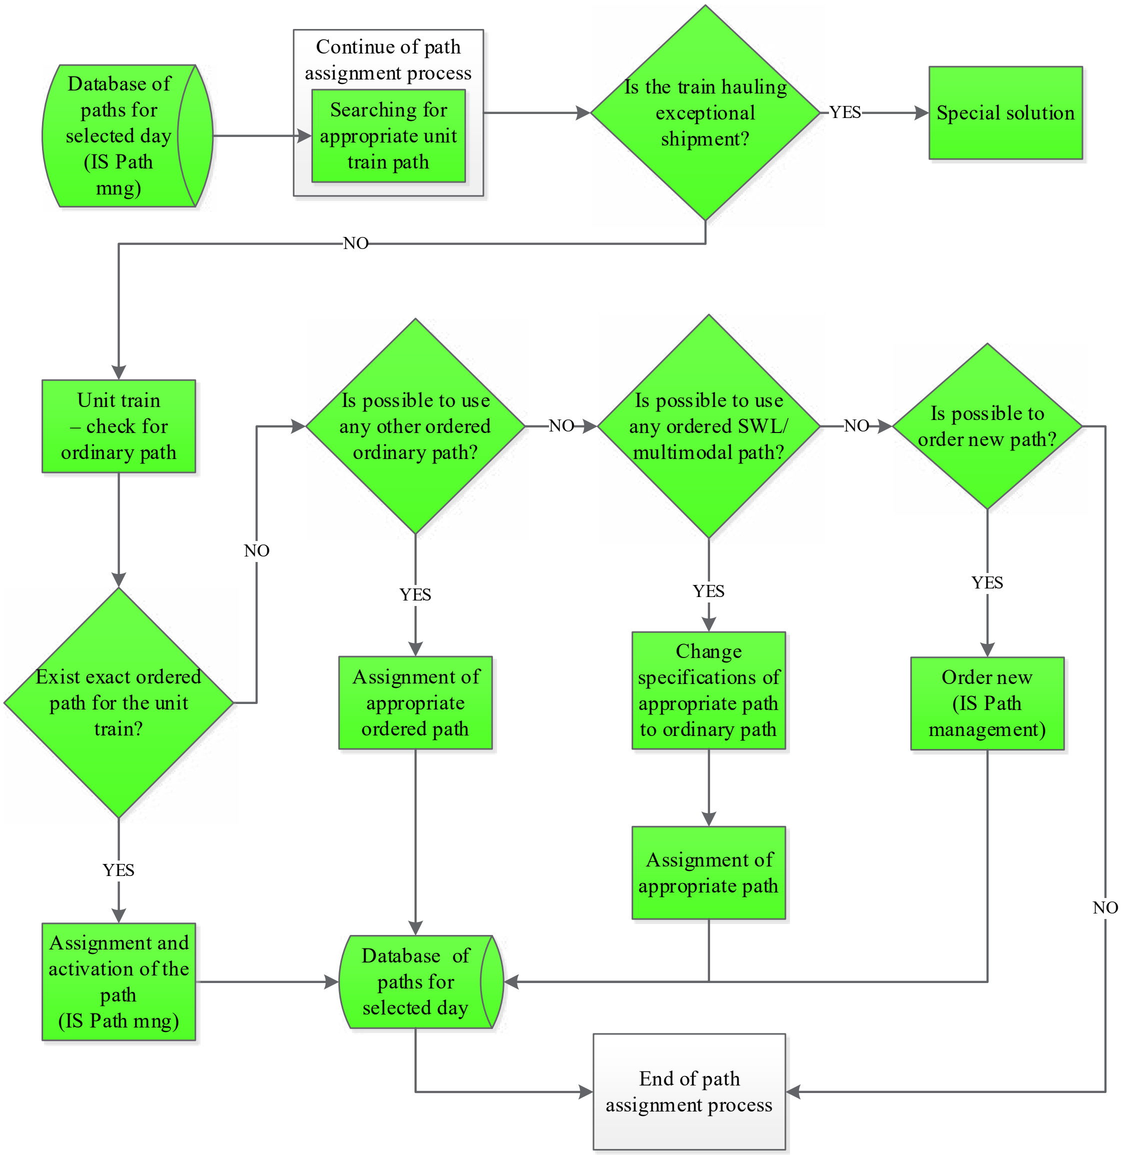

Fig. 4.
Scheme of ensuring train path for ad hoc ordinary unit train
Source: authors

If the path request cannot be accepted, the algorithm uses to the last step, what means sending a request to the Infrastructure Manager's information system to order ad hoc train path. The process of sending a request to ad hoc path is supposed to be used in marginal cases. In the demands for train running, where train path for single loaded wagons is ordered or multimodal train is used the algorithm, too. The specifics of the process are in the different product factor. The process of searching for suitable paths is running similar. In the end of the algorithm the possibility to use specific factors related with ETCS is checked. If the used locomotive is equipped by the ETCS, the specific factor S2 is used (figure 5). If the used locomotive is equipped by the ETCS, the specific factor S2 is used.

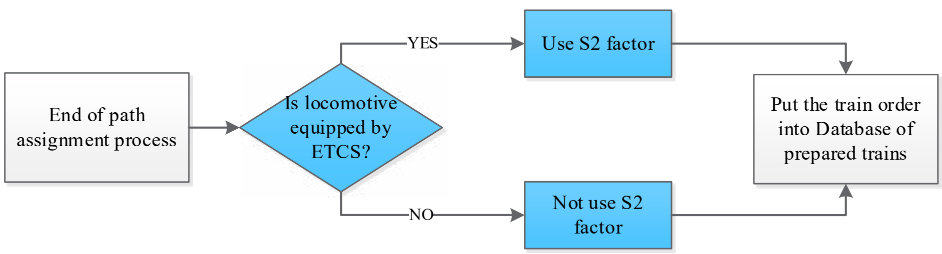

Fig. 5.
Scheme of using ETCS factor
Source: authors

5. Conclusion

The necessity to increase quality, punctuality and efficiency of freight railroad transport on one hand and competitiveness and effort to increase customer service including time flexibility on the other hand put even more pressure on planners and dispatchers. Modern real-time information systems are able to remove routine work in the short-term planning and operational management and simplify the preparation of ad hoc trains running. In this paper is considered the path assignment problem and proposed procedure that allows under real-time information automated assigning of the train paths. The proposed instrument performs dynamic assignment of ad hoc request for train running to appropriate train path through a fast and efficient solution procedure based on the assigning algorithm. The algorithm enables higher utilization of ordered paths. On base of information from customers is possible to reassign the capacities of the sources e. g. locomotives and drives. The capacities that are not at that time assigned are released into the database for other utilization. The procedure has been tested on real-life data from one of the major railroads in Central Europe. Generally, the procedure enables the maximum utilization of train paths and due to that is increasing the efficiency of whole railway system.

ASSESSMENT OF KADENCE ADAPTIVE TRAFFIC CONTROL EFFICIENCY THROUGH HIGH-FIDELITY MICROSIMULATION MODELING

Igor Dakic[1], Aleksandar Stevanovic[2], Nikola Mitrovic[3]
[1] *Institute for Transport Planning and Systems (IVT), ETH Zürich, Switzerland*
[2,3] *Department of Civil, Environmental, and Geomatics Engineering, Florida Atlantic University, USA*

Abstract: Various Adaptive Traffic Control Systems (ATCSs) have been evaluated in past studies. Researchers have usually shown either positive or neutral impacts of these dynamic signal strategies, mostly through the field studies. Due to the high costs for performing the field-based experiments, many field ATCSs evaluations were performed without proper experimental design and thus with compromised scientific rigor. Although simulation models can provide a variety of experimental scenarios, they are frequently questioned for their ability to accurately represent field conditions. This study aims to cover lack of both approaches by introducing a way to develop a high fidelity microsimulation model to investigate effectiveness of Kadence adaptive control in an urban network. In order to provide further evidence that the presented model is an accurate virtual representative of field conditions, an additional validation procedure is conducted through the comparison of modeled and observed durations of average green times. Average green times collected from the field are not based on green times programmed in the field controllers, but based on the actual field green times collected from the controllers' logs. The results show that Kadence ATCS, which was evaluated for the first time in microsimulation, outperformed well-fine-tuned time of the day plans with coordinated-actuated traffic control.

Keywords: Adaptive traffic control systems, Kadence, Microsimulation.

1. Introduction and Background

Different types of ATCSs have been evaluated both in the field and through microscopic simulation, addressing performance of ATCSs and their comparisons to conventional signal control strategies (Mirchandani and Head, 2001; Luyanda et al., 2003; Midenet et al., 2006; Kosmatopoulos et al., 2006; Stevanovic et al., 2009; Stevanovic, 2010; Stevanovic et al., 2016; Dakic and Stevanovic, 2017; Dakic et al., 2018). Microsimulation has reached a level of sophistication that enables more meaningful comparisons, due to its ability to capture real-world conditions in traffic flows and model complex road geometries (Park and Qi, 2005). Tools that provide interfaces between ATCSs and microsimulation emerged in the late 1990s (Nguyen, 1996; Martin and Hansen, 1999). Today, Emulation-In-the-Loop-Simulation (EILS), Hardware-In-the-Loop-Simulation (HILS), and Software-In-the-Loop-Simulation (SILS) are available, which can be used to comprehensively assess performance of ATCSs in a microsimulation environment (Stevanovic et al., 2009; Zlatkovic et al., 2010). Examples of such simulations include SCOOT-VISSIM and SCATS-VISSIM interfaces (Stevanovic et al., 2009). Nevertheless, the amount of related research on the calibration and validation efforts is limited.

Several studies used a genetic algorithm (GA)-based procedure to search for an optimal configuration of microsimulation parameters that would minimize the difference between the simulation results and the field measurements (Park and Qi, 2005; Ma and Abdulhai, 2001). Although both studies showed that the use of a GA can minimize the error between the modelled and observed results, they were constrained to the use of a single Measure of Effectiveness (MOE) for calibrating the model. Consequently, other MOEs might not be well calibrated. A more systematic approach was presented in a study conducted by Toledo et al. (2003), who applied a MITSIMLab tool to an urban-freeway network and used the sensor data to calibrate origin-destination flows and route choice parameters. The validation was based on traffic volumes, travel times and queue lengths.

Park and Schneeberger (2003) introduced a nine-step procedure for calibration and validation, using VISSIM tool to perform simulation experiments. Even though the authors used an extensive set of calibration parameters, the validation results indicated that the simulated distribution of travel times did not follow the travel time distribution observed in the field data. Kim and Rilett (2003) presented a sequential, simplex algorithm-based methodology that was tested on CORSIM and TRANSIMS platforms. The objective was to identify a parameter that would yield the best replication of the observed traffic volumes. Moreover, ten microscopic models of different kinds were tested by analyzing the car-following behavior using the data collected via GPS-equipped cars (Brockfeld and Kuhne, 2004). Model calibration and validation were based on the same data set that contained headway time series.

The study conducted by Hollander and Liu (2008) was intended to guide traffic analysts through the basic requirements for calibrating and validating microsimulation models. They conducted a very comprehensive review of methods and data sets used for calibration and validation purpose. Finally, Stevanovic and Martin (2008) assessed the suitability of evaluating macroscopically optimized signal timings using CORSIM, SIMTRAFFIC and VISSIM microscopic tools. The calibration was based on a vast data sets collected from the field. Findings revealed that when a uniform increase in traffic demand was imposed on each model, a large discrepancy in simulation outputs occurred.

In overall, many previous calibrations were focused on the identification of parameters used to calibrate a model, instead of giving the attention to multiple sources of traffic data used to compare simulation results with the field measurements and further confirm whether a model is calibrated and/or validated. In addition, results of the previous

[2] Corresponding author: aleks.stevanovic@fau.edu

studies did not always provide a strong match of the disaggregated measurements. This study addresses these issues with the two major objectives:

1. Development of a high-fidelity microsimulation model, which represents an accurate proxy of the real-world traffic conditions.
2. Evaluation of Kadence ATCS for a 15-intersection urban network in Miami Dade County, FL. Kadence evaluations in microsimulation have not been previously published in available literature. Therefore, this study represents a unique contribution by comparatively evaluating performances of Kadence and TOD signal timing plans in a weekday PM peak period.

2. Experimental Design

2.1. Study Area

The study network includes a 19-interesection corridor of SR 112/41st Street in Miami Beach, FL, from Alton Road to Collins Avenue in the E-W direction, and from 39th Street to 44th Street in N-S direction (Fig. 1). This corridor was selected for Kadence evaluation due to the congestion level occurring in the weekday PM peak period (4:00 – 6:00 PM). Annual Average Daily Traffic (AADT) varies between 32,000 and 44,000 vehicles per day.
To perform the simulation experiments, we used microsimulation platform VISSIM (PTV AG, 2014) as it is, so far, the only microsimulation model capable of interfacing with Fourth Dimension (Virtual D4) controllers. D4 controller is the only market-available signal controller that is able to replicate operations of the currently field-deployed 2070 traffic controllers and is compatible with Kadence in microsimulation environment. The simulation model is developed for the PM peak period based on the existing geometry, traffic operations, and traffic control.

Fig. 1.
Test-Bed Network: SR 112/41st Street in Miami Beach, FL

To successfully model the field conditions, the data collection process included the following data sets collected under fair weather and pavement conditions: traffic counts, bus schedule and ridership, the travel times, and the signal timings. Given that travel time measurements were collected by the floating car vehicle moving along different paths of the study network, the following routes were identified and observed for the model calibration and validation purposes (Fig. 2b): EB route (from Alton Rd to Pine Tree); WB route (from Pine Tree to Alton Rd); route A (Pine Tree – Indian Creek – Collins Ave – 43rd Street – 44th Street – Indian Creek – Pine Tree); route B (Pine Tree – Indian Creek – 39th Street – 40th Street – Collins Avenue – Indian Creek – Pine Tree); and route C (Pine Tree – Indian Creek – 43rd Street – Collins Avenue – 44th Street – Indian Creek – Pine Tree)

2.2. Model Calibration

The SR 112/41st ST VISSIM model was calibrated according to the driving behavior captured through multiple traffic metrics collected in the field. The calibration process was performed manually by altering the following elements of the simulation model at intersection approaches: desired speed distribution; saturation flow; and diffusion time. Moreover, signalized intersections were defined as nodes in VISSIM. These nodes were further coded to collect turning counts from the simulation. An Excel spreadsheet was designed to use VISSIM outputs and make a comparison to the field traffic counts (Fig. 2a). This spreadsheet was later used for traffic volume balancing, which included adjustments to routing decisions and traffic inputs in order to reflect field-collected volumes. The calibration results are presented in

Fig. 2d and indicate a good match between the observed and modeled TMCs (the coefficient of determination R2 is approximately 0.98).

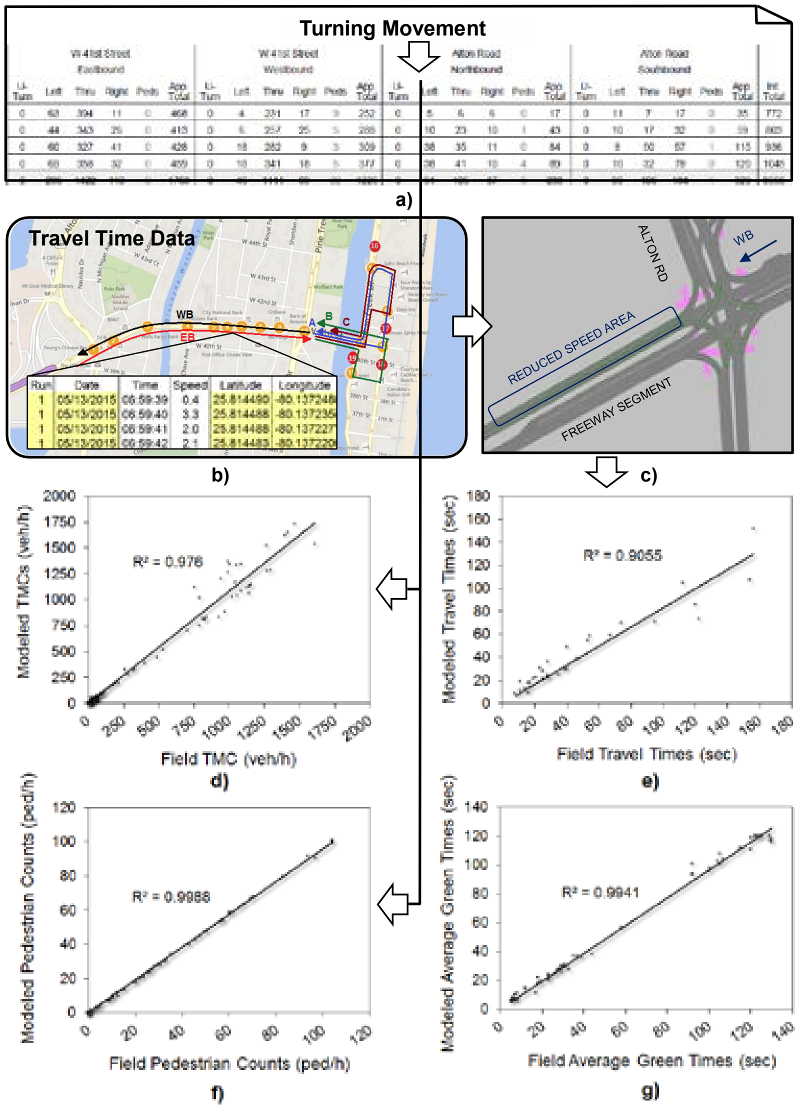

Fig. 2.
Calibration and Validation Results

2.3. Initial Model Validation

The model was validated through a comparison of modeled and field travel times measured along intersection segments. Travel times were collected both by GPS devices (floating car method) and by video recordings of travel runs. The GPS measurements were available in 1-second resolution and contained information regarding the time when the measurement run was performed, the speed of the vehicle, and the latitude and longitude (Fig. 2b). Once again, an Excel spreadsheet was designed to transform latitudinal and longitudinal coordinates and further determine the exact position of the floating car vehicle as it was traveling along the study network for each time stamp. This procedure provided travel times between each pair of signalized intersections. Video recordings were especially instrumental in observing queues and general congestion levels at each intersection; these observations were later used to validate the virtual traffic conditions in the microsimulation model.

One should note that during the initial validation process, even though the model was well calibrated, it was very difficult to obtain a good match with the field travel times in the WB direction (Fig. 2b), as they were underestimated in the simulation. Any effort and change made in the simulation model failed to produce very accurate results. Therefore, it was decided to conduct some additional field observations to identify potential problems. These additional observations revealed that the higher travel times in the WB direction were caused by the existence of downstream queues (spillover from a downstream highway segment), which prevented vehicles to depart from the signal at the Alton Rd intersection. Therefore, reduced speed areas were placed on the downstream segment of SR 112/41st ST in the WB direction to artificially mimic spillover effects from the highway (Fig. 2c). Once this modification was made, a good match between field and simulation travel times was achieved (Fig. 2e). This outcome confirms that the calibration is a very intricate process where multiple factors can impact simulation results. The key factor in this process is spending enough time and effort to observe field conditions and apply proper methods and tricks to realistically replicate those conditions in the simulation model, in spite of all possible constraints.

2.4. Additional Model Validation

In order to further validate the VISSIM model and provide more evidence that it accurately represents field conditions, a comparison was made between: (i) pedestrian counts collected from the field and the ones measured in the simulation model (Fig. 2f); and (ii) the field and simulated duration of average green times (Fig. 2g). Note that the average green times collected from the field are not based on the green times programmed in the field-deployed 2070 traffic controllers, but are computed based on the actual duration of green times collected by the Kimley-Horn Integrated Transportation Systems (KITS) central signal software in Miami's Transportation Management Center database on the days when turning counts and travel-time measurements were collected.
Fig. 3 shows MOE log files that were extracted for that purpose from the field-deployed 2070 controllers. The MOE cycle data was retrieved for the appropriate dates in order to determine the field-averaged green times for all phases/movements at each signalized intersection. The field-averaged green times were further compared with the average green times computed from the simulation using signal log files from Virtual D4 controllers (Fig. 3). These files are given as a VISSIM output at the end of each simulation run, and contain information regarding the distribution of green times for each intersection and phase/movement. The results of the additional validation indicate close match between the field data and VISSIM outputs (with R2 ranging from 0.96 to 0.99). The authors are not aware of any previous studies where such an effort is applied to confirm that signal timings generated in the simulation model match the signal timings from the field. Therefore, these results give an extra weight to the interpretation of the findings achieved from the modeling experiments.

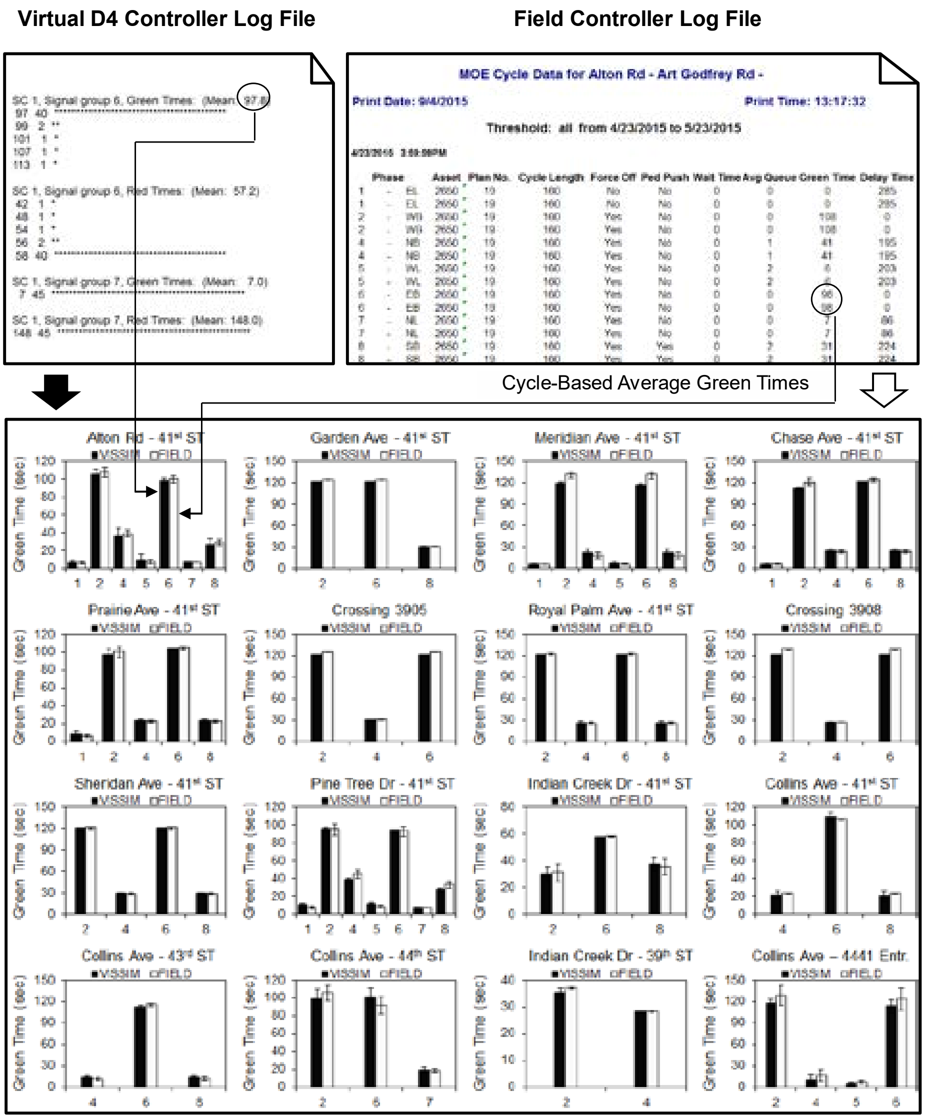

Fig. 3.
Comparison of Modeled and Observed Average Green Times

2.5. Analyzed Signal Control Strategies

The existing TOD signal timings represent actuated-coordinated plans operating with the stop bar detectors placed on the side-street approaches and for the protected/permitted left turn movements. The main-street through phases are coordinated and run under the ‘maximum recall’ function. The cycle length during the weekday PM peak is 160 seconds along the 41st Street, and 140 seconds along the Indian Creek and Collins Avenue. Based on the quality of their performance, it seems that these signal timings were periodically/recently adjusted to accommodate changes in traffic demand.
On the other hand, Kadence is developed by Kimley-Horn and Associates (KHA) and represents an extension from the base ASC Lite algorithms established by the Federal Highway Administration (FHWA). It is integrated as a component of a KHA KITS arterial and freeway management system. The system optimizes signal timing parameters and is comprised of the five principle algorithms for tuning splits, offsets, cycle time, phase sequence, and TOD schedule in real-time. Splits, cycle, and phase sequence adjustments are made based on the data collected from the stop bar detectors, whereas the advanced detectors are used for offsets adjustments and estimation of queue lengths for adaptive operations during oversaturated conditions. Any type of detection (such as inductive loops, radar, video, etc.) is supported.

3. Results and Discussion

The evaluation of the performance of Kadence ATCS related to the existing field traffic operations for the PM peak was performed on different levels: intersection, corridor, network-wide, main-street vs. side-street, and pedestrian levels. To acquire statistical significance of the result, each scenario was modeled multiple times (10 repetitions). The significance level was set at 95%. Each simulation run lasted 2 hours (peak period) and 15 minutes (warm-up time).

3.1. Intersection Level Performance

The most detailed performance measures were assessed on the intersection level (Fig. 4a). First thing to notice is that Kadence outperformed TOD plans in terms of the delay time at the majority of intersections. Due to artificially restricting vehicles from entering the intersection from a westbound residential street by giving priority to the vehicles entering from the left turn lane at the NB approach, we can observe higher delays at Collins Avenue/41st Street in the existing field conditions (TOD). This step was undertaken for model validation purposes, as we determined during the additional field observations that NB left-turn vehicles block the intersection and prevent vehicles from either EB or WB approaches to enter the intersection area, causing higher delay times. This is also an example in which Kadence significantly reduced average vehicle delay. A similar trend was observed when the average number of stops was analyzed at the approach and intersection levels. Once again, Kadence yielded better results than TOD plans at the majority of intersections (Fig. 4b).

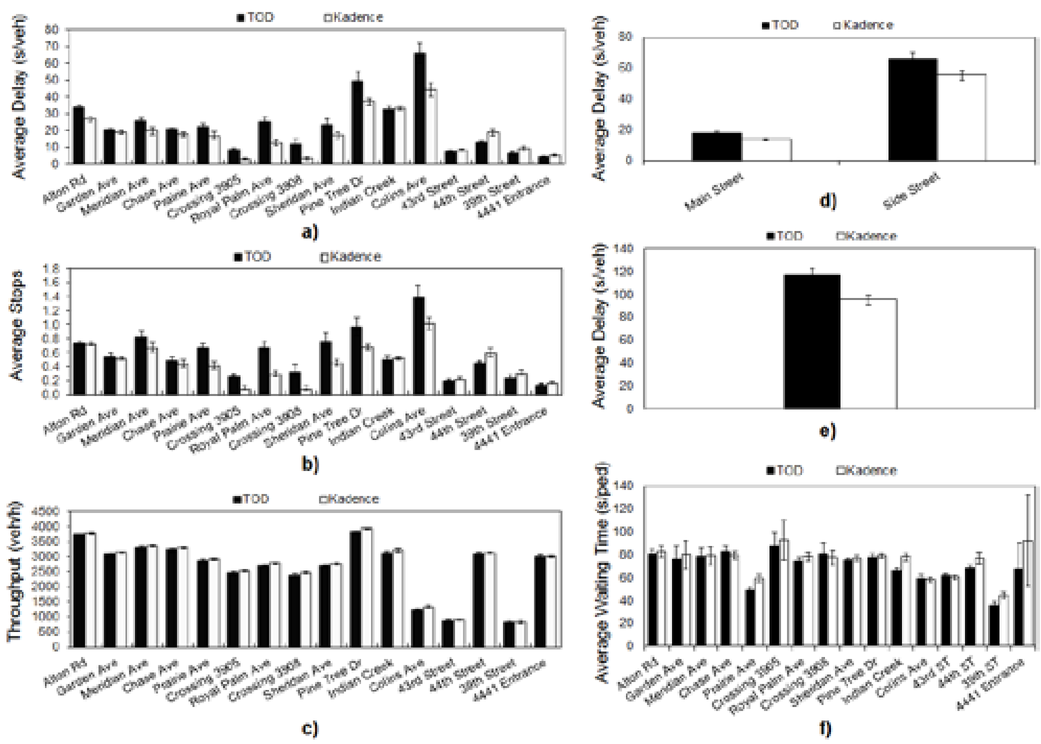

Fig. 4.
Comparison of Measures of Effectiveness on Different Spatial Levels

The analysis of the average throughput (Fig. 4c) shows that the greatest improvements of adaptive control strategy were recorded at the NB approach of Collins Avenue/41st Street intersection, where Kadence increased the average throughput by 7%. These improvements on the approach level are mainly contributed by an increase of 26% in the number of served NB approach vehicles in the left-turn lane, which is one of the most congested segments.

3.2. Corridor Level Performance

The success of signal coordination and traffic progression along the main corridor is best assessed through a corridor travel time analysis (Fig. 5). It can be observed that Kadence reduced travel time on almost every segment in both EB and WB directions along the 41st Street, with improvements ranging between 3% and 56%. The only exceptions are Sheridan Avenue-Pine Tree EB segment and Chase Avenue-Meridian Avenue WB segment, where Kadence increased the travel time by 27% and 2%, respectively (Fig. 5). On the other hand, the benefits of adaptive operations were not acquired on the majority of segments belonging to routes A and C (Fig. 2b). Finally, within route B, one of the most congested segments during the PM peak is a left-turn lane at the NB approach of Collins Ave/41st ST intersection, causing very high travel times in the existing field conditions (Fig. 5). Kadence was able to significantly reduce the average travel time on this segment by 31%. In addition, Kadence also reduced travel time for the following downstream segments: between Collins Avenue and Indian Creek (27%), and between Indian Creek and Pine Tree (49%), further alleviating congestion at Collins Avenue/41st Street intersection.

Travel Time Segment	TOD	Kadence
Alton Rd-Garden	9.2	9.0 [1]
Garden-Meridian	30.6	19.6 [1]
Meridian-Chase	25.4	21.3 [1]

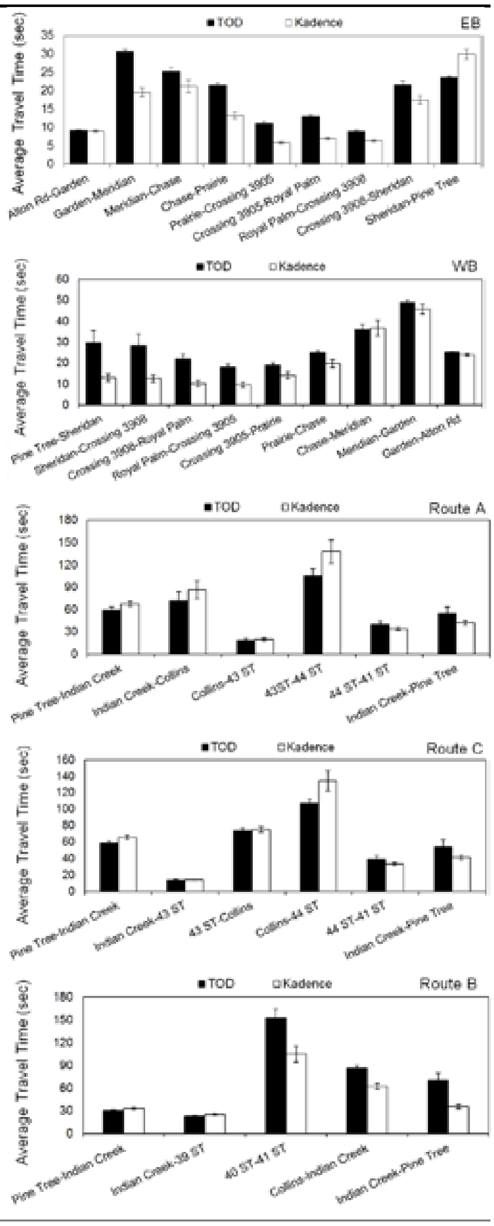
Chase-Meridian	36.1	36.6
Meridian-Garden	48.9	45.7 [1]
Garden-Alton Rd	25.1	23.9 [1]



1 – travel time is statistically significantly different from corresponding TOD travel time

Fig. 5.
Average Corridor Travel Times

3.3. Main-Street Versus Side-Street Performance

Taking into consideration that ATCSs provide a good progression for main-street traffic at the cost of increasing delays for the side-street traffic, we investigated main-street vs. side-street performance based on aggregated approach vehicular delays. The results shown in Fig. 4d imply that Kadence outperformed existing TOD plans in terms of both aggregated main-street and side-street delays during weekday PM peak by 23% and 16%, respectively.

3.4. Network Level Performance

The effects of each analyzed system were also assessed on a network-wide level. The average network delay per vehicle was selected as the most representative network MOE. A comparison of the total network delay time for the PM peak period is given in Fig. 4e. The results show that Kadence yielded a statistically significant reduction of approximately 18% when compared to the existing TOD signal timing plans.

3.5. Pedestrian Level Performance

Prioritizing vehicular traffic at a certain intersection can have certain impacts on the pedestrian delays. Generally, ATCSs are optimal solutions for alleviating congestion problems on corridors that do not have high pedestrian demand. Indeed, analysis of the pedestrian waiting time reveals that Kadence neither degraded the level of service, neither provided benefits for pedestrian movements at the majority of intersections during the PM peak (Fig. 4f).

3.6. Discussion of the Results

In general, the results of the research experiments show moderate, yet significant, contribution of the Kadence ATCS. Although improvements in the individual drivers' travel times are small (e.g. delay reduced for 21 seconds, as shown in Fig. 4e), when such improvements are accumulated over the entire fleet of cars using the analyzed network and over the entire period of consideration (several years), they can bring significant monetary savings. This further justifies deployment of the Kadence ATCS. Even though it is difficult to compare results of these experiments with other similar Kadence deployments (since no previous evaluations in a microsimulation environment have been published), the outcomes of this study are in the same general range of expected ATCS benefits as described in other studies (Stevanovic, 2010). Results from the Kadence evaluation study conducted by Sabra et al. (2013) show that the improvements also belong to approximately the same range of expected benefits.

On the other hand, beside improvements are quite noticeable for vehicular traffic, non-motorized users have not benefited much from the use of implemented adaptive control logic (Fig. 4f). These results are expected, as most of the ATCS's logics are designed to help driving population to better utilize available time allocations at the signalized intersections. At the same time, pedestrians are regularly treated as high-priority users who enjoy such priority almost equally within fixed-time, actuated, or adaptive traffic signal system. Thus, deployment of an ATCS usually cannot bring any new benefits that were not already given to the pedestrians within another form of (more conventional) traffic control.

4. Conclusions

The performance of Kadence ATCS was evaluated through high-fidelity microsimulation modeling. The simulation model was calibrated and validated using extensive data sets collected from the field. Uniqueness of this research is validation of the model through comparison of the average green times from the field and the simulation, showing an excellent match and giving a lot of weight to the model's trustworthiness. Such a well-calibrated model can certainly be trusted to truthfully represent the field conditions. The following generalized conclusions were reached from the study:

- Under the existing conditions in weekday PM peak, Kadence yielded better results than the current TOD signal timing plans by significantly reducing the average network delay per vehicle. In addition, when approach delays were aggregated on the main-street vs. side-street level, Kadence also provided significant improvements for both main and side streets. However, benefits were not examined for the pedestrian waiting times.
- In terms of the travel times, one of the most congested segments within route B, a left-turn lane at the NB approach of Collins Avenue/41st Street intersection, experienced a significant reduction in the travel time under Kadence regime. Moreover, Kadence succeeded to significantly reduce the travel time on the neighboring downstream segments (Collins Avenue-Indian Creek and Indian Creek-Pine Tree), further alleviating congestion at Collins Avenue/41st Street intersection.
- Finally, at the intersection levels, Kadence outperformed the TOD plans at the majority of intersections during the PM peak period.

Future research should address analysis of environmental and surrogate safety measures to potentially examine some other benefits of Kadence ATCS than the ones reported in this study. Also performance of Kadence and TOD signal timing plans should be evaluated in cases of unpredictable traffic fluctuations such as incidents, inclement weather, evacuations scenarios, etc. The use of irregular conditions is critical to evaluate the versatility of and adaptive benefit of Kadence system.

COMPUTER SIMULATION FOR IMPROVING THE TRAFFIC IN AN URBAN INTERSECTION

Cristina Oprea[1], Ştefan Burciu[2], Florin Ruscă[3], Anamaria Ilie[4], Oana Dinu[5], Alina Roman[6]
[1,2,3,4,5,6] *University Politehnica of Bucharest, Transport Faculty, Department Transport, traffic and logistics, Splaiul Independentei, 313, 060042, Bucharest, Romania*

Abstract: Road safety is currently a world-wide problem because both from the studies on the causes of global and national mortality as well as from the statistics from numerous organizations (World Health Organization, Romanian Police, Eurostat, The European Statistics Office), road accidents are one of the main causes of global mortality. Intersections are associated with high rates of collision and injury because they include a large number of pedestrian, cyclist, motorcyclist and vehicle conflict points. Safer intersection design typically focuses on reducing the impact of speed and potential conflicts. The aim of this paper is to identify solutions to improve the traffic and to reduce the number of accidents in an urban intersection. The case study is realized on the intersection resulted from the confluence of Romancierilor Street and Timișoara Boulevard from Bucharest city. The intersection has a very high risk of accidents, being one of the 44 "black spots" identified by the Bucharest Road Police. In the case of uncontrolled intersections (such as this one) the risks for all road users is very high. Some measures for traffic calming should be considered: turning lanes, priority control, vehicle-actuated warning signs, speed reduction etc. Also, some solutions to “control” the intersection should be taken into consideration: - one of the most effective options to reduce death and injury is the provision of well-designed roundabouts that reduce approach speeds and reduce the angle of potential impact; - signalized intersections are designed to separate traffic and potential conflicts through time separation. Using AIMSUN simulation software, the proposed solutions are studied and compared by traffic parameters like speed, queue, number of stops, delay time, saturation index etc. The one having the best values is selected.

Keywords: traffic, intersection, speed, accidents.

1. Introduction

Road safety is currently a world-wide problem because both the studies on the causes of global and national mortality (Spainhour, 2005), (Archer & Vogel, 2000), (Baron, 2015), (Cordonescu, 2014) and the statistics from numerous organizations (World Health Organization, Romanian Police , Eurostat, European Statistics Office) evidence that road accidents are one of the main causes of global mortality.
The European Commission adopted in 2011 the "2050 Transport: Major Challenges and Fundamental Measures" strategy, which sets a common goal of zero-fatalities for the member States in road transport by 2050. Thus, the EU's objective is to halve the number of deaths in trafficking by 2020.
Accidents in road transport, especially those with private cars, are the most numerous and cause the greatest number of victims worldwide (fig. 1).

Fig. 1.
Casualties in road accidents within the EU from 2001
Source: (European Commission, 2017)

Figure 2 shows the number of road accident victims in urban areas in 2014 (persons / milion inhabitants). In developing or transition countries, like Romania, the number of serious traffic accidents has a tendency to increase (Iovu, 2008); 63% of road accidents in Romania were recorded in urban areas, the rate of urban road accidents with casualties being 2.8 times higher than the EU average and 8 times higher than in Sweden.

[1] Corresponding author: cristina_stefanica@yahoo.co.uk

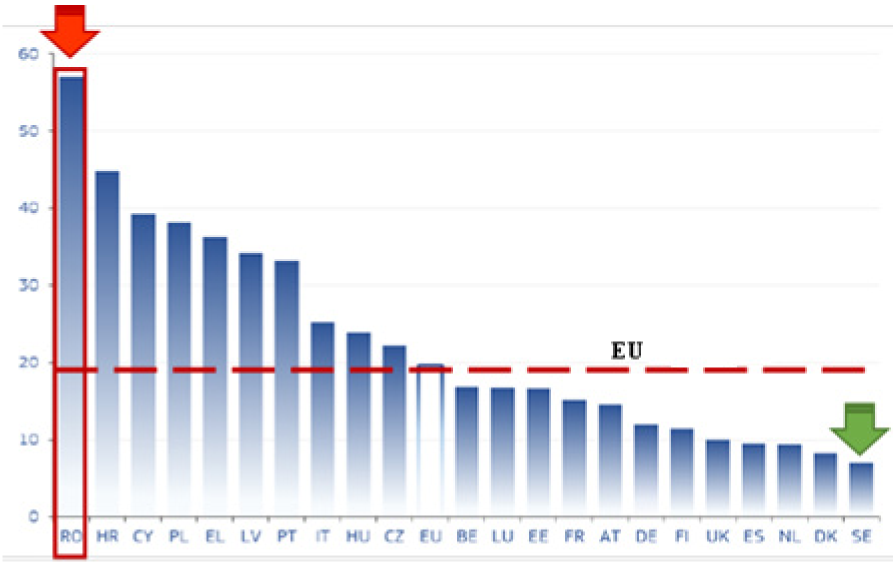

Fig. 2.
Casualties in road accidents within urban areas, 2014 [pers./mil.inh.]
Source: (Iovu, 2008)

At the macroeconomic level, four inter-correlated factors that evidence the risk associated with road traffic are highlighted (Figure 3). Interactions between vehicles, infrastructure and drivers are conditioned by variables characteristic to socio-economic activities. The supply and demand for space mobility, exposure to risk, frequency, location and severity of road accidents bear the impression of the the socio-economic space and, of course, the actions taken to increase road safety.

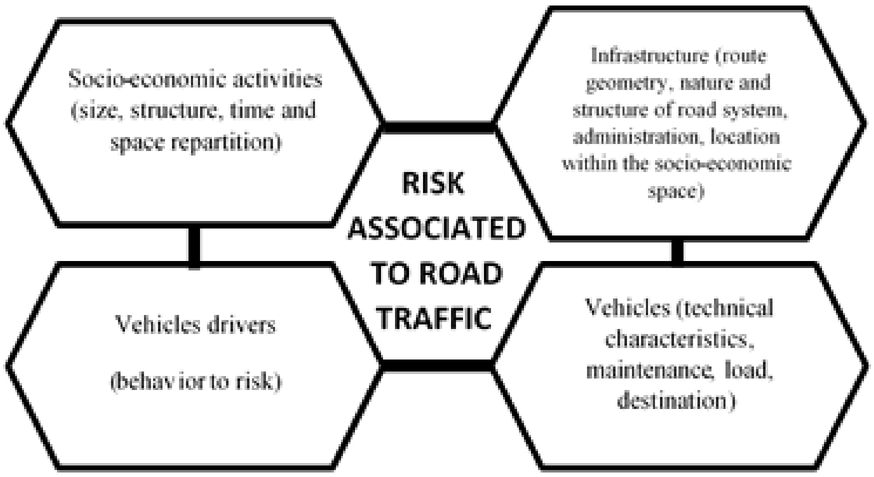

Fig. 3.
Factors affecting the risk associated to road traffic
Source: (EUROSTAT, 2016)

Intersections are associated with high rates of collision and injury because they include a large number of pedestrian, cyclist, motorcyclist and vehicle conflict points. Safer intersection design typically focuses on reducing the impact of speed and potential conflicts. One of the most effective options to reduce death and injury is the provision of well-designed roundabouts that reduce approach speeds and reduce the angle of potential impact to lower-severity side swipes or rear-end crashes.
The provision of overpasses and underpasses (grade-separated interchanges) are cost-effective where large volumes of traffic have to be managed and well-designed merge lanes are provided.
Signalized intersections are designed to separate traffic and potential conflicts through time separation, although they require a level of compliance and road user judgment depending on the detailed design at the location.
In the case of uncontrolled intersections, risks for all road users remain high and the inclusion of lower-cost traffic calming, engineering and technology measures (e.g. raised platform intersections, turning lanes, priority control, vehicle-actuated warning signs, speed reduction) should be considered to reduce risk at such highly dangerous locations on the road network.

The analysis of the intersections is made according to their complexity, taking into account the need to ensure the highest degree of traffic safety that crosses the intersection [3]. The design of intersections must be based on a thorough analysis as they present a high probability of road events happening (accidents). Thus, in order to identify traffic fluidization solutions, an analysis of the existing situation is required.

2. The Study Zone

The analysed intersection is located in Sector 6 of Bucharest and is derived from the crossing of Timisoara Boulevard with the Streets of Romancierilor and Leaota. The intersection has a very high risk of accidents, being one of the 44 "black spots" identified by Bucharest Road Police (fig. 4).
According to the legislation in force, the traffic arteries forming the analysed intersection are classified as follows:

- Timişoara Boulevard falls into category III (collector street) - takes traffic flows from the adjacent streets with 2 and 3 lanes per way, respectively;
- Streets Romanciers and Leaota fall into category IV (street of local use), providing access to current housing and services being provided with one lane per way.

From the point of view of the number of intersecting paths, the intersection is simple, with only two intersecting paths being involved (Timişoara Boulevard with the Romancierilor and Leaota streets).

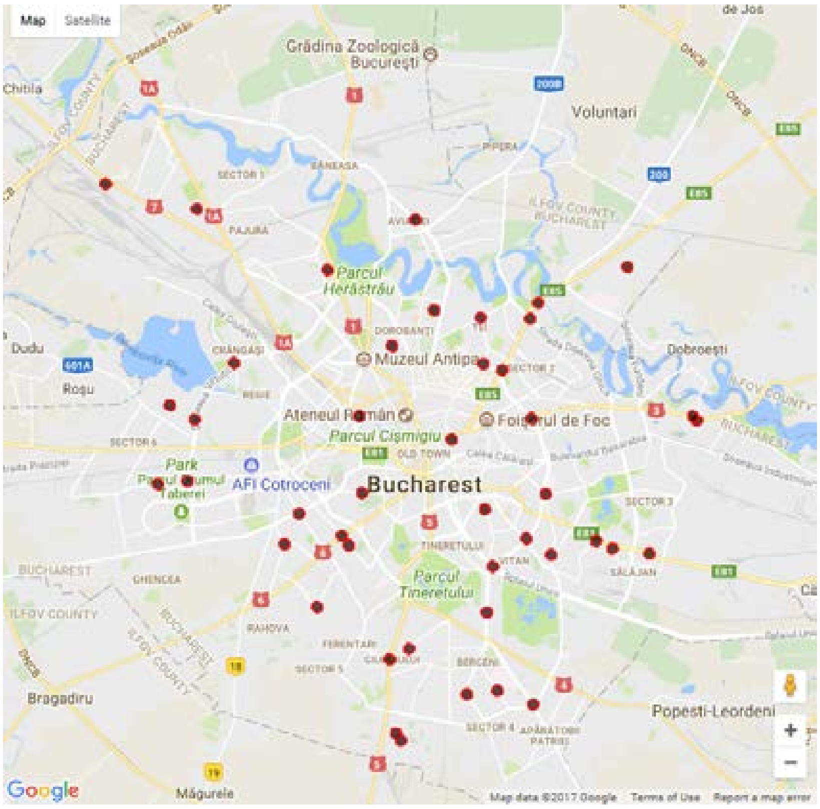

Fig. 4.
"Black spots" in Bucharest
Source: Mediafax

The traffic measurements were realized during the morning and the evening peak hours (7.00 – 9.00 and 17.00 – 19.00) and duaring the off peak hours (11.00-13.00). Traffic flow values obtained from the measurements are presented in figure 5 and centralised in Table 1.

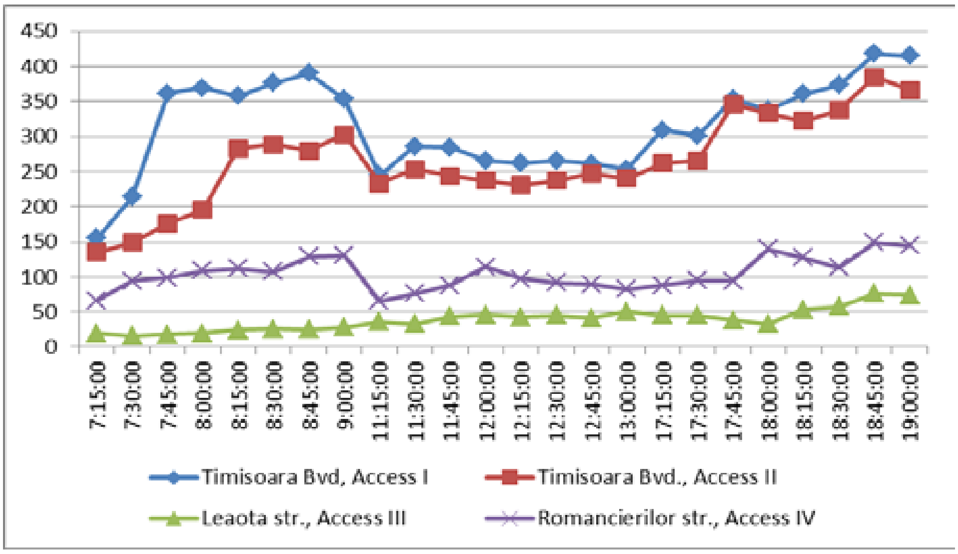

Fig. 5.
Traffic flows [equiv.veh./h]

Traffic flows [equiv.veh./h]

ACCESS	**Limit traffic values [equiv.veh./h] [ped/h]**		
	Morning peak	**Off peak hours**	**Evening peak**
Timisoara Boulevard, Access I	1477	1081	1567
Timisoara Boulevard, Access II	1155	955	1411
Leaota Street, Access III	103	180	262
Romancierilor Street, Access IV	478	360	533
Pedestrians	798	432	990

3. Solutions to Improve Traffic

Some solutions to "control" the intersection might be:
- one of the most effective options to reduce death and injury is the provision of well-designed roundabouts that reduce approach speeds and reduce the angle of potential impact;
- signalized intersections are designed to separate traffic and potential conflicts through time separation.

Given the structure of the intersection and taking into consideration that it includes a tram line, a roundabout is not suitable. Further on, we are going to study the case of introducing traffic lights in order to separate traffic and potential conflicts through time separation.
In order to build the model in AIMSUN, the following data was required (TSS, 2018), (Roşca & all, 2013):
- Intersection layout – the map of the area, the number of lanes for every section, possible turning movements, speed limits for every section.
- Traffic Demand Data - vehicle types and their attributes, flows at the input sections (entrances), turning proportions at all sections;
- Traffic Control - location of signals, the signal groups, the cycle duration and the duration of each phase.

The simulation was done under the following assumptions:
- The simulation warm-up is half an hour, long enough to reach the considered regime
- The simulation time is one hour - in the evening peak hours where we reached the maximum traffic flows (table 1);
- Different structures for traffic light cycle TC =90s, 120s, 140s.

Currently, the intersection is not signalised (fig. 6). Using AIMSUN simulation software we simulated the present situation characterised by the measured traffic flows and pedestrians flows (fig. 7).

Total	532	458	990

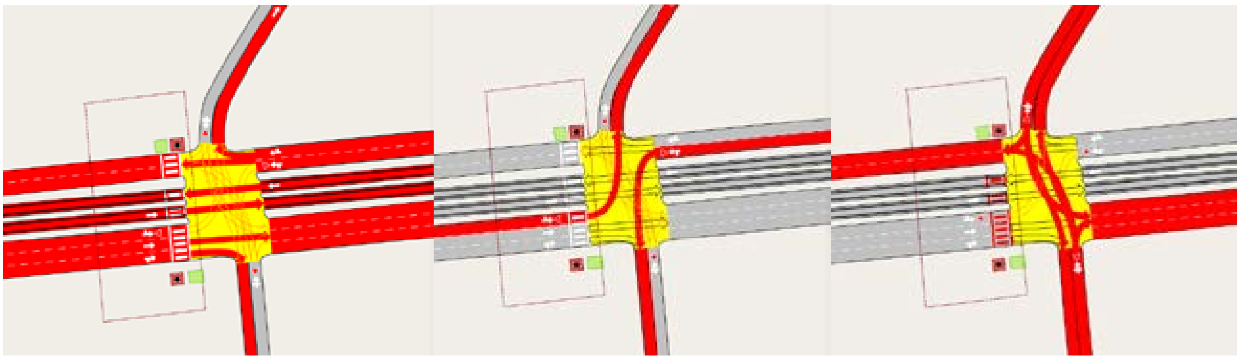
c)

Fig. 7.
OD matrices – a) cars; b) trams; c) pedestrians

By simulating the current situation of the intersection, the performance indicators values are:

- Delay time: 271 s/km
- Mean queue 65 veh.
- Number of stops: 0.59 stops/veh./km
- Speed: 33.88 km/h

Further on we consider the traffic light cycle of 90s, 120s and 140s, each cycle being characterised by three phases (fig. 8; fig. 9).



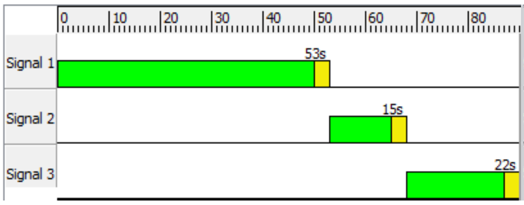
a) b) c)

Fig. 8.
The three phases from a traffic light cycle: a) phase 1; b) phase 2; c) phase 3

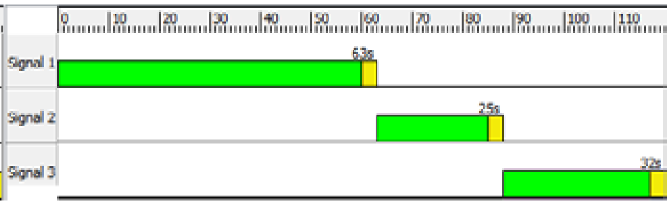
The access into the intersection is saturated when incoming vehicles wait more than one stopping cycle to enter the intersection (STAS 10144/6, 1991). The saturation degree of an access, G_{st}, is:

$$G_{st} = \frac{F_s}{F} \qquad (1)$$

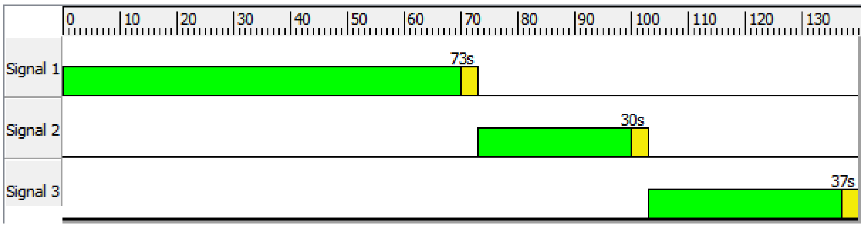
where:
F_s represents the number of saturated green phases in peak hours
F – total number of green phases at peak hours.
For $G_{st} > 0.3$ the intersection redevelopment is necessary - the introduction of a new equipment for routing or a new organization.
For T_C = 120s all the vehicles pass the intersection on the green light in peak hours. The saturation degree is Gst=0.



T_C=90s



T_C=120s



T_C=140s

Fig. 9.
Traffic light charts

In table two a comparison between the measure of performance is realised.

Table 2
Comparison of the measures of performance

Traffic parameters	No traffic lights	Traffic lights					
		TC = 90s	Variation [%]	TC = 120s	Variation [%]	TC = 140s	Variation [%]
Delay time [s/km]	271	173	-36,16%	139	-48,71%	140	-48,34%
Mean queue [veh]	65	45	-30,77%	40	-38,46%	42	-35,38%
Number of stops [#/veh/km]	0.59	0.68	15,25%	0.57	-3,39%	0.57	-3,39%
Speed [km/h]	33.88	31.43	-7,23%	28.42	-16,12%	28.31	-16,44%

As it can be seen from table 2 the best structure of the traffic light cycle is TC = 120s; almost all traffic parameters are improved. The variation of the considered measures of performance is set by a 48.71% decrease of the delay time, a 38.46% decrease of the mean queue, a 3.39% decrease of the number of stops and a 16.12% decrease of the speed. The decrease of the speed is of only 5 km/h; considering the improvement of the other performance indicators, this decrease is insignificant. The queue dissipation is much facile for the proposed traffic lights cycle.

4. Conclusion

Traffic simulation models have proven to be helpful in analysing complex traffic situations that exist beyond the scope of the traditional analytical methods.

Using the AIMSUN simulation software there were analysed some solutions to "control" the intersection, the chosen one being to introduce traffic lights in order to separate traffic and potential conflicts. The performance indicators (average delay, average number of stops, mean queue and average speed) showed that the indicated solution is the one with the traffic light cycle TC =120s.

The saturation degree for the chosen solution is zero meaning that all the vehicles stopped at red light will pass on the green light that follows.

REMODELING APPROACH TO ESTIMATE STOCHASTIC FREEWAY CAPACITY

Anton Sysoev[1], Semen Blyumin[2], Alexander Galkin[3]
[1,2,3] Lipetsk State Technical University, Lipetsk, Russia

Abstract: To study the freeway section capacity and to manage it further, it is necessary firstly to construct a model allowing estimating the dynamics of capacity variation changes. here are certain approaches giving a way to determine freeway section capacity. The main concept still follows the idea that "capacity is the maximum number of vehicles, which could be managed by a particular freeway section under certain conditions". It is worth noting, that capacity does not depend on the traffic flow, however, it depends on the other parameters of the traffic flow. According to American Highway Capacity Manual, German Capacity Manual and Russian Capacity Guidelines, these parameters are geometric characteristics of the road, traffic flow characteristics, traffic light control parameters (cycle time, its distribution through phases, etc.). Naturally, it is a fact that when analyzing the bandwidth, it is advisable to include the values of the selected parameters not only of the current time interval, but also of the interval preceding the current one. This gives the process under consideration natural dynamics. It was found out, that the freeway section capacity varies over time and can be described by a random variable with some statistical distribution. Studies presented this fact, in most cases give the Weibull distribution to describe capacity the best. Based on the thing, that capacity cannot be measured directly, but only at the moment of traffic congestion, a good solution is to use the concept of "black box" to solve the problem to simulate the process. In this case, we operate with the remodeling strategy, when the process described by the model, could be remodeled by the other structure. The paper present the neural network approach to remodel freeway section capacity.

Keywords: stochastic freeway capacity, mathematical remodeling, neural networks.

1. Introduction

Taking into account fast-growing number of vehicles in European and world transportation networks, a special attention should be given to the improvement of existing schemes to model these systems with the goal to their further optimization. Increasing transportation mobility of the population and increasing number of cargo transportations cause supplementary delays in key points of transportation networks. During detailed investigation of such areas, it is necessary to concentrate on freeways as main components of the network, which provide connection between large important transport nodes (for example, big cities and cargo warehouses) of the network. Main characteristic of the freeway, which provides a high quality level of its functioning, is the capacity defined by a number of regulation documents as "the maximum number of vehicles, which could be managed by a particular freeway section under certain conditions".

This definition is very abstract and raises a number of questions. For example, how depends a freeway capacity on a number of external factors? Answers to such questions can be obtained, for example, from Russian Guidelines to estimate road capacity, containing a set of 16 adjustment coefficients, which take into account geometric landscape features, weather conditions, the presence of buildings near the road, etc. However, this approach does include the random factors, generated by combinations of the features mentioned above and supported by instant psychological indicators of vehicle drivers.

It was found, that the freeway capacity is a stochastic value and could be described by some statistical distribution function. Thus, at each specific considered time moment, the capacity has a new random value, and it is only possible to say which distribution fits this value the best. Further this approach will be detailed described. But it seems not precisely right, because it is obvious, that the value of the capacity in every moment depends on the parameters of the traffic flow not only in this moment, but also on moments prior to the analyzed. The paper proposes to build a procedure that would add the dynamics of the stochastic value of the freeway capacity.

2. Study

2.1. Stochastic Approach to Estimate Freeway Capacity

As it was mentioned above, there are two groups of approaches to estimate freeway capacity. The first deterministic group considers that capacity is a constant value. This line is presented in HCM (*Highway Capacity Manual 2010*), HBS (*German Highway Capacity Manual 2015*), Russian Guidelines to Estimate Road Capacity (*ODM 2012, Rosavtodor*) and others (*Sysoev, 2016*). The second stochastic group, unlike approaches from the first group, assumes, that capacity has a random nature and is a stochastic phenomenon. Following this idea freeway capacity could be estimated as a breakdown, which occurs in a flow in a moment when flow equals capacity. It means that one can estimate this value using a mathematical model of statistical distribution function.

The idea to understand freeway capacity as a stochastic number was firstly formulated in *1986 by Van Toorberg*. Further many researchers followed this idea.

[1] Corresponding author: anton_syssoyev@mail.ru

In the year *2000 Lorenz and Elefteriadou* also assumed that the freeway section capacity value could vary depending upon tolerable risk level of agencies. *Brilon and Geistefeldt in 2009* investigated the reliability and efficiency of German freeways to introduce capacity design value. They determined the traffic efficiency of freeway sections and found that the maximum degree of freeway saturation occurs at a flow rate, which is 90% of conventional capacity.
Ozbay and Ozguven in 2007 estimated distribution curve to interpret capacity value. The results of their study demonstrated that a steep 20 curve represents a minimal change in breakdown probability for a specific breakdown value interval. *Geistefelt in 2008* compared the deterministic and stochastic capacity of a freeway in Germany. He proposed to compare the capacity distribution function with the flow-speed diagram. He also introduced a linear relation between the median value of the capacity distribution function and the conventional value of capacity for a number of German freeway sections. *Modi et al. in 2014* compared two capacity estimation methods: Van Aerde flow-speed diagram and the Product Limit to propose the best capacity estimation method. Authors believed the stochastic approach is not suitable because it is complicated in practice for a detailed operational analysis such as ramp metering.
In *1986 Van Toorberg* proposed to use an analogy of lifetime analysis to describe stochastic nature of the freeway capacity. This procedure is called Product Limit method and its function indicates the probability of exceeding the capacity of a section. Constructing the capacity distribution function based on the Product Limit method, we have

$$F(q) = P(q_c \le q)$$

or

$$F(q) = \frac{N_c}{N} ,$$

where $F(q)$ is the distribution function of the capacity, q_c is a capacity value, q is observed flow in the time interval *i*, N_c is the number of observations of $\{C\}$ with $q \ge q_i$, N is the total number of observations of $\{C\}$ and $\{C\}$ itself is a set of congested flow observations setting.
The probability that the capacity is greater than traffic flow is defined by $G(q)$ as

$$G(q) = P(q_c > q) .$$

This function could be estimated by $1 - F(q) = 1 - P(q_c \le q)$ and using Product Limit method

$$G(q) = \prod_{qi} \frac{K_{qi} - d_i}{K_{qi}} ,$$

where K_{qi} is the number of observations in $\{S\}$ with $q \ge q_i$, d_i is the number of failures, $\{C\}$ is a set of congested flow observations setting, $\{Q\}$ is a set of free flow observations setting and $\{S\}$ is the setting of the total observations.
It should be noted, that the Product Limit method is dependent on traffic flow state. To use this methodic it is necessary to choose the criteria indicating moments of switching flow conditions from free to congested. Common criteria used in many papers is traffic flow speed. Speed value indicating this switch could be estimated using speed-flow diagrams. And for example, such speed threshold is 70 km / h for German 2-lane freeways and 60 km / h for German 3-lane freeways.

2.3. Remodeling Concept

The natural fact, that when analyzing the capacity in the current time interval, it is reasonable to include values of the selected parameters from the previous interval, to add the process dynamics. Regardless of which model is used, to estimate the freeway section capacity, this problem has to be fixed. The approach which could provide the new model to describe the capacity based on existing models is Mathematical Remodeling (*Sysoev, 2018* and *Galkin, 2017*).
This is an approach to describe complex and / or composite systems based on the transition from mathematical or simulation models of one type to models of the other unified class. Depending on purposes and specific applied tasks, various interpretations of remodeling are possible. A theoretical model of some dependency built on the basis of its physical background, can have a structure which is quite complex and not appropriate for further analysis. In this case an array of dependency "input-output" data can be generated (which can be inaccessible under real conditions) and a simpler model of some unified structure with the required accuracy could be proposed. This is an approximation remodeling. To construct a new model a neural network and neuron-fuzzy models could be applied. In this case a remodeling has a neurostructural nature (*Saraev, 2018*).

2.4. Neurostructural Approach to Remodel Freeway Section Capacity

The paper presents the algorithm used neurostructural approach to remodel freeway section capacity. It could be formulated in the following way.
Step 1. To divide the whole observed data into two subsets: (a) "congested" intervals, where the capacity rate could be estimated directly and (b) "fluid" (censored) intervals, where the capacity are obtained as Weibull-distributed random value. The criteria to separate intervals must be predefined at this step.

Step 2. Using the data sample obtained on Step 1, to train the neural network model with the predefined structure. On this step the analysis of the model accuracy must be done and corrections (in case of unsatisfied results) should be applied.
Step 3. Using the model obtained on Step 2, to estimate capacity rate within the new data set.
The proposed scheme is concerned to be a remodeling approach because it combines different ways to estimate capacity and presents a unified model to simulate this parameter.
Further are given numerical experiments to prove the sustainability of the proposed scheme.

2.5. Numerical Experiments

2.5.1. Scope of Experiment

The initial for the modeling data obtained by the loop-detector system from German Autobahn A57. They are 1-minute intervals array. Since only one segment of the freeway was involved in the study, some constant parameters (such as number of lanes, geometric characteristics, etc.) were neglected. The average speed in the current and previous time intervals, the percentage of trucks were considered as factors. Since the loop-detector system provides separate information on average speeds of personal vehicles and trucks, the average weighted speed indicator was used. Data were aggregated in 3, 5 and 10 min intervals and their different combinations to train and test neural network were applied.
To remodel the freeway capacity, various different structures of neural network were investigated and it was determined, that the best result demonstrated the network with one input layer, one hidden layer consisting of 13 neurons and the output layer. In its analytic form the model can be written as

$$q_c = \sigma\left(w_{output,0} + \sum_{i=1}^{13} w_{output,i} \cdot \sigma\left(w_{hidden,i} + \sum_{j=1}^{3} w_{ij} x_j \right)\right),$$

where q_c is a freeway section capacity (veh / h), $x_j = \{v_{cars}(t), v_{cars}(t-1), trucks(t)\}$ are factors (average vehicles speed (km / h) in the current and previous time intervals and the percentage of trucks in the current interval); $w_{output,i}$ and w_{ij} are identified weights on output and hidden layers respectively; $w_{output,0}$ and $w_{hidden,i}$ are biases on output and hidden layers respectively, $\sigma(\cdot)$ is an activation function.
Numerical experiments shown, that the best results give the logistic function on a hidden layer

$$\sigma(net) = \frac{1}{1+\exp(-net)}$$

and the linear function on an output layer

$$\sigma(net) = net.$$

To train the defined neural network model, it was prepared a data sample including input parameters mentioned above and output capacity values obtained by the presented algorithm. The criteria to specify the time interval as congested was the average speed below 70 km / h (then the current flow rate was used as the actual capacity value). Fig. 1 presents the speed-flow diagram for the section gathered data from which were used to train the neural network model.

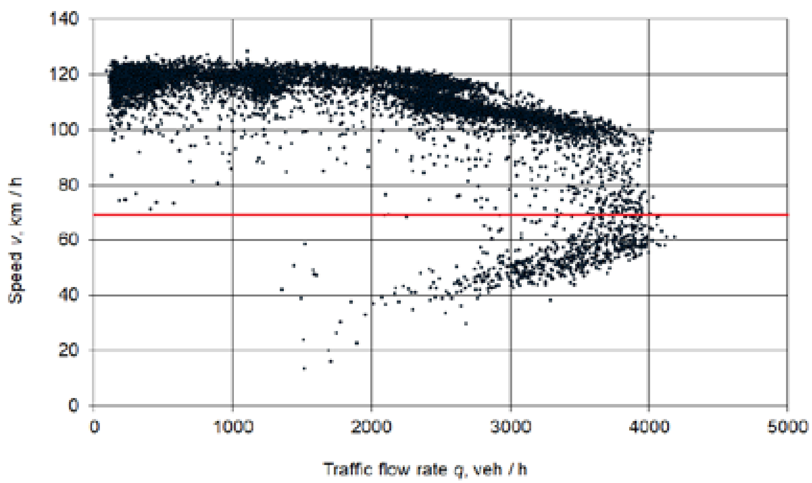

Fig. 1.
Speed-flow diagram for the section applied to the network training
Source: Ruhr-University Bochum research

In cases when the capacity rate value was not measured directly, output values were simulated as a random Weibull-distributed value with defined parameters typical for this freeway section. Different variants of neural network training and testing based on the duration of time intervals were studied. Presented numerical results demonstrate the duration of training intervals of 1 min and the duration of test intervals of 5 min, when the size of training sample was 393 120 intervals, the size of testing set was 26 496 intervals.
To estimate the correctness on the results it was calculated number of cases when the network gave output capacity values smaller than traffic flow rates from the one side and compared with time intervals with average speed below 70 km / h. The accuracy of the network with this approach is about 79%. Fig. 2 shows the comparison of the results obtained by the proposed approach and measured average speed and traffic flow rate. Red boxes showed congested intervals according to speed threshold (smaller than 70 km / h) and according to the traffic flow rate bigger than found capacity.

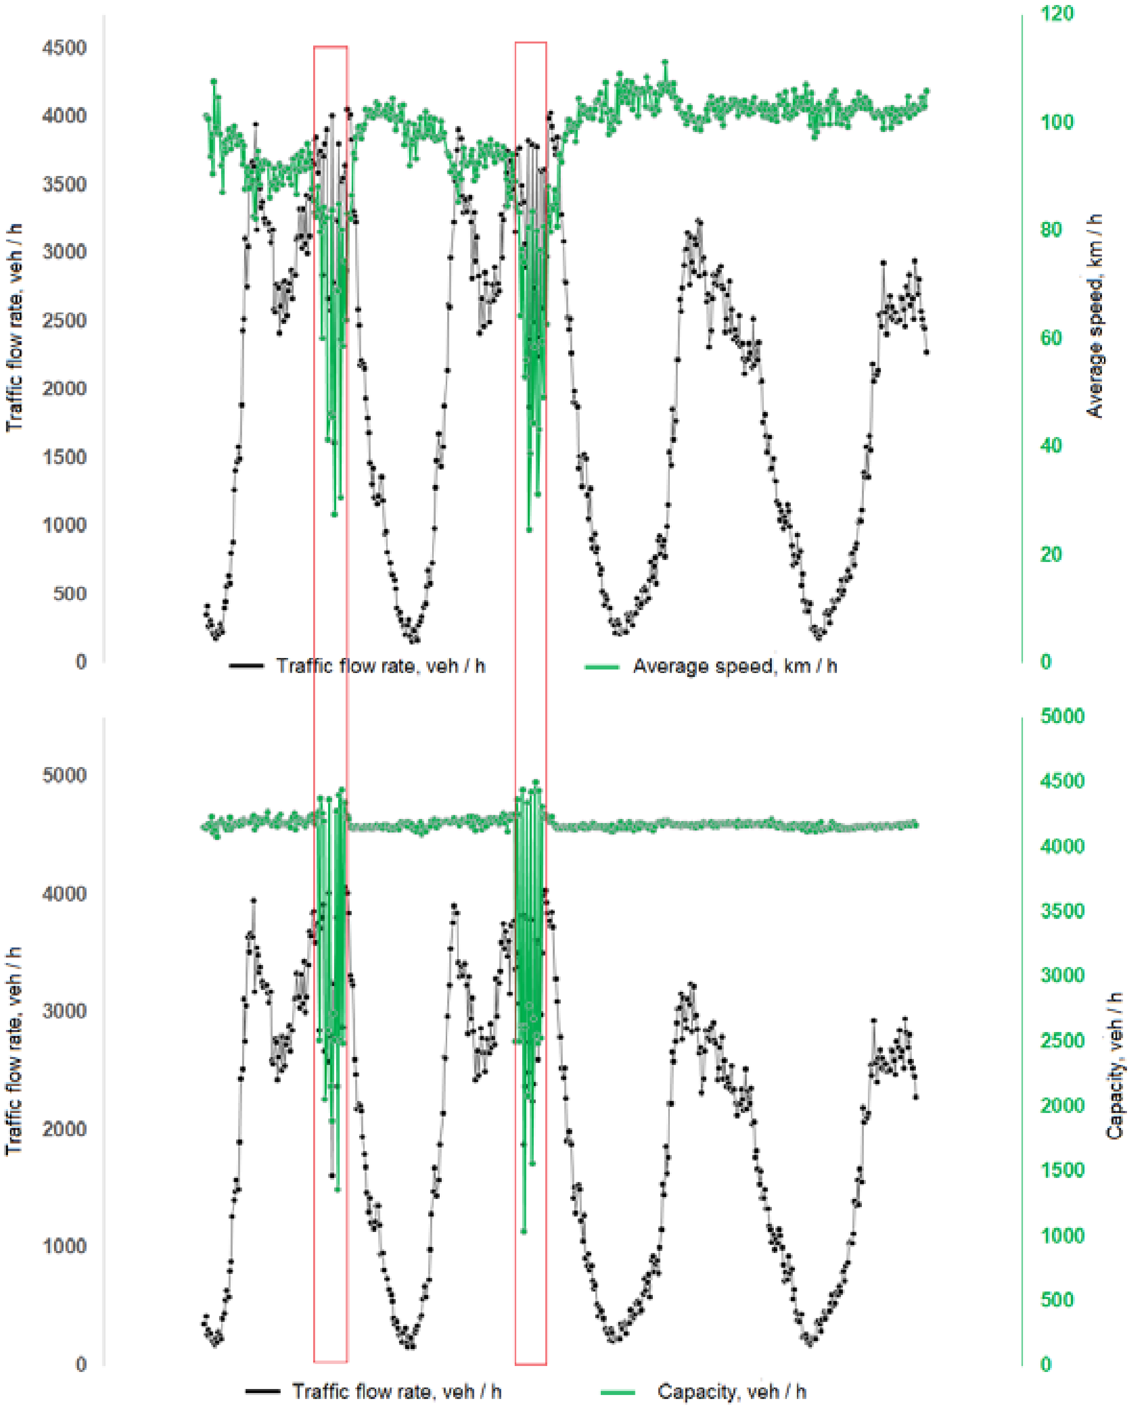

Fig. 2.
Comparing measured parameters of traffic flow within estimated section and found based on the proposed approach capacity

3. Conclusion

There are two groups of approaches allow to estimate the value of freeway section capacity. Natural (and confirmed empirically) way to treat this important parameter as a random value with a certain statistical distribution. Regardless of which approach to estimate capacity is used, there are time intervals where this parameter could be measured directly. It occurs when the traffic flow has a congested regime. In the other time intervals capacity rate could be only estimated. The proposed approach allows to remodel the estimation of freeway section capacity, i.e. to build an analytical model representing the estimated parameter, based on data obtained by direct measurements in some cases and probabilistic estimates in others. The presented neural network model allows adding the dynamics to stochastic capacity in the current time interval by including flow parameters from the previous time intervals. It should also be mentioned, that the traffic flow parameters (primarily section capacity) could be estimated at fixed in the meaning of time duration interval. The perspective problem is to find such a duration of time interval, using of which will give more adequate (in some sense) results.

MODELLING AND CALIBRATION OF MICROSCOPIC SIMULATION MODEL CORSIM

Yusuf Kağan Demir[1], Hatice G. Demir[2]
[1,2] Faculty of Engineering, University of OHÜ, Niğde, Turkey

Abstract: A simulation method is an effective tool in analyzing the various dynamic problems in recent years. Today, many studies related to Traffic Engineering and Transportation benefit from a simulation method. A simulation model reflects the real system through the instrument of mathematical models of operation relations in the system over determined time. Models are developed in order to evaluate the different design and control scenarios. Traffic flow simulation models are divided into three classes according to the detail level of simulation. These are microscopic, mesoscopic and macroscopic. CORSIM (CORridor SIMulation) has been developed by FHWA (U.S. Federal Road Administration), is one of the tops most used simulation software for transport professionals. The performance of the software has been tested and is used continuously by FHWA in many studies. CORSIM can integrate urban road and highway networks to each other, thus it is possible to test the interaction of the two types of network. CORSIM also offers to intervene to networks thanks to built-in control devices. As an example, Istanbul European side of the Bosporus Bridge near Freeway O1, 2.5 km part, was modeled and calibrated with CORSIM. Traffic Software Integrated System 6.1 software package was used. As a result of the calibration, the selected traffic behavior can be successfully represented by CORSIM according to the test criteria. The Erlang distribution seems to be particularly successful in modeling speed. For this reason, the Erlang distribution will be used in subsequent CORSIM simulations. With the help of calibrated CORSIM, the traffic control methods to be applied to the working segment and the reaction that the traffic will give can be predicted. Thus, it is possible to test the validity of the work in the laboratory environment before applying it.

Keywords: CORSIM, Modelling, Calibration.

Introduction

In general, simulation is defined as a dynamic representation of some part of the real world achieved by building a computer model and moving it through time (Drew, 1968). Simulation is a mathematical and logical representation of real-world system and simulation models aimed to develop to evaluate different control and design scenarios.
Simulation models are designed to emulate the behavior of traffic in a transportation system over time and space to predict system performance (Drew, 1968). Traffic simulation models can be classified based on different criteria's. The most common classification is according to type (microscopic, mesoscopic and macroscopic). In a microscopic modeling, each vehicle movement is evaluated individually according to interactions with other vehicles movement and traffic system. Also, all vehicles are moved through the network of transportation facilities by split-second basis according to the physical characteristics of the vehicle (length, maximum acceleration rate etc.), the fundamental rules of motion and rules of behavior (car following rules, lane changing rules, etc.) (CDOT, 2013). Macroscopic models simulate traffic flow, taking into consideration cumulative traffic stream characteristics (speed, flow, and density) and their relationships to each other (CDOT, 2013). Mesoscopic models combine the properties of both microscopic and macroscopic simulation models. These models simulate individual vehicles but describe their activities and interactions based on aggregate (macroscopic) relationships (CDOT, 2013).
The importance of microsimulation software has been growing rapidly during the last decades. Microscopic simulation software's are frequently used to model the stochastic process of human and driver behavior, design freeways, urban roads, and test scenario are on a whole or partial roadway network. There are many traffic microsimulation software on the market. Each software offers different properties and price to users.
CORSIM (CDOT, 2013) is one of the popular microscopic traffic simulation programs widely used by transportation professionals. CORSIM is able of simultaneously modeling surface street and freeway. CORSIM provides the user with a wealth of output data detailing several system-wide, as well as link-specific, performance measure (McTrans, 2009). The output of CORSIM is an MOE (Measure Of Effectiveness) file. It is processed into tables that summarize the information. For freeway models, the key metrics produced are flow, speed and density. The data for arterial models include throughput flows, control delays and maximum queues (Olariu and Weigle, 2009). CORSIM does not generate outputs in metric. The traffic state variables such as average speed, density, and flows are not offered directly a tabular format, even if they are written an output file. Also, it does not have an interface to directly simulate control measure such as Variable Speed Limits (VSL). TSIS provides a mechanism by which an external application can interface directly with the CORSIM simulation tool. This type of application has become known as a CORSIM Run-Time Extension (RTE) (McTrans, 2008). CORSIM offers users an RTE interface that they can use in their analysis and dynamic control study by creating their own output.

The study includes calibration of CORSIM for a vehicle segment and how to evaluate calibration results under different random distribution such as Normal and Erlang. The freeway used for the data structure is a 2.5 km stretch of O1 Freeway in Istanbul which was modeled and calibrated in CORSIM (Figure 1). The study segment has three entry (origin) nodes and one exit (destination) node. Congestion occurs during evening rush hours in the direction from Europe to the Anatolian side. Geometrical irregularities are available such as a horizontal curve and a bottleneck.

2. CORSIM

Urban traffic control center (UTCS Urban Traffic Control System-1), started with the development of CORSIM in the 1970s. Later the project transformed into NETSIM in order to simulate urban roads. After a while, the development of microscopic simulation software for freeway simulation, FRESIM, continued with a simulation model. Finally, NETSIM and FRESIM have been integrated into a simulation program called CORSIM. FHWA has placed CORSIM into its user-friendly interface named TSIS (Traffic Software Integrated System). McTrans Center is the current developer, maintainer, and supporter for CORSIM which is a part of The University of Florida (McHale et al., 2002)
Users can model any type of networks such as freeway, urban roads or integrated network and apply some traffic control tools with CORSIM. CORSIM can simulate traffic flow vehicle basis. TSIS also includes TRAFED and TRAVFU modules. TRAFED provides a graphical network interface to input network geometry and a tool transforms the graphical network into CORSIM input file. TRAVFU module is off-line visualizing environment depicts vehicle movement and measure of estimation data (MOE). MOE data can be watched in tabular or graphic format, but the module does not support extracting them.
CORSIM models the traffic system as the interaction of the roadway, detectors, traffic control devices, and vehicles; each of which has their own set of attributes (Owen, 2001). CORSIM evaluate vehicle moving on a network by supervising the interacting of the vehicle with other vehicles, traffic control tools, and road geometry.

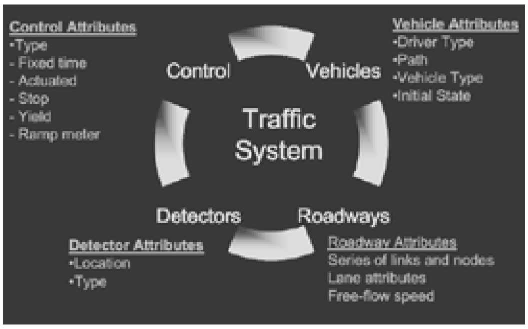

Fig. 2.
CORSIM Attributes
Source: (Owen, 2001)

These properties are seen in Figure 2. CORSIM offers a test of traffic operating scenario, signal control, geometric design proposals, incident management, ramp-metering control and private lanes. CORSIM needs four important steps like other traffic microsimulation software's. These are data collection, describing network in software, calibration, and validation.
Data collection is the most difficult and expensive process. It covers an array of selections. These selections are observation point location, data collection method (manually or automatic), equipment (video camera or other

surveillance equipment such as loop detectors or radar detectors), etc. Collected data should include volume, speed, the geometric dimension of roads (lane width, lane, acceleration, deceleration lane length), and free flow speeds. Besides, there are many predefined parameters in CORSIM. These parameters cover driver behavior, vehicle performance, and road characteristics having default values reflecting average conditions. It is not recommended to change default parameters without important exceptions. Depending on the traffic conditions for a specific scenario it is possible to change the default characteristics.
Each vehicle's location and speed on a network is updated every second based on vehicle performance and driver behavior characteristics, lane changing/car following logic and roadway traffic control signals (Wang, 2008). The interaction of vehicles with other vehicles, traffic control devices, and roadway geometry are modeled.

2.1. CORSIM Modelling and Calibration

For the case study, 2.5 km of the freeway section belongs to O1 Freeway in Istanbul (Figure 4) was modeled and calibrated before creating RTE module in CORSIM. TSIS 6.1 software package was used for modeling of the sample network which has two ramps.

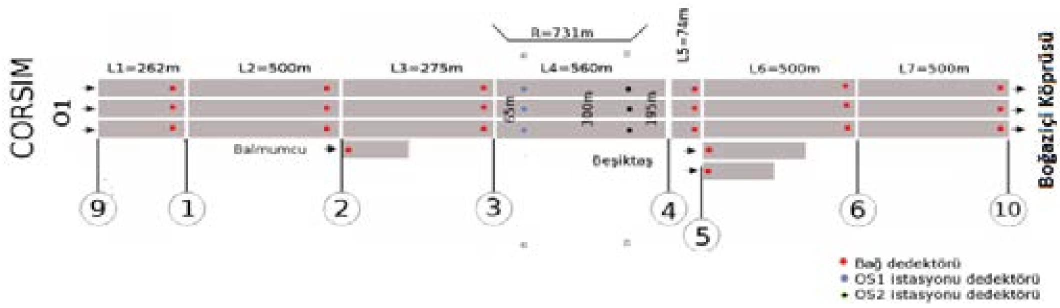

Fig. 3.
Road Geometry and Detectors Location
Sources:(Demir, 2012)

Traffic congestion, shock waves, and queues occurred on the section in rush hours. As part of the way for the creation of the CORSIM simulation model, the road was coded into the CORSIM network format by the aid of the maps (Google Earth and Istanbul Municipality Maps). The geometry of the working area which was composed of TRAFED is shown in Figure 4. Traffic volume data are obtained by video recording for modeling and calibration of the CORSIM model. The record was taken from 16:23 to 17:27 for evening peak period, on 16 October 2007. Then for examining the records, observation stations (Figure 4 represents OS1 and OS2 detector locations on the working zone.) were set using the maps and on-site measurement by GPS devices. Speed and volume data were measured in the one-minute interval. Traffic state variables speed, density, and flow were calculated from counts conducted at these stations. After inputting observed demand values and driver's properties and vehicle performances, CORSIM was calibrated for 65 minutes. The saturation warm-up option was chosen as a warm period. Calibration was confirmed by Theil's test comparing observed speed and flow with CORSIM outputs at two observation stations.

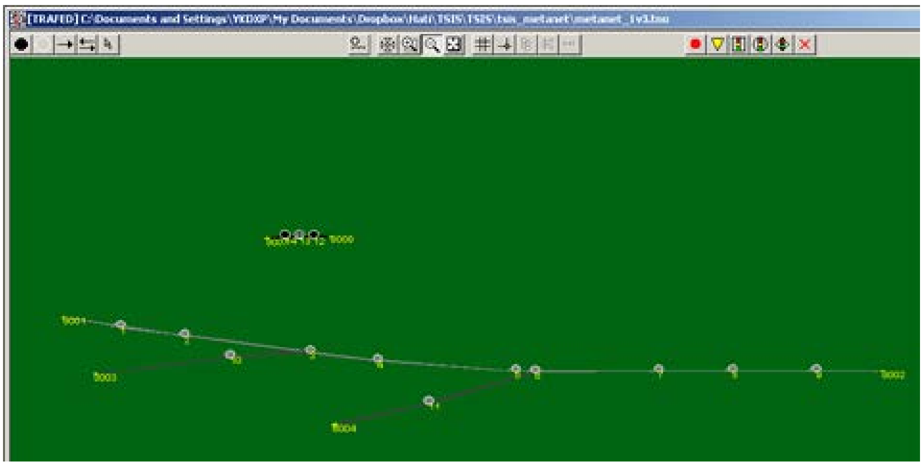

Fig. 4.
The Working Area composed by TRAFED

Theil's *U* statistic is a relative accuracy measure that compares observed flows and speed with the results of the simulation results. It also squares the deviations to give more weight to large errors and to exaggerate errors, which can help eliminate methods with large errors

$$U = \sqrt{\frac{\sum_{t=1}^{n-1}\left(\frac{\hat{Y}_{t+1} - Y_{t+1}}{Y_t}\right)^2}{\sum_{t=1}^{n-1}\left(\frac{Y_{t+1} - Y_t}{Y_t}\right)^2}} \tag{1}$$

where Y_t is the observed value of a point for a given time period t, n is the number of data, and $\hat{Y}_t$ is simulation forecasting. If U is less than 1 it means the forecasting technique is better than guessing. If U is equals to 1, the forecasting technique is about as good as guessing. If U is more than 1, the forecasting technique is worse than guessing.
Theil's statistics for average speeds (mean speed graphics Figure 5) and flows (flows graphics Figure 6) were calculated at 0.07 and 0.08 respectively at both stations (Demir, 2012).
CORSIM completes a simulation along a timeline including time intervals which is called "call points". There are six main call points and some of them have sub-call-points. These are;

1. Initialize;
2. Begin simulation (startup);
3. Time step complete;
4. Time interval complete (end of each time specified by the user - *end of 10s in the study*);
5. Time period complete (end of the time period specified by the user - *after 5 minutes in the study*);
6. Simulation Complete - *4500s in the study.*

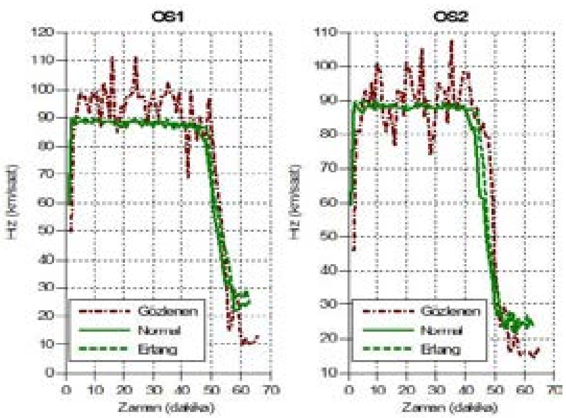

Fig. 1.
Mean Speeds

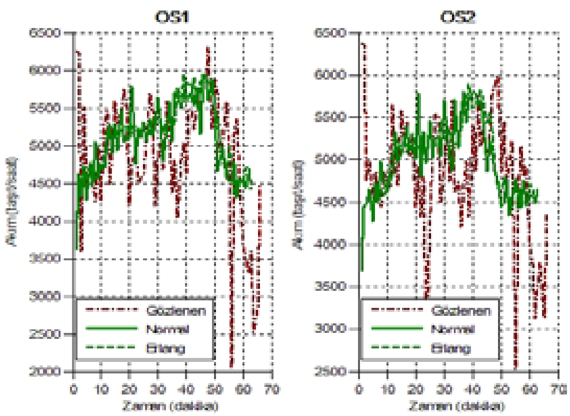

Fig. 2.
Flows

Any custom RTE function should be assigned one of these points. Functions are executed one or more times by CORSIM depending on selected time steps.

3. Conclusion

Evaluation of calibration results is given below.
OS1 Speed: The observed speed is more compatible with the Erlang distribution results. The mean error of normal distribution and Erlang are 4.61 and 2.65 respectively so that Erlang distribution has a lower error in the speed prediction. On the other hand, when you look at the error sign, both for the distribution of observed (on average) of lower CORSIM speed values produced can be seen. When looking at the average absolute error, two distribution have close values with respect to each other. Mean absolute percentage error has two similar values in the distribution. The *U* statistic, which measures the success rate of CORSIM's time series as it produces observations, approaches zero for both distributions. This means that CORSIM has successfully produced the observed speeds in the working segment. Having Erlang distribution lower error than the normal distribution point that Erlang is more suitable for modeling the working section.
OS1-Current: The values of the measurements obtained in the tests made for both distributions are very close to each other. The mean error measure for both distributions is negative. This shows that CORSIM estimates the current values at a higher average than the observations. Observations show sudden changes in the current graph which causes this (Fig. 5). When we look at the average absolute error percentage, it can be seen that CORSIM estimates the current values proportionally with a lower error rate. For both distributions, the *U* statistic has the same values and the near zero value.
Os2 Speeds: In general, the error values of this station are lower than the error values in the OS1 monitoring station, and the Erlang distribution, as in OS1, has lower error values than the normal distribution in terms of unbiased and unbiased error values.

OS2 Flow: All test criteria for both distributions have close values. *U* (0.08) shows that the current values of this station can be successfully represented by CORSIM for both distributions.
As a result of the calibration, the selected traffic behavior can be successfully represented by CORSIM according to the test criteria. The Erlang distribution seems to be particularly successful in modeling speeds. For this reason, the Erlang distribution is more suitable for simulations. With the help of calibrated CORSIM, the traffic control methods can be being applied to the working segment and the reaction that the traffic may be predicted. It is thus possible to test the validity of the work in the laboratory environment before applying for the work.

A BICRITERIA APPROACH FOR ORDER PICKING OPTIMIZATION PROBLEM IN WAREHOUSE

Daniel Kubek[1], **Paweł Więcek**[2]
[1,2] Department of Transportation Systems, Cracow University of Technology, Poland

Abstract: Warehouse is a key element of logistics networks, regardless of the functions it performs. The efficient functioning of the storage process can significantly affect the efficiency of material flows throughout the entire logistics chain. The order picking process is an extremely important part of the warehouse process and its one of the most cost-intensive operations. It is estimated that the cost of order picking represents about 55% of the total warehouse operating costs. The main target of the paper is to present a bi-criteria picking routes optimization problem considering goods susceptibility stacking on picking device, expressed by products weight classes. The proposed model aims at minimizing the total travelling time and the picking time of handling activities during the picking process. The presented approach has been verified throughout a numerical example based on real data from the warehouse with manual picking order process. Additionally, an analysis of optimal Pareto solutions has been performed and the potential benefits of a multi-criteria approach in the considered issue highlighted.

Keywords: the travelling salesman problem, pick path optimization, order picking an optimization.

1. Introduction

The storage process is a very important part of most logistics systems. Its main purpose is storage and buffering of products, from raw materials and parts, finally to finished goods at any nodal point in logistics network. Therefore a pressure to increase a warehouse performance among the logistics chain actors has grown in recent years due to many reasons. For example the rapid growth of the number of on–line shopping and retailer transactions, globalization, greater amount of logistics providers, orders managed directly by the warehouse, require warehouse quicker time response to meet customer high expectations and forces to handle a large number of orders (Davarzani & Norrman, 2015; Gong & De Koster, 2008; Merchet et al., 2015). Among the many warehouse operations, the picking process is one of the most time-consuming and labour-intensive, especially in warehouses with a low degree of automation. Order picking is defined as the process of retrieving products from storage (or buffer areas) in response to a specific customer request. It is estimated that the order picking process is responsible for 55 – 75 percent of warehouse total operation costs (Chang et al., 2011). The order picking activities are especially important in manual picker to parts picking system, where the order picker walks or drives along the warehouse's aisles with a picking device to collect the requested goods from proper locations. This type of system is still most common from all order picking systems in Europe (De Koster et al., 2007). In general, two types of picker-to parts systems can be distinguished: low-level picking and high-level picking. According to first one, the order picker picks the items from storage racks or bins travelling along the storage aisles, while the second system uses high storage racks and order picker uses a lifting order-pick truck or crane. An alternative approach is the parts of the picker system based on the use of automatic storage and retrieval cranes. Decisions in the context of the picking process optimization and control can be divided into three areas: storage policy, order consolidation policy, and routing policy. These usually relate to tactical and operational level characterized by different time horizon (Rouwenhorst et al., 2000). Respectively they concern the following issues: shape, layout design, selection and dimensioning of the storage system (tactical level), products assignment to proper locations in storage zone (tactical and operational level), assigning orders to pick batches and grouping aisles into work zones (batching and zoning) (tactical and operational level), order picker routing (routing) (operational level), sorting picked units per order and grouping (operational level) (De Koster et al., 2007). All of these issues are interrelated and determine the effectiveness of the order picking process. Since last decades many authors dealt with the above issues both separately and by trying to combine several planning problems into one optimization model as well as approaches in which they were solved sequentially in order to increase the efficiency and reliability of the picking process (Celik et al., 2014; Valle et al., 2017). Of the many publications considering the order picking planning, a significant part focuses on the picking routes optimization using both accurate and heuristic methods, as well as different routing strategies (for example S-shape, Return, Mid-point and Largest gap strategy). The picking process consists of several operations. First, a picking order is composed for which a setup time is needed. After then the order picker starts travelling to the proper storage locations, search and pick required items. In some cases (orders split across zones or batches) orders are additionally sorted and consolidated before shipping (Dekker et al., 2004). Among them, travelling time is the crucial component and responsible for more than 50 per cent of the total order picking (Tompkins, 2010). Accordingly, the order picking time consist of many time-consuming operations like setup time, travel time, search and pick a time, waiting time, sorting time and others (Gils et al., 2018). Such activities may include, inter alia certain transhipment operations on the picking device due to the specific characteristics of the products, e.g. different products weight classes, which can significantly increase the picking time. Therefore, in order to improve the performance of the order picking process, the key element is to reduce the travel time and minimization of handling operations. Most of the articles focus on distance and travel time minimization by picking routes optimization, storage location assignment as well as order batching policies (Scholz & Wäscher, 2017; Scholz et al., 2016; Zhang et al., 2017; Theys et al., 2010;

[1] Corresponding author: dkubek@pk.edu.pl

Hong et al., 2017). Additional performance measures taken into account in the problem are related to tardiness rate of order picking, service level or labor optimization (Henn, 2015; Gong & De Koster, 2008; Hsieh, & Huang, 2011; Quader, & Villar, 2016) Despite of many studies the problem of considering the products characteristics especially the product's weight class is still underestimated . However, in publications, it is difficult to find a solution for routing problem respecting product's weight (Chan & Chan, 2011). Therefore the proposed in the paper approach consider, in addition to the travelling time, the minimisation of the transshipments number due to a product weight conflict as a result of the assignment to different classes.

2. Problem Description and Mathematical Formulation

The model for bicriteria order picking optimization problem (OPOP) can be presented using the graph theory, where it is assumed that: there is a directed graph **G** = <**V**,**A**>, where **V** = {0,1,2,…,n} is the set of vertices (it represents the storage picking locations), and **A** = {(i,j): i^j**V**, i≠j} is the set of directed graph arcs. The vertice V={0} is the input/output point for storage. To each arc (i,j) from the set **A** assigned were weights: travel time **T**={t_{ij}: ∀(i,j)∈**A**}. It is assumed that the travel time is calculated by using the shortest path problem between a pair of locations in the warehouse. In every picking location, the product with the specified amount and weight class is stored. The amount of product is formulated by **S** = {s_i≥0: i∈**V**}; the weight class is noted as **P** = {p_i≥0: i∈**V**}. The highest weight class, the higher product susceptibility to damage is, hence the product should be on the top of on picking device. There are the following variables in the model: **X**={x_{ij} ∈{0,1}, ∀(i,j) ∈**A**}, which means whether the arc (i,j) is in the picking route. This assumption is similar to popular integer formulation of well known travelling salesman problem. The quantity of the stored product and device unit capacity is omitted. This assumption describes the decision process where the assignment problem of picking products to devices is the upper-level decision process to the OPOP in the warehouse.
The aim of OPOP is to find the optimal solution including two criteria:

- the minimization of picking travel time,
- minimization of the penalty for handling activities related to the product weight class.

The first criterion f_1>0 relates to travelling time from input/output point to first storage picking location, between the storage picking locations, and back to the input/output point from the last storage picking location. It could be formulated as:

$$f_1 = \sum_j^n \sum_i^n x_{ij} \cdot t_{ij} \qquad (1)$$

The second criterion f_2>0 based on a differential matrix of weight product classes. It is described indirectly the picking time and the handling activities, such as products reloading on picking device, which is related to the weight class of the products. Any misstatement in picking order led to increasing the picking time. Hence, it is assumed, that any nonoptimal picking order (different solution from an ideal picking order) is modelled as an extra penalty occurred in the second criterion. The ideal picking order is understood as a sequence of picking storage locations where reloading process determined by weight class of product is minimized. If the solution for picking order reaches the optimum, the penalty is not added. The penalty k_{ij} between any pair of the storage location is computed as:

$$k_{ij} = |p_i - p_j|, \forall (i,j) \in \mathbf{A} \qquad (2)$$

Considering above ve assumption, the penalty for picking order is modelled:

$$f_2 = \sum_j^n \sum_i^n x_{ij} \cdot k_{ij} \qquad (3)$$

The aim of the second criterion formulation is not to increase the complexity of the proposed model. Basing on popular mixed integer approach for routing part of OPOP, a mathematical formulation for products reloading process on picking device could bring nonlinearity in the model. It is due to two main issues. Firstly, to model directly the packing/repacking process, it is necessary to create a new continuous variable, which describes the commodity flow during the routing process in the warehouse. Secondly, by the multiplication of two variables, because the handling activities depend on picking point sequence (the variable x_{ij}) and depends on the quantity of handling commodity (the commodity flow variable). Hence, having regard to the NP-hard nature of the TSP formulation, it is not recommended to increase the complexity of the proposed model. As is shown in further part of the paper, proposed formulation (equation (2) and (3)) gives a quite good approximation of real process of the handling activities, which are related to the weight class of the products.
Considering the above assumption and problem specification, the OPOP is formulated as:

$$(OPOP): \quad \min_{f_1,f_2}\left[w_1 \cdot \frac{f_1 - F_1^{min}}{F_1^{max} - F_1^{min}} + w_2 \cdot \frac{f_2 - F_2^{min}}{F_2^{max} - F_2^{min}}\right] \qquad (4)$$

$$f_1 \geq \sum_{i\in V}\sum_{j\in V} x_{ij} \cdot t_{ij} \qquad (5)$$

$$f_2 \geq \sum_{i\in V}\sum_{j\in V} x_{ij} \cdot k_{ij} \qquad (6)$$

$$\sum_{i=1}^{2} w_i = 1 \qquad (7)$$

$$\sum_{i\in V} x_{ij} = 1, \quad \forall j \in \mathbf{V} \qquad (8)$$

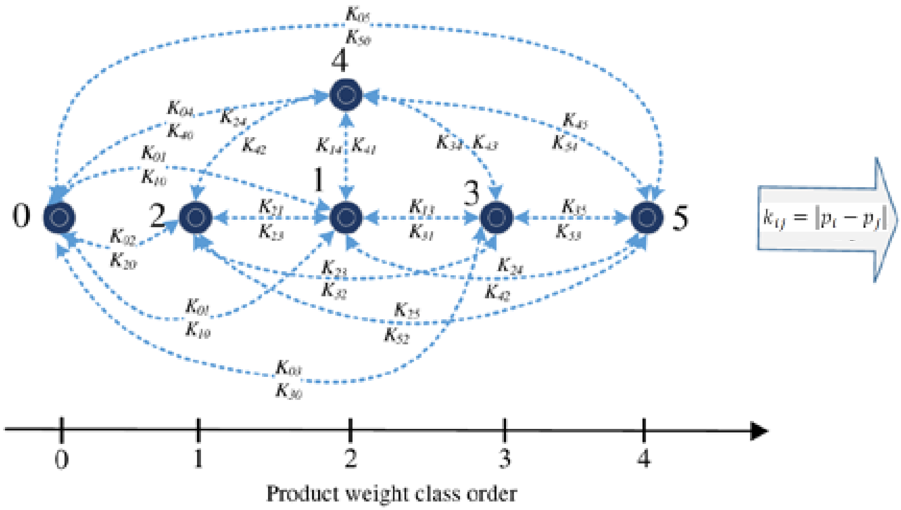
$$\sum_{j\in V} x_{ij} = 1, \quad \forall i \in \mathbf{V} \qquad (9)$$

$$u_i - u_j + 1 \leq (n-1)\cdot(1 - x_{ij}), \quad \forall i \in \mathbf{V} \setminus \{0\} \wedge \forall j \in \mathbf{V}\setminus\{0\} \wedge i \neq j \qquad (10)$$

$$0 \le u_i \le n-2, \quad \forall i \in \mathbf{V}\backslash\{0\} \tag{11}$$
$$x_{ij} \in \{0,1\}, \quad \forall (i,j) \in \mathbf{A} \tag{12}$$
$$f_1, f_2 \in \mathbb{R}^+ \tag{13}$$

The criterion function (4) has been written in the normalized form. The normalization has been introduced due to the fact of adding two different criteria with varying units of measure. Parameters $\{F_1^{min}, F_1^{max}\}$ mean respectively the minimum/ maximum picking travel time in a warehouse for a given graph, and parameters $\{F_2^{min}, F_2^{max}\}$ - respectively the minimum/ maximum penalty for additional manipulation due to the improper order of picking products. The minimum value could be understood as the case where the picking order in the route is created by sorting the weight class of product, and the maximum penalty is the worst case, where almost all product pickup form storage place is associated with additional handling operation (e.g. reloading). The additional parameters $\{w_1,w_2\}$ was introduced in order to be able to assign appropriate weights to a given member of the criterion. Constraint (5) and (6) describes assumed criterions. Equation (7) ensures the convexity of the main function and the Pareto-optimality of the obtained solution. The limitations (8) and (9) correspond to flow constraints in the graph. Formulation (10) is the Miller–Tucker–Zemlin subtour elimination constraints, and (11) help to give precise meaning to each additional variable u_i. Rest of the constraints define the nature of variables.

For clarify the concept of second criterion approximation, let consider the illustrative example. Let assume that problem contains 5 pickup location in warehouse: **V**={0,1,2,3,4,5} and its corresponding product weight class: **P**={0,2,1,3,2,4} and product amounts: **S**={0,3,2,4,5,2}, respectively. The problem of minimization picking travel time, usually, is modelled as a directed graph, where the attributes of arcs are shortest travelling time between two storage points. The solution to such a problem is the sequence of order picking points (picking route). The concept assumes that to every arc of the graph the second attribute is added. It is the absolute difference of weight product classes between origin storage pick point and destiny storage pick point. This mechanism is described in Figure 1.



Kij	0	1	2	3	4	5
0	-	0	0	0	0	0
1	0	-	1	1	0	2
2	0	1	-	2	1	3
3	0	1	2	-	1	1
4	0	0	1	1	-	2
5	0	2	3	1	2	-

Fig. 1.
Example graph for the order picking optimization problem and its corresponding complementary differential matrix of weight product classes
Source: own elaborations

Continuing with the example (see Figure 2), if we assume that picking route: 0-2-1-4-3-5-0 is optimal only for the second criterion, using (3), the penalty for such solution will equal f_2=3 (in optimization model (OPOP) after normalization in (4) it will equal 0). Nerveless, if the solution will be determined as picking route: 0-2-1-3-4-5-0, the value of the second criterion will equal 5. Hence, that value could be interpreted as an extra penalty for improper picking order in the picking process.

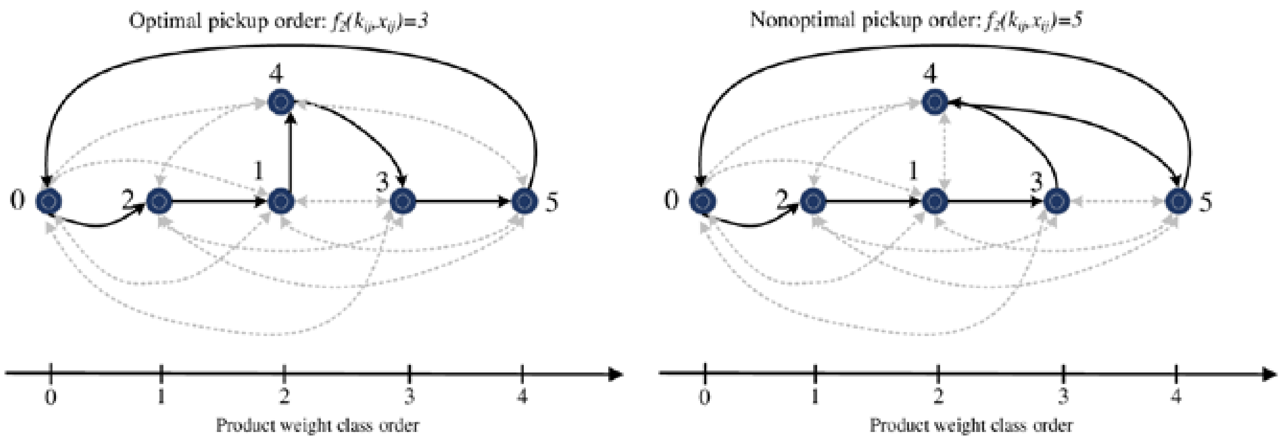


Fig. 2.
Penalty evaluation example for a non-optimal order of picking route in the warehouse
Source: own elaborations

As it was mentioned earlier, the proposed approach does not include an amount of picking product s_i and related with it picking time. However, for comparison purpose, the additional indicator $F_2^{(R)}$ was estimated. It describes the picking time of manipulation activities which have to been done by non-optimal order of picking. This time is also dependent on the amount of picked product. If we assume that mean handling time for one unit of product is 1 seconds and referring to above example, for solution presented on the Figure 2, the picking time for handling activities will equal: $F_2^{(R)}=4$ (only product from 3rd picking point has to be unloaded and loaded again on the transportation device, when the 4th products are receiving from rack). That assumption was used to further numerical experiments.

3. Characteristic of the Proposed Model

The proposed method was used for real picking lists data from the medium warehouse (2 500 m2). The warehouse layout is subsequent: number of rows of the rack in stock - 20 pieces, number of racks in a row - 43 pieces. Traveling time between storage picking point was calculated before the optimization process with assumptions of moving time between the racks: length of a single rack: 1.4 meters, single rack width of 0.9 [m], corridor width: 2.5 [m], travelling time of one meter in a straight line: 1.2 seconds and travelling time of a corner: 2 [s]. Four real testing instances were analyzed: 5, 15, 33 and 57 number of picking points (the real datasets). It also assumes that picking time for one unit of the product equals 1 second.
Based on real data sets, the stochastic characteristics of input data was retrieved (travelling times, the quantities of product in the picking process and products priority). Theoretical probability distribution and its parameters were used to generate random instances from 10 to 90 picking points at the warehouse (the simulation datasets). All solutions ware obtained in CPLEX 12.0 software and the model was optimized by an exact method with two stopping criteria: 5 minutes of computation and 1% of the absolute difference between temporary solutions in a node of the algorithm.

3.1. Simulation Datasets

Firstly, the accuracy of the second criterion approximation was examined. The aim of such simulation is to check what is the degree of relationship between the assumptions for the second criterion in the model (OPOP) and its approximation to the real value for picking time connected with handling activities. Each solution of tested instances was used to evaluate picking time caused by the non-optimal order of picking with dependence on product amount (indicator $F_2^{(R)}$). Evaluated parameters were used to estimate the Pearson correlation coefficient (PCC) and the coefficient of determination (R^2) between the model's value for second criterion and its real value for handling activities. The results are presented in Table 1.

Table 1
Pearson correlation coefficient and coefficient of determination for approximated and real value of the second criterion in the model (OPOP)

	Problem size	**10**	**20**	**30**	**40**	**50**	**60**	**70**	**80**	**90**	**Mean**

Source: own elaborations

Obtained results prove that the proposed formulation of product picking order criterion is a good quality approximation of real picking time, such loading and unloading on the transportation device. The fitness degree is related to problem size, its decrease with problem size and up to 90 picking tasks the quality is on a high level.
Next analysis concerns model utility depending on weight structure and problem size. Table 2 presents the analysis results. The complexity of the problem increases with the size of the problem, what is quite a predictable phenomenon. Optimization time depends also on the relation between the considered criteria. Model with the only minimization of handling activities is complex; hence the computation time is large. The reason is the indirect connection of the second criterion with problem constraints defining proper of flow in the graph, e.g. with subtour elimination constraints. Moreover, including in model, the minimization of picking travel time decreases the computing time up to few seconds for the largest instances. Referring to the exact method of optimization and the bi-criteria character of the problem, the obtained result is very effective. It needs to be more investigated in further research, but an explanation of such effect could be the normalized weighted construction of the main criterion. For a more excellent illustration, in Figure 3, the normalized sum of criteria and the normalized weighted sum of the criteria were presented. The assumption for that experiment was the omission of the constraint (7). The range of changeability for weight was [0;1] with 0,1 interval step. It can be observed, that weighted formulation of optimization model's criteria, transform the main criterion into the convex surface, which changes the model to be more tractable (in computing sense). Additionally, even if the computation takes the maximum time, the benefits in operational field compensates the waiting time for obtaining a solution.

Table 2
Computing time depending on instances size and weight values of criteria function

		Computation time [s]

3.2. Real Data Sets

The proposed approach was tested on data from a real warehouse and detailed results are presented in Table 3 and in Figure 4. The picking time in extreme cases could be larger than the picking travelling time. This is especially observable in one criterion optimization. If the optimal value for picking time is reached, the picking travelling time is extremely large, and vice versa. Only using both criteria in optimization in the warehouse could bring the mutual benefits, which would be realized in decreasing the operational cost of storage.
Figure 4 was created in similar condition as Figure 3, the constraint (7) was omitted. It presents the Pareto set for picking travelling time and approximation of picking a time (our approach) and it corresponding Pareto set for picking a travelling time and the real value of picking time. It can be observed the similarity of both sets, which again proves the conclusion from previous simulations.

4. Conclusions and Further Research

The current dynamic specificity of the market caused by the popularity of electronic commerce, globalization, growing customers expectations referring to the quality of logistics services provided and delivery times, forces warehouses to handle a growing number of orders in shorter time windows. Thus, the order picking process is one of the key issue affecting the performance of the whole warehouse. In the paper, a bi-criteria approach to picking routes optimization problem has been presented and tested. The analyzed problem concerned a warehouse with a manual picking system. The aim of the first criterion of the proposed model was to minimize travelling time through an optimal sequence of visited collection points in the storage area. The second criterion referred to handling operations minimization connected with products transhipment on a picking device. Consequently, the second criterion was reduced to the shortest path problem, where the attributes on the arcs of the graph representing the considered problem were expressed by the abstract value of the differences in product's weight classes. For this purpose, a differential matrix of weight product classes has been constructed and used. The proposed model has been verified based on sets of numerical examples with the use of real picking lists from the warehouse. The calculations have been executed for a different number of picking points (from 10 to 90 picking points). In the optimization process, the two formulated criteria have been replaced by a standardized weighted sum of partial criteria. The obtained results show that a linear combination of criteria forms a convex surface which had a positive effect on the calculation time. Calculated set of non dominated Pareto solutions, indicated that the transshipment operations referring to products weight classes can significantly affect the total picking time (in some cases travelling time equals 480 s corresponds to the significant time of transshipment 3293 s). This explains the necessity of taking into account alternative product-specific criteria in the order picking optimisation process. Further studies will focus on respecting the impact of products allocation in the storage zone on the obtained final solution.

Abstract: Within the Shift2Rail-Project "GoSafeRail" so called Kronecker Algebra is applied on the railway line from Zagreb to Rijeka for traffic flow optimisation. Kronecker Algebra consists out of Kronecker Product and Kronecker Sum to describe concurrency of tasks as well as their interleavings. The railway line from Zagreb to Rijeka has been successfully modelled by software tool called OpenTrack. In this project data from OpenTrack model is automatically converted into input for Kronecker Algebra to manage railway operation in an efficient manner.

Keywords: Kronecker algebra, rail traffic flow optimization, rescheduling.

1. Introduction

One of the objectives of the Shift2Rail project Global SAFEty Management Framework for RAIL Operations is the development of an evolutionary Decision Support Tool that self-learns (evolves) based on machine learning algorithms and artificial intelligence with the main goal of offering safer, reliable and efficient rail infrastructure. Due to a low number in failures on the infrastructure network, this leads to a lack of data crucial for machine learning. This will be solved by implementation of Near-Miss Concept; in other words, low-consequence events will be also included in the model and enable use of statistically significant data for model training. Furthermore, a new train mounted multiple sensor system for Object Detection will be developed.
Moreover, with OpenTrack micro-simulation modelling tool, traffic model will be developed that will use multi-criteria optimization algorithms to address complex requirements, for both passenger and freight transport. Using Kronecker algebra, which showed good results in dealing with optimization scenarios in railway traffic flow, especially avoidance of deadlocks, simulation of the line between Zagreb and Rijeka in Croatia has been performed as well as a optimisation based on Kronecker Algebra.

2. Kronecker Algebra and its Application in Railway Operation

One of the constantly present problems in railway systems is the problem with deadlocks. Since there were no applicable solutions in the middle of 20th century, computer scientists tried to solve this problem by implementing Kronecker algebra in the analysis (Mittermayr *et al.,* 2012).
Before going into solving deadlock issue, a proper definition is needed. Stallings (2001) defines Deadlock as 'an impasse that occurs when multiple processes are waiting for the availability of a resource that will not become available because it is being held by another process that is in a similar wait state'. There are four preconditions for a deadlock to occur according to Coffman (1971); in other words, if one of these conditions is not met, there will not be a deadlock. There is a mutual exclusion, where a resource can only be used by one process at a time. Second, hold and wait includes processes already holding resources and requiring additional resources held by other processes. Third, the so called no preemetion, no other than the process itself can release the resource. Finally, the circular wait that requires at least two processes to form a circular chain in which each process waits for a resource that is being held by the previous process in the chain. Clearly, these four conditions can be applied to railway systems.
After defining conditions for deadlock occurrence, possible ways to deal with deadlocks can be identified. These are deadlock prevention, or removing one of the above mentioned conditions in order to prevent deadlock from even occurring; deadlock avoidance, or decision about resource allocation in advance; and finally, after deadlock detection, termination and restart of the process. For the railway systems, only deadlock avoidance is applicable (Mittermayr *et al.,* 2012).
Kronecker algebra is a mathematical model that consists of Kronecker Sum and Kronecker Product. For the explanation of these two operations, set of matrices (1) is defined

$$M = \{M = (mi, j)mi, j \in L\} \tag{1}$$

where$L$denotes a set of labels with$\langle L, +, 0\rangle$being a commutative monoid and$\langle L, *, 0\rangle$a monoid (Mittermayr and al., 2012). For this case, only matrices$M \in M$with o (M) referring to the order of matrix. Additionally, n-by-n (2) matrices will be used.

[1] Corresponding author: andreas.schoebel@opentrack.at

$$Z_n = (z_{i,j}) \text{ where} \forall\ i,j: z_{i,j} = 0 \tag{2}$$

Kronecker product is denoted by A □ B and results in mp-by-nq block matrix, as it can be seen in (3). Matrix A in this case being m-by-n and matrix B p-by-q matrix. As already mentioned above, Kronecker product is used for modelling synchronisation.

$$\text{A □ B} = \begin{pmatrix} a_{1,1}B & \cdots & a_{1,n}B \\ \vdots & \ddots & \vdots \\ a_{m,1}B & \cdots & a_{m,n}B \end{pmatrix} \tag{3}$$

Kronecker sum of matrices A of order m and matrix B of order n, denoted by A □ B (4), is a matrix of order mn defined by

$$\text{A □ B = A □□} I_n + I_m \text{ □□B} \tag{4}$$

where Im and In (n-by-n matrix with ones on the main diagonal and zeros elsewhere) denote identity matrices of order m and r, respectively.

Application of Kronecker algebra in optimization of railway traffic flow lies in its functionality to detect and avoid any deadlocks within the whole analysed railway system, not just on one section. To put it differently, it can is represented as a matrix that includes all possible train movements in a system. In other words, deadlock-free solutions are overall best calculated solutions that take schedules, delays and different types of restriction on the tracks into account (Volcic, 2014). Whereas Kronecker Sum calculates all possible interleavings of all trains not using the same track section, Kronecker Product ensures that those using common track sections can sequentially enter only free sections, namely, sections previously released by another train. Kronecker Algebra delivers results as a matrix. However, these can be represented as a graph, especially time-speed diagram.

3. Data Converter from OpenTrack into Kronecker

Starting with the OpenTrack model of a railway line, two files are generated and exported using existing filters. Based on the itinerary covering the main track from first to last station of an OpenTrack model, a text file in so called IVT format is generated. The structure of an IVT file is always the same and contains the following information:

- position;
- vertex name up;
- vertex name down;
- vertex km up;
- vertex km down;
- speed up 1;
- speed up 2;
- speed up 3;
- speed up 4;
- speed down 1;
- speed down 2;
- speed down 3;
- speed down 4;
- gradient;
- radius;
- tunnel type;
- signal up;
- signal down;
- station name.

The four speed limits have their origin in the Swiss regulation for track speed limits for passenger, cargo (two braking settings) and tilting trains. This file in IVT format is used to create the so called tracks.csv file for Kronecker Algebra. The content of tracks.csv is:

- edge ID;
- initial condition for semaphore;
- maximum valu of semaphore;
- start;
- end;

- sigh position for start;
- release position for end;
- sight position for end;
- release position for start.

Here, the macroscopic structure of a railway line is defined. In addition, there is a micro tracks file for the description of the microscopic structure, including gradients and speed limits. This input is required for the calculation of running times later on. The timetable is exported as a text file in OpenTrack format which has the following structure:
- course ID;
- interval course ID;
- time to interval reference;
- station index;
- station sign;
- track name;
- arrival time day offset;
- arrival time;
- departure time day offset;
- departure time;
- use departure time ;
- dwell;
- stop at station;
- mean delay;
- distribution;
- delta mass.

Based on this information about the timetable of all trains running in a project, for each train a text file trainID.csv is generated as input for Kronecker with this structure:
- start node ID;
- end node ID;
- direction;
- arrival day;
- arrival month;
- arrival year;
- arrival hour;
- arrival minute;
- arrival second;
- departure day;
- departure month;
- departure year;
- departure hour;
- departure minute;
- departure second;
- stopping point;
- time integer;
- virtual stop;
- Kronecker operation (block "p" or release "v).

Additionally, train movements are calculated in accordance with their tractive-effort and braking characteristics:
- train ID;
- Kronecker train ID;
- mass engine;
- mass trailer;
- train length;
- number of trailers;
- train type;
- maximum speed of train;
- factor for recuperation;
- minimum position of train;
- maximum position of train.

4. Use Case of Croatian Railways

Within GoSafeRail project the railway line from Zagreb to Rijeka has been selected. As a first approach, the edges for the Kronecker algorithm were created between signals, speed changes and gradient changes. With this ruleset, the resulting number of edges was 1067 for the Zagreb Rijeka line, which was a fairly high amount for the Kronecker algorithm. In order to reduce execution time of the Kronecker algorithm, the infrastructure was partitioned in a macroscopic view (tracks.csv) and a microscopic view (tracks-micro.csv). For the macroscopic view, edges where only created from signal to signal. With this measure, the number of edges for the Zagreb Rijeka line was cut down to 250. Figure 1 depicts the result of this reduction, reimported into OpenTrack via IVT input.

Fig.1.
Reimported Graph of Zagreb-Rijeka Line

Another major aim in building the infrastructure for Kronecker was the simplest possible representation of the stations. The o2k converter takes care of this by producing only one edge per station, which receives the number of available tracks at this station as the maximum value for its semaphore.
After creating the infrastructure, the second step includes the production of all train course data files required for Kronecker operation by the o2k converter. OpenTrack's timetable data gives information about the passing location of the individual train. If corresponding data is available, time passes from the timetable are used as so-called measure points for Kronecker optimization. Train course files for Kronecker must reserve and free edges in a proper sequence. Especially at stations where a train should stop, the pattern for reserving and freeing edges seems to be somewhat complicated. The screenshot shown in figure 2 of a train course file generated by the o2k converter is presented in order to clarify what the proper solution to this problem shall look like.

Fig.2.
Sample Snipped of a Train Course File with a Real Stop at Station Duga-Resa

The lines starting with a hash mark (#) are comments and will be ignored by the input parser of the Kronecker implementation. These comments have proved to be useful for finding errors contained in the original data from OpenTrack, which has been entered by manually and thus may be erroneous.
For this explanation, lines will always be called by the number at their beginning. Line 172 shows a real stop taking place. Real stops contain the code 10 or 20 at the third field, depending on this course's direction: 10 is for the up direction, 20 is for the down direction. The direction is set by the itinerary of the original IVT file from OpenTrack.
The last column of each line contains a P or V operation for a given edge of the Kronecker infrastructure, which can be found in the tracks.csv file. Following common naming conventions, P is used for reserving an edge and V is used for freeing an edge.

At line 172 in this example, a stop takes place when reserving edge 163. Consulting the generated infrastructure file tracks.csv for the Zagreb Rijeka line, it can be seen that edge 163 is the station area of Duga-Resa with a maximum semaphore value of 3, meaning that there are three tracks in Duga-Resa which can be used for halting trains or overtaking stopped trains.
Line 173 shows the next operation which takes place after the train has stopped at Duga-Resa. This operation is of high importance for Kronecker algorithm. The train arrives via the edges 167, 166, 165, 164 until it halts at edge 163. The edges 167, 166 and 165 are freed in the lines 169 to 171 as can be seen in the sample snipped above. This always happens as a preparation prior to a stop and is called a "flush" in terms of the o2k converter. The edge 164 must not be freed before the train stops at edge 163, but must be freed immediately after. The o2k converter takes care of this.
When a train arrives at its final station, the codes 100 or 200 are used for the third column. As mentioned above, prior to a real stop, a flush is conducted for all but the last edges. Similarly, the last edge before the stop is freed immediately after the stop. The station edge, where the real stop itself is performed, will be freed five minutes after the stop has occurred.
Table 1 compares results from simulation in OpenTrack of all 57 daily passenger trains using the entire or parts of the Zagreb-Rijeka line with calculated delays by Kronecker. While trains arrive earlier in OpenTrack simulation, delays are reduced by application of Kronecker. Further investigations will be carried out on the level of each single train run to validate the calculations of Kronecker by simulations of OpenTrack. Thereby, the recommendations from Kronecker can be used as input for the actual performance of each single train.

Table 1
Overview on Delays in Seconds Calculated by Kronecker and Simulated in OpenTrack

	Earliness in OpenTrack	**Earliness in Kronecker**	**Delays in OpenTrack**	**Delays in Kronecker**
Sum	-3143	-2395	1407	990
Number of trains	42	33	14	23
Average	-75	-73	101	43

Source: www.gosaferail.eu

5. Conclusion

OpenTrack, being a sophisticated micro-simulation model allows the determination of impact of safety decisions on operational network performance. Thus, by incorporating both infrastructure asset (e.g. crossings, tracks, bridges, tunnels) and traffic (e.g. vehicle, freight and passenger movement), effective delivery of maintenance or new works while maximising the connectivity and adaptability of the overall surface system will be enabled. As a performance indicator for Kronecker Algebra the delays of trains at their final station are used as a benchmark criteria. First test runs on the railway line from Zagreb to Rijeka show at least a reduction of delay of 30 %.

METHODS FOR EVALUATION OF BUSINESS CONTINUITY MANAGEMENT SYSTEM IN TRANSPORT

Dana Rozová[1], Martin Šustr[2], Alena Alwicker[3], Matěj Pluhař[4]
[1,2,3,4] The University of Pardubice, Jan Perner Transport Faculty; Studentská 95, Pardubice, Czech Republic

Abstract: The proactive approach is necessary to reach the essential goals in the area of transport resilience. One option to improve the plan during crisis is the implementation of the Business Continuity Management System. This can improve planning of transport services during the crisis situation in the affected area. The level of efficiency depends predominantly on which evaluation method is used. During the selection of the method for business continuity is important to take into account the fact that this method must cover all the aspects of activities, must be easy to understand to evaluators and last but not least this method must provide the required outputs for evaluation. It is advisable that this method allows to use outputs for further use and further evaluation.

Keywords: resilience, transport, BCMS (Business Continuity Management system), evaluation.

1. Introduction

This paper follows up the paper "Business Continuity Management in the Transport". The previous paper introduced analysis describing and synthesizing realization of the Continuity System in the Transport Branch. In this paper we concluded that BCMS can be characterized at a certain time by its CCB capacity. It determines BCMS ability to absorb inactivity in demanded activities and the size of which can be affected by individual activities. Individual activity can be evaluated by the determined criteria.

2. Multicriterial Evaluation of Activities Continuity

Business Continuity Assessment is a typical task of multi-criteria assessment. The evaluation uses expert-level input data. It is therefore important that the method itself is in the most comprehensible form understandable to the evaluator. The aim of the expert assessment of the continuity evaluation is to maximize the consensus of the experts, but also to get as many original expert opinions as possible. Although expert methods can also be used to work with groups of experts (so-called group methods), expert methods for working with individual experts (so-called individual methods) seem more appropriate in assessing the continuity of activities.

It is advisable to obtain the expert opinions of the evaluation of the continuity of activities in several stages. In the first stage, the steering group will be assembled and the head of the group will be appointed. The rights and obligations of individual group members will be defined. In the second stage, the scope for the preparation for the survey itself will be proposed. In the third stage, specific experts will be identified. In the fourth stage the respective expert estimates will be proposed. Here, the experts will learn about the subject and purpose of the expertise, they will receive the information about the problem, the basic approaches to its solution and the planned course of expertise. It is then possible to obtain their assessments for processing. We can assume that the individuals (experts) are influenced by different motives, needs and interests and will be therefore subjective in their testimonies, while keeping the overall objectivity of evaluation during the survey, there is no direct communication between experts allowed.

From the analysis we can see that the input values of BCMS are vague and therefore we have to use to solve this problem the theory of fuzzy sets and fuzzy logic. In contrast to common quantification procedures, the fuzzy logic and its sets are variable and capable of working with variable intermediate values. Unlike sharp sets that have clearly defined ranges of values, fuzzy sets have these ranges variable. Since fuzzy theory is attempting to cover the reality in its inaccuracy and uncertainty (2) and furthermore, given the nature and complexity of BCMS, BCMS assessment using fuzzy logic evaluation system is a possible solution.

3. Evaluation Criteria

The choice of criteria relevant to the evaluation have affects the outcome. Individual activities can be evaluated according to the monitored parameters. Partial values can be used for the overall evaluation of the department, section or enterprise.

Creating a purposeful set of criteria for the continuity assessment of activities is an important step that can significantly influence the final results. The specified set of evaluation criteria should therefore meet certain requirements. The set of criteria should be such as to allow assessment of all significant long-term and short-term, both positive and negative, direct and indirect impacts. Each criterion must be clearly and conclusively defined. Furthermore it must be also defined the way it is going to be measured. Each aspect should only come into the evaluation once, the criteria should not overlap. It is most important to choose the correct number of criteria (properties). Too many features can make it difficult or even impossible to find solutions. If there is too few of them, there is a risk of omitting some important aspects vital for valid evaluation. It is therefore essential to find a sufficient number of characteristics with sufficient

[2] Corresponding author: martin.sustr@student.upce.cz

information and discernment. The rationality of creating assessment criteria depends on the thorough knowledge of the assessed object, on the structural as well as functional system of understanding.
The system analysis shows that the partial value of the continuity h activity depends on the questions:

- how much it can be done in extraordinary event (e. g. crisis events);
- how long the activity being evaluated does not have to be carried out without the consequent problems;
- how many activities are interconnected with the disturbing activities;
- it is possible to replace the activity, if this activity can be performed by another worker or at another workplace;
- how much is required the specialization of resources for activity;
- there are effective measures, steps or practices addressing risk reduction.

To assess the continuity of activities, 6 basic criteria are proposed, which are relevant to the previous concerns. Table 1 lists the individual criteria for with their label.

Table 1
Criteria for Evaluation of Activities Continuity

Criterion Name	Label
Fulfilment of Activity	p
Continuity of Activity	k
Interconnectivity of Activity	v
Reachability of Activity	d
Difficulty of Activity	n
Vulnerability of Activity	z

Source: Authors

Fulfillment of an activity p is the parameter that evaluates the overall use of the activity in any situation, both in the normal state and in crisis situations. The value of the Fulfillment of an Activity p can indicate that the activity is suitable only for a normal situation, a normal day-to-day regime without the possibility of its use in emergency situations or crisis situations. Under normal circumstances, all activities are valued equally because they meet the essential requirements for the outcome of the activity resulting from the expected benefit of performing the activity. In crisis situations, this standard expected performance requires more effort which is positively related to increasing intensity of the crisis. The value of this criterion of given activity is directly linked to individual crisis situations. For the actual evaluation of the value of the continuity of activities, a direct link to non-military crisis situations has been used.
The continuity of activity k is the very essence of continuity of activity, the basic observed parameter. It is assessed by the time lag between termination of the activity and the renewal of the performance without any subsequent problems.
The interconnectedness of the activity v indicates a number of previous and subsequent activities in general. For this evaluation, only a two-member causal chain was used in the sense of the cause (the activity under consideration) and the consequence (the amount of follow-up activities per activity evaluated). The resulting value v can then be determined by the relationship:

$$v = v_p + v_0$$

In the formula v_p stands for Interconnectivity, which tells about intra-company synergies, and it is the number of links of individual activities to other activities in the department, in the unit or in the enterprise. Second part in the formula v_0 is stands for External Link, which is the number the activity is connected to the surroundings outside of the enterprise.
The reachability of activity d is understood here as the representation of a worker who normally carries out the work by a worker from another, from another department, section, enterprise or outside the enterprise. In other words, it is about the substitution or substitutability for the worker who performs the activity and which, in the event of an emergency, would not be able to perform the activity himself. The term "reachability" was chosen from the point of view of its letter d, because letters z and n are already used for following parameters. In the short term, the job performed by one worker can be divided among other workers who perform the same work in parallel workplaces. In the long-term absence, workers cannot be overloaded, as their fatigue would negatively influenced their job performance. Therefore, it is also possible to consider the possibility of substitution of a worker who has been absent for a long time with a worker from a different workplace who would be able to perform the activity after a short period of training. In the partial evaluation of Reachability of Activity d, the required quality of representation can be expressed by the weight of the criterion, depending on whether a worker from the workplace is required (by increasing the weight of the criterion) or whether the worker can work from external sources (by reducing the weight of the criterion).
Criterion the Difficulty of activity n is characterized for this purpose as the number of workers involved for achieving this activity. If the number of people performing the activity is dropped consequently the performance is reduced and the desired result is not achieved. The value of this parameter can be extended by the financial cost, possibly space requirements for its implementation.

The Vulnerability parameter is *z* is reduced by rules, steps, or procedures. Measures to eliminate risks can only be partial or complex, depending on the degree of practice and their form.
The relationship between the criteria is also important for evaluation. It is also important to find the possible interdependencies or similarities between the various aspects of the assessment.
The basic concept for examining the relationship between two characters is their independence. The two criteria are independent if the assessment of the first one does not depend on the value achieved by the latter.
There is interconnection between Activity *p* and the continuity of activity *k*. It has its justification both in its normal state in terms of meeting its expected benefit and speed and the need for its use. It has its justification both in its normal state in terms of meeting its expected benefit and speed and the need for its use. If the activity is fulfilled even in crisis situations when the time demands for the activity are usually increased, then the period of possible interruption of the given activity should be one day at the most, in order to avoid the risk of delay. Therefore, if the *p* performance of the *p* activity is highly valued, there should not be too long interruptions, so the value of Continuity of activities *k* should be also high. Otherwise, there is a logical disproportion.
Indirectly there is also relation between the parameters of the activity Interconnectivity *v* the Fulfillment activity *p*. The low value of the activity *p* leads to the assumption of the low connectivity to the surrounding activities, in other words, the greater the demand for performing the activity, the more other activities require such an activity and the more requirements for the results of given activity. It is not a direct link with no exceptions, however the general trend the connection is significant. Therefore, it can be generally assumed that the higher the value of the Fulfillment activity *p* higher the Interconnectivity activity *v*.
The Reachability activity *d* has a direct link to the Fulfillment Activity *p*, therefore, the activity *p* can be maintained in the long-term even in crisis situations. There is also another parameter for the need for the performance of the activity. If the activity is not sustained and continuously claimed, the activity is less necessary and for this reason it is not necessary to provide substitution.
There was no immediate link between the Fulfillment Activity *p* and the Difficulty Activity *n*. Both parameters are independent of each other. However, if the number of workers carrying out the activity in normal condition is reduced to a smaller number of workers in a crisis situation, the difficulty in performing the activity will consequently increase.
If the Vulnerability of activity *z* is defined like a resulting effect of the threat elimination procedures, is quite obvious that the performance of the activity *p* is fully independent on it.
The continuity of activity *k* influences the relevance of activity *v* and vice versa. An activity that has several previous and sequential activities is clearly more required and has a higher requirement for continuity of activities *k*. The more people participate in the performance, the more difficult is to achieve the imperceptibility of such activity. Changes in the performance of the original activity can happen if the conditions change. The severity of activity *n* is therefore indirectly dependent on Continuity of activity *k*.
Indirect dependence is also between the Vulnerability of Activities *z* and the Continuity of Activities *k*, because the more the risk is eliminated, the less the activity is interrupted. It is an indirect dependence.
The link between Achievements of Activity *d* and Continuity of Activities *k* is quite obvious. The more the activity is substitutable, the less interruptible it becomes. There is a direct relationship here. On the other hand, no direct relationship has been found between the parameters of the Fulfillment activity *v* and the Difficulty activity *n*, between Interconnectivity activity *v* and Reachability activity *d*, Interconnectivity activity *v* and the Vulnerability activity *z*. If the activity is limited or stopped as a result of the negative impact, then it will disturb or fully stop the follow-up activities, respectively, their number will be limited according to their priority.
The Difficulty activity *n* has no direct relation to the Reachability activity *d*. If is possible to replace the employees with the full required number, the difficulty of the activity must remain on the same level.
The vulnerability activity *z* does not have direct effect on the Difficulty activity *n*. In the case that the substitution is full within required scope, it will fulfill given activity and thus there is no direct link between the parameters of Reachability activity d and the Vulnerability activity *z*. Table 2 shows the relationships between the criteria.

Table 2
Relation Between Criteria

	p	***k***	***v***	***d***	***n***	***z***
p	-	Direct	Direct	Direct	-	-
k	Direct	-	Direct	Direct	Indirect	Indirect

d	Direct	Direct	-	-	-	
n	-	Indirect	-	-	-	-
z	-	Indirect	-		-	-

Source: Authors

The partial value of the continuity activity can be noted as h and its magnitude is determined by the dependency of the observed continuity criteria.

4. Description of the Evaluation Procedure

Each activity is evaluated based on six criteria. Both criteria and their relationships are considerably complicated in terms of evaluation. The evaluation itself has two basic segments. The first are the measuring instruments (prepared scales), which are presented to the experts. The second segment is the experts themselves. The evaluation procedure is devoted to the creation of a measuring instrument. This was implemented in Microsoft Excel using a language-oriented fuzzy expert model.

In order to evaluate the continuity of activities, criteria are the input variables. At the beginning, these parameters must be measured. Here is the display of the measured quantities on the appropriate scale. Then the input values are converted to data. Each criterion related to a particular activity can be worded with the verbal characteristic. For this purpose we can use a 10-parts language scale complemented by language descriptions. This section is called fuzzy inference.

In Table 3, as an example, we can see an assessment of the range of Continuity of Activity *k*, which characterizes smooth performance of the activity. The maximum tolerable disruption of the activity is chosen up to one month when the crisis situation is resolved. Table 3 is the rating range for the maximum tolerable interruption of the activity.

From the logical realities, it is possible to consider and to infer further interconnections of how to deal with individual parameters. A relevant function of connectives must be assigned to partial valuation of the characteristics. The result of fuzzy inference is the fuzzy value of an individual activity criterion.

The defuzzification transforms the result of the previous fuzzy inference operation using the language assessment of the continuity of activities to the real values. The goal is to convert the fuzzy value of the output variable so as to best represent the result of the fuzzy calculation verbally. It is necessary to set the relevant terms. In defuzzification, there are language variables of the continuity of activity values defined by five terms. After assigning of evaluation terms follows the assignment of minimum and maximum values to individual terms. Table 5 lists the maximum and minimum values for each valuation of the single language terms.

Table 3
Evaluation of the Activities Continuity k

The scope Verbal characteristic in the Continuity of Activity *k*	**Point rating of the Continuity of Activity *k* (1–10)**	**Maximum tolerable time of the activity disruption**
Critical Activity	10	up to 1 hour
Semi-critical Activity	9	up to 2 hours
High Importance Activity	8	up to 3 hours
Semi-high Importance Activity	7	up to 6 hours
Important Activity	6	up to 9 hours
Semi-important Activity	5	up to 12 hours
Medium Importance activity	4	up to 1 day
Low Important Activity	3	up to 3 days
Unimportant Activity	2	up to 1 week
Insignificant Activity	1	more than 1 week (up to 1 month)

Source: Authors

In the next step, language terms are defined using truth functions. The rating "inadequate" is defined by L functions. For truthful functions of terms, sufficient, good, and very good, a function having a triangular form is used.. The term excellent have the Γ truthful function.

Table 1
Deadlines of Evaluation in the Continuity of Activity with Their Evaluation

Language valuation of continuity of activities	**min**	**max**
insufficient	0	0,3
sufficient	0,1	0,5

good	0,3	0,7
very good	0,5	0,9
excellent	0,7	1

Source: Authors

Because the partial rating of the characteristics is expressed by fuzzy numbers, the fuzzy weighted average is used to calculate the continuity activity evaluation. The resulting fuzzy number, which expresses the value of the criterion of the activity under investigation from the point of view of continuity, is assigned the appropriate weight of the criterion. The normalized weight of each criterion was calculated by modifying the Fuller method. The resulting scales then express the meaning of the criteria. The more important is perceived the criterion, the higher its weight.

5. Calculation of Continuity Evaluation

It is advisable to use the computing tool to evaluate the continuity of activities themselves. The computational tool was created in the Microsoft Excel for creation of the method. The user interface of the calculation tool has been subordinated to the Microsoft Excel environment with the need for interaction and combination of elements. For the entire evaluation, the computing tool works only through one Excel workbook, by inserting data into the unlocked cells of the respective worksheets. It is advisable to include contextual help in the calculation tool. In addition, the cells on the computational algorithm sheets that are needed for computation were hidden and locked when using the tool. Each activity evaluated is processed on one sheet of the workbook. The structure of sheets for sub-evaluations of individual activities must be the same. Criteria are evaluated in the tool using group frames and switches inserted in them for each word expression that characterizes the activity level. With the switch stored in the frame, you can always specify only one size for each awarded criterion. The data entered here is transmitted as a point in the graph, which here represents the basic features of the relevant function. Depending on the properties of the individual attributes, the appearance of the graph here uses the linear function as either increasing or decreasing. Using the point position in the graph, the fuzzy value of the criterion is determined. This is illustrated by Figure 1.

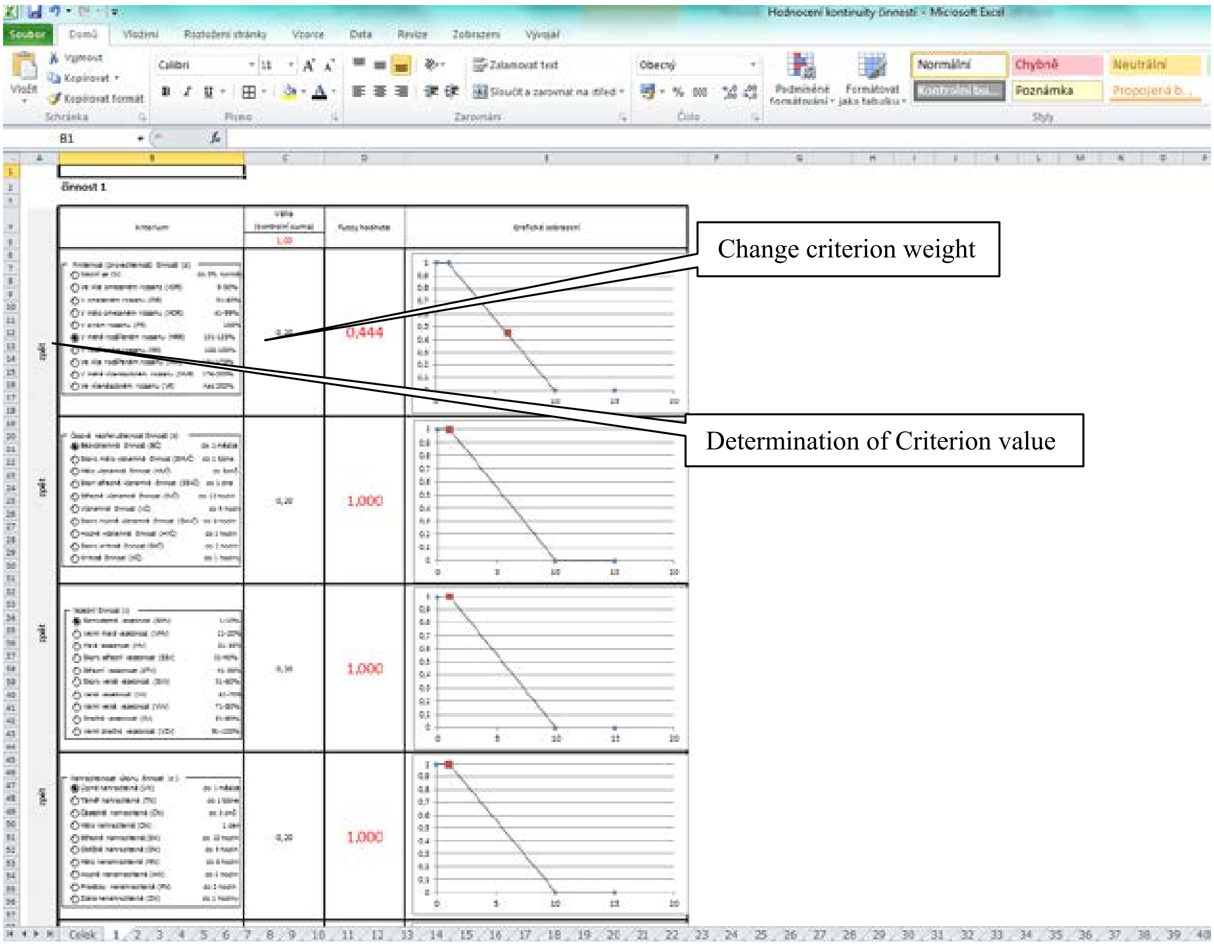

Fig. 1.
Sheet with the Valued Activity
Source: Authors

The evaluation tool itself was applied to the newly created "fuzzy" feature that extended the commonly-offered Microsoft Excel options. This is a subprogram that performs an action and returns a value. It is written to the module using formatted source code. The basic idea of function is the similarity of triangles. The two triangles are similar when they coincide at two angles. If the two triangles are similar, then the ratios of all the corresponding sides of the triangle are the same. For illustration, Figure 2 shows a graph with similarity. The fuzzy value is expressed by the y-axis, the criteria being evaluated on the x-axis.

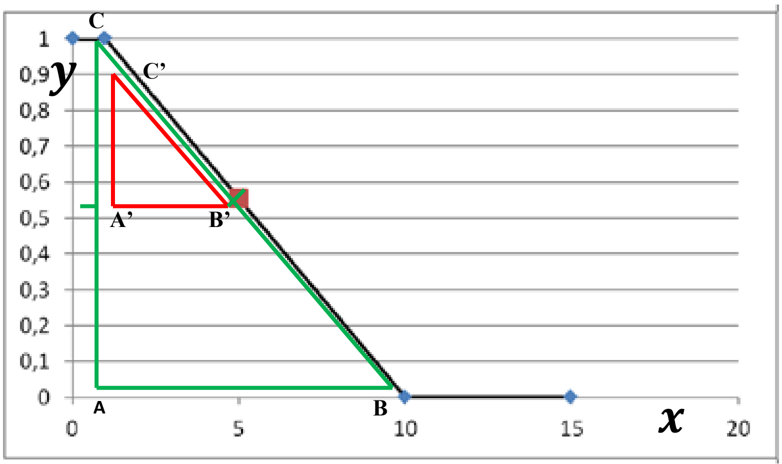

Fig. 2.
Graph of the Fuzzy Value with the Triangular Similarity
Source: Authors

The fuzzy weighted-average is used to express the overall fuzzy value of activity because the sub-criteria corresponding with the individual criteria constitute a disjoint decomposition of the overall evaluation and the partial fuzzy evaluation of the criteria expresses the fuzzy degree of fulfillment of the evaluation.
For the overall activity continuity assessment, the enumeration tool applies two newly created functions. The new "defuzzification" function combines the resulting fuzzy number of the activity being evaluated with the second table, with the language values. The function determines the percentage expression of the language value. Another new feature here used is called "rating." The function works with language valuation and the result of defuzzification. It projects a verbal and visual expression of the continuity of activities in its value form.
Experts were presented with a calculation tool that is only one workbook in a Microsoft Excel spreadsheet application. On sheet 1 "The whole" of the set, a pre-arranged list was added to complete all the titles of the evaluated activities and the overall evaluation of the whole enterprise. The first sheet of the file provides aggregate results for the entire rated area. There are four tables. In the first are the cells for the names of the entire rated object, the individual names of the activities in the object, the weight of the activities and the specific fuzzy values of the activities. For textual evaluation of the overall continuity of activities, the same calculation terms were used for both the minimum and maximum valuations as in the evaluation of individual activities. Using the resulting fuzzy value, the entire field under investigation can be evaluated and the result can be plotted graphically. Figure 3 shows the evaluation tool sheet 1.

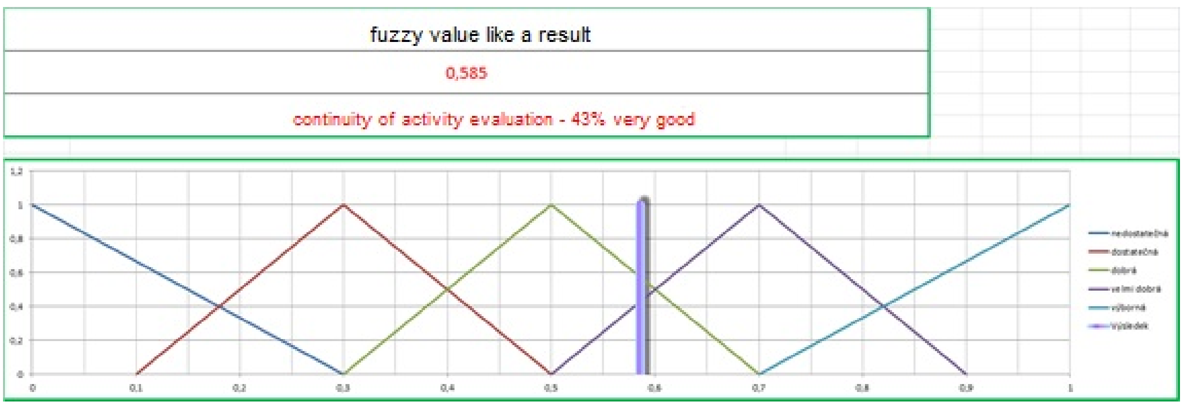

Fig. 3.
Calculation Tool – Final Evaluation
Source: Author

If the calculation determines that the activity does not affect the continuity of activities, the weight "0" is added on sheet 1, and this does not count towards the total result. Additional sheets of the file are for each activity evaluation. The visual form of the evaluation of individual activities was presented in Figure 1. Other data are not required. The calculation tool determines the value of the individual activity as well as the rated entity (enterprise).

6. Conclusion

The properly configured BCMS of the transport company or infrastructure manager copies the optimal limits that BCMS has to reach. From the assessment of the BCMS activities we will see which ones need to be addressed.
By assessing BCMS, it is possible to optimize the continuity of individual activities and thus reduce the possibility of interruption of traffic and transport services of the area.

LITERATURE REVIEW TOWARD DECENTRALIZED RAILWAY TRAFFIC MANAGEMENT

Elisa Marcelli[1], Paola Pellegrini[2]
[1] *School of Sciences and Technology, University of Camerino, via Madonna delle Carceri 9, Camerino (MC) Italy*
[1,2] *Univ. Lille Nord de France, F-59000 Lille, IFSTTAR, COSYS, LEOST, F-59650 Villeneuve d'Ascq, France*

Abstract: This paper addresses the analysis of the state of the art to tackle problems which may help in designing a decentralized railway traffic management system. The goal is the study of new ways for modelling railway traffic flow, for example, based on the idea of multi-agent systems. In the first part, we discuss the possibility of exploiting the existing research works on driving agents in road traffic management. The analysis of these works makes it clear that road and railway traffic management are not so similar as far as decision making is concerned. Hence, we consider three different approaches. First, we analyse existing consensus problem papers dealing with multi-agent systems. Then, we study the problem of reaching a common decision in decentralized systems using the approach of hierarchical self-organization. Finally, we consider task allocation models. After the overview, a brief analysis about further possible directions is discussed, focusing the attention on some promising models.

Keywords: Railway traffic management, Multi-agent system, Consensus problem, Hierarchical self-organization, Task allocation.

1. Introduction

Traffic management describes the process of coordinating, controlling and organizing traffic to achieve efficiency and effectiveness in the use of existing infrastructure capacity. Currently, railway traffic is managed by dispatchers in a centralized way: a dispatcher has a control area where he operates. The work of the dispatcher can become very demanding, making decisions on the precedence between trains which must cross a junction, which is a location where multiple lines cross, and on the routes of the trains for the minimization of delay propagation in case of perturbation. Indeed, in the timetable, precedence and routes are determined so that trains can travel at the planned speed never encountering congested traffic conditions. However, when an unexpected event perturbs operations, trains travelling at the planned speed may require the use of some parts of infrastructure concurrently, which corresponds to the emergence of conflicts. When this happens, the deployment of a good traffic management solution becomes crucial.
Following current practice, all decision support tools proposing optimization techniques for traffic management consider a centralized decision making (Cacchiani *et al.,* 2014; Corman *et al.,* 2010; Pellegrini *et al.* 2015). Here, decisions are made and imposed to trains so that a system-level utility function is optimized. This utility function is typically related to delay propagation and is then to be minimized.
In this paper we consider a radically different approach for railway traffic management, in which decisions are made in a decentralized way: trains themselves make decisions on how to solve conflicts, choosing precedence and routes.
Specifically, here we propose a literature review on possible ways of modelling such a decentralized system for railway traffic management.
As we will see in the following, and as intuition suggests, an interesting possibility is based on the idea of multi-agent systems (MAS). A MAS (Ferber, 1999) is an aggregation of agents, intelligent autonomous entities with the capability of observing the environment, communicating with each-other and finally making decisions based on these observations and communications. The organization and co-operation factors, together with the capability of quickly changing opinion based on external considerations, make agents a good choice for controlling many different vehicles. Although this modelling is widely used in road traffic management, it represents a very novel idea in the railway system.
Initially, we summarize the very little literature existing on decentralized railway traffic management. Then, we discuss the possibility of using the existing research works on driving agents in road traffic as a basis. The analysis of these works clarifies that the road traffic problems tackled with multi-agent systems in the literature are different and not really compatible with the one we are interested in for railway. Specifically, major differences exist in the need for collaboration and agreement in general. Hence, we focus on the more general literature concerning these needs, mostly in MAS, and in particular on three different decision making approaches. First, we analyse the rich literature on consensus problems. Then, we study the problem of reaching a common decision in decentralized systems in general using the approach of hierarchical self-organization. Finally, we consider the possibility of applying task allocation techniques.
The structure of this paper is organized as follows. In Section 2 we take stock of the situation on decentralized railway management. In Section 3 we provide an overview of existing decentralized road traffic systems. In Section 4 we analyse the problem of consensus in decentralized systems. Respectively in Sections 5 and 6 we describe hierarchical self-organization approaches and task allocation techniques. Finally, in Section 7 we draw conclusions.

2. Decentralized Railway System

In the existing literature, when railway traffic management is said to be tackled in a decentralized way, the system is actually split into subsystems, each one relying on one individual to make decisions and provide directions (Corman *et*

[1] Corresponding author: elisa.marcelli@unicam.it

al., 2014; Corman *et al.,* 2010; Johnson & Nguyen*,* 2016). Therefore, traffic in a railway infrastructure is not really managed in a decentralized way but is simply partitioned into geographically smaller areas where a centralized management is in place.
To the best of our knowledge, the only two papers dealing with an actual decentralized system are (Yong *et al.,* 2017) and (Fay, 2010). In (Yong *et al.,* 2017), decentralized railway management is achieved through swarm intelligence: trains that are locally moving in the same direction and facing a possible common conflict situation are grouped into a swarm. To coordinate with its neighbours in the swarm, each train uses a train-to-train communication system. To occupy a resource, trains have to send the request to a decentralized dispatching algorithm which verifies the feasibility of such request. If the requested resource is free the algorithm allows the train to occupy it, otherwise the request is put in a pending list.
Although this paper presents an innovative idea, it represents a theoretical starting point that does not give tangible solutions. For example, no investigation is made on the mechanism to define and adapt swarm compositions in complex networks and throughout time. Moreover the dispatching algorithm, which in our eyes constitutes the most important part of the approach, is only sketched.
An approach using autonomous agents is proposed in (Fay, 2010). The paper describes how agents could be used for both planning long term schedules and making short term changes when needed. A peculiarity of this work is that agents represent trains and tracks: when a journey has to be planned, the considered train (T-agent) creates a list of all possible routes it may take, ordered in terms of its own priority criteria, and starts negotiating with tracks (S-agents) the cost of using them. If the cost is too high for all the possible routes, the journey is cancelled. In this system, the interest of the T-agent is finding the more suitable route at a convenient price; at the same time, S-agents aim to fix costs so as to satisfy as many trains as possible to maximize revenues. Hence, both T-agents and S-agents have an active role in the negotiations. As (Yong *et al.,* 2017), this paper proposes an innovative idea but does not deepen it, remaining a hypothetical notion. Specifically, no explanation is attempted to define track costs, for example in case of competition. Moreover, only one to one negotiation is envisaged, neglecting traffic conditions even in real time. In any case, no proper algorithm for the negotiation is discussed. Hence, no actual solution for decentralized traffic management has been proposed yet.
In the next session we consider a different means of transport for which a substantial amount of literature exists: we propose a review of some decentralized road traffic methods that have been proposed.

3. Road Traffic System

Approaches for decentralized traffic management have been widely studied in the field of road transportation. The number of vehicles moving on road or public highway has significantly grown in the last years and traffic congestion has become a major issue in many metropolis and crowded areas. To analyse this issue, many works regarding the idea of constructing simulation models for road traffic management have been presented (Burmeister *et al.,* 1997; Ehlert Patrick & Rothkrantz Leon*,* 2001; Li *et al.,* 2003). These models describe the use of MAS to deal with vehicles and infrastructures, with the goal of testing principles and making useful traffic control plans of action.
In (Burmeister *et al.,* 1997) agents are used to simulate traffic situations. Driver/vehicle agents are modelled having beliefs, desires and intentions as internal states (Haddadi & Sundermeyer*,* 1996). Each agent can communicate with the others. Based on this communication, together with the information it receives from external sensors and its own motivation, it makes decisions.
In (Ehlert Patrick & Rothkrantz Leon*,* 2001) it is described the use of reactive agents in controlling a road vehicle in a simulated traffic environment. Each driving agent receives external information about the environment through sensors and, based on these, makes its own decisions. The behaviour that an agent applies is given by a set of rules which describes actions that each vehicle should follow in order to keep a civil conduct, e.g., always driving on the streets or decelerating when a crossroad is met. These rules are influenced by several behaviour parameters with the aim of creating different driving styles, as happens in real life. In this way, it is possible to let some vehicles drive more or less aggressively, or regulate their speed as preferred, making every agent in some way dissimilar from each other.
Also in (Li *et al.,* 2003) MAS are used to design a microscopic traffic simulator. Each vehicle is described independently leaving the possibility of local interactions.
Apart from simulations, some works focus on the use of agents in the implementation of policies and guidelines on road traffic control. In (Dresner & Stone*,* 2004), agents are used to study systems to primarily reduce traffic jams in crossroads. As before, the system is decentralized and each agent can autonomously make its own decisions submitting to road rules. The paper proposes a reservation-based procedure to be used instead of traffic lights, so that vehicles have time gaps during which they are allowed to cross the crossroad.
A policy for collision control between multiple vehicles is given in (Pallottino *et al.,* 2007). The article uses MAS to study the cooperation between several vehicles on the same route, with the possibility of leaving or entering the scene at any time, focusing on collision avoidance.
MAS are also used to study cooperative control in road traffic management, namely the coordination of a group of vehicles that travel on the same route. For example, the collaboration between autonomous vehicles is the central topic of (Fax & Murray, 2004). The main goal of the paper is to get a control approach of the formation of groups of agents, robust to communication network changes.

A possible solution to the problem of railway decentralization would be to take the research work made on driving agents in road traffic management and use it as a starting point. However, even if they may look like similar problems, road and railway traffic management have some features that make them dissimilar in some important aspects. Indeed, common road traffic vehicles have some rules to follow, such as stop at red traffic lights, slow down at yellow ones or keep a safety distance with others. However, in general they tend to have a selfish behaviour, not caring about each other. This attitude is called human error in (Djelassi *et al.,* 2006), where failures are analysed in order to understand and predict car driving violations.

In this regard, some works focus on the importance of driver violations in the case of road traffic simulation. For example, in (Doniec *et al.,* 2008) agents are used to describe a simulation, taking as a model real drivers dynamic behaviours. The aim of the article is to make the simulation as realistic as possible, focusing on some features that are an important part of real driver decision making processes. In particular, the model relies on opportunistic strategies.

In railway traffic, this kind of behaviour cannot be accepted. It is enough to think of a junction where conflicts among several trains occur: it is of primary importance that trains come to a common decision on who passes first and strictly follow it.

Although not in traffic system, this problem of coming to a common decision is object of a rich branch of literature. It is often modelled as the problem of reaching *consensus* and is a fundamental matter in distributed environments such as MAS. In the next section we propose a review of this literature.

4. Consensus Problem

The decision making process in decentralized systems is often modelled as the *consensus* problem. Here, consensus means getting all the components to reach a common decision about certain tasks of interest.

In MAS, reaching consensus consists in a procedure where all the agents in the network interact with each other, with the purpose of reaching an agreement on a common behaviour. The process that leads to consensus is modelled through iterative interaction algorithms where, at each iteration, agents reveal their opinion to the others, moving toward a common behaviour.

In principle, in railway traffic management, reaching a consensus may be seen as the process of getting a common decision that all the components of the system need to observe and follow.

Over the last decades the increasingly frequent use of distributed systems has made the design of converging consensus algorithms a central research topic. Overviews focusing on recent works on consensus and MAS are given in the surveys (Cao *et al.,* 2013) and (Olfati-Saber *et al.,* 2007). Both studies analyse consensus in complex dynamic systems, taking into account the effects of time delay in the general performance.

The problem of consensus under time delays is also studied in (Tian & Liu*,* 2008). Two different types of time delay are considered: input delay and communication delay. The first defines the delay given by the necessary time for the input to arrive at the agents, the latter is given by the time gap between transmitting information and receiving it. The paper analyses the consensus problem with input delay only and when both information and input delay are present.

A particular kind of consensus problem in MAS is the one that considers one agent as special, with dynamics independent of the others, and is known as *leader-following* consensus problem. For example, (Ni & Cheng*,* 2010) considers the leader following consensus problem in the case of time-varying interaction topology, i.e., when the structure of the interconnection between agents is not fixed but changes over time.

Similarly, (Ren & Beard, 2005) considers topologies that change in a dynamic way. It examines the conditions that guarantee the convergence in time-varying networks when the information exchange is not complete and trusted.

Anyway, an important feature that generally characterizes consensus algorithms in MAS is that, in order to reach an agreement, all the agents have to choose the same solution between a set of feasible ones. To do so, every consensus algorithm performs a number of iterations before converging. For example, it may be necessary to reach a consensus on the speed of several agents sharing an infrastructure. Initially all agents travel at different speeds. Throughout iterations, they progressively start moving uniformly, converging to a somehow average speed, or to the speed of the leader. In railway traffic management, we aim to solve problems of different nature: for example, which train goes first if several ones must cross a common point. Such problems cannot be effectively dealt with through iterative adjustments. Hence, the algorithms proposed to tackle the consensus problem are not suitable.

In the next section, we consider a different decision making approach based on hierarchies.

5. Hierarchy

A *hierarchy* is the organization of components or individuals into groups, based on their degree of importance. The development of hierarchical systems is very common in social structures of any kind. In these systems, the higher the importance of a member is, the more it has privileges and power.

Dominance hierarchy formations are a common peculiarity of animal kingdoms, where animals behave based on their hierarchical ranking. The accepted explanation for the presence of animal hierarchies is the so called winner-loser effect. With winner-loser effect it is defined the condition in which the individual possibility of winning or losing a contest is affected by previous results. Namely, if an individual wins a contest, this raises its probability of winning the following one; respectively, with the losing effect, losing a contest decreases the probability of winning in the future.

Developing a hierarchical structure in the problem of decentralized traffic management may be considered as defining a hierarchy of trains. As we will see, this hierarchy may be caused by many factors and defines the order of passage of trains in a junction.

Winner-loser effects have been widely discussed in animal groups. In (Dugatkin, 1997) a model for the formation of hierarchies is proposed. In the paper, each individual is characterized by two factors: the winner-loser effect and the resource holding power (RHP). The first one, as already explained, is strictly related to the results of the previous contests; instead the RHP is a physical attribute that defines the capability of an individual of winning or losing (e.g., its strength). An important feature of the proposed model is that, when a contest occurs, each individual has no information about its opponent, except for a time invariant assessment of its RHP. The model is used to examine how winner-loser effects affect the formation of hierarchical structures. It considers different cases: when only one between the winner and the loser effect is significant and if both winner-loser effects matter.

The fact of having no information on the opponents is no longer present in (Dugatkin & Dugatkin, 2007), where the same research group presents an updated version of the model. In the paper, each individual has an estimate of its opponent's RHP. The accuracy of the estimation changes and its effects on the formation of hierarchies are studied.

The two models just mentioned are the central topic of (Kura *et al.,* 2015). The paper evaluates and analyses the results of these models on the basis of simulations, mainly focusing on the number of contests necessary for the emergence of hierarchical structures.

A review of previously published works is also proposed in (Lindquist & Chase, 2009). It analyses (Dugatkin, 1997) together with the models in (Bonabeau *et al.,* 1999) and (Hemelrijk, 2000) both examining the emergence of hierarchies due to winner-loser effects. Apart from examining the accuracy of these models to represent the observed behaviour of groups of individuals, an interesting aim of the review is to try finding alternative ways of defining the RHP. As already said before, the RHP is an inner value that specifies the strength of each individual and, therefore, the models do not give a mathematical formulation to quantify it. The paper links the RHP of an individual to the number of times it won and lost, making it easily calculable.

The idea proposed by these models could fit well for our goal of modelling decentralized decision making in railway traffic management. Both winner-loser effect and RHP value are adaptable concepts in the case of railway traffic management. In our case, a contest takes place when more than a train wishes to cross a junction at the same time. It is trivial to see that if only two trains are meeting, winning a contest is equivalent to going first. Instead, if several trains meet, it is less immediate to understand who wins and who loses. A way of dealing with more trains could be to establish a ranking list of the trains having to cross a junction and assign a value to each train based on its position on this list.

The winner-loser effect can be seen as based on the history of each train, defined by what happened in the previous meetings. The RHP value could represent the different types of trains that may have different priority, e.g., high-speed trains, conventional trains, freight trains and dangerous freight trains.

Note that, using this kind of model makes the background information and the type of each train affect its path, but does not consider any other factor which may have an impact on the importance for a train to go first.

Somehow allowing the consideration of other factors, a different approach is proposed in (Broom & Cannings, 2002), where hierarchy formations are established using game theory. In particular, this work uses a multi-player version of the Hawk-Dove game. In this game, when two players aim to the control of a resource, they can chose between an aggressive hawk strategy or a passive dove one. The choice of the strategy depends on the expected reward obtainable with it. When two haws fight, they go on until one decides to leave because of the injuries sustained; if two doves meet, they don't fight but equally share the resource; when a dove and a hawk meet, the dove leaves and the hawk gets the entire resource. Hence, this model has the peculiarity of not having past results interfering with the possibility of winning or losing a contest: no winning-losing effect is present but, based on the strategy chosen, an individual has a defined probability of winning. An earlier and more elaborated version was proposed by the same research group in (Broom *et al.,* 1997), where more than two individuals can compete at the same time. Although this version may be suitable to represent many situations, it comes with a significant increase of complexity. This complexity is not always acceptable, especially in dynamic environments.

The idea of using strategies as proposed in (Broom & Cannings, 2002) and (Broom *et al.,* 1997) could be interesting for the problem we are considering. To apply it, it would be necessary to define what the reward associated to a strategy is in the trivial case of several trains meeting at a junction: these rewards may be linked to the features of the trains but also to external factors such as the delay, or the number of passengers or the importance of the goods transported. As a further step, this model could be extended to a more complex system, with the consequence of having to deal with multiple agents and a large set of all possible strategies, for example based on the need to cross several junctions one after the other. Moreover, the possibilities of having or not perfect information on other agents' rewards would be an interesting development, particularly suitable for the railway traffic context in which we may think of different railway undertakings not wanting to share their utility functions. As mentioned above, unlike the winner-loser approaches, this model can value how important is for a train to go first. In this way, the model allows to better deal with peculiar situations, for example when two trains meet right after the departure, and hence without any background on previous contests.

The last section considers a different approach based on the idea of task allocation, which is not related to hierarchies but could represent a valid alternative.

6. Task Allocation

The problem of assigning tasks among a collection of agents is known as *task allocation* and is a very common problem in everyday life applications. A remarkable example is easily recognizable in all the most famous electronic commerce companies, such as Amazon or eBay, funded in the last couple of decades. In fact, when an order arrives, it is assigned to an agent, usually a robot, that takes care of the preparation tasks. These companies usually have to deal with a huge number of shipments per day, making the process of organizing the distribution of tasks among different agents essential.

In railway traffic management, assigning tasks to a set of trains needing to cross a junction may mean deciding the order of the trains: the tasks may be going first, second and so on.

The definition of a taxonomy of task allocation problems is the central topic of (Gerkey & Matarić, 2004) and (Nunes *et al.*, 2017). In (Gerkey & Matarić, 2004) multi-robot task allocation problems are classified using three features: robot, task and time. Different approaches are proposed if: robots can manage only one task at a time or are capable of handling more tasks; tasks require one or more robots; allocation time must be immediate or can be planned in advance. Similarly, (Nunes *et al.*, 2017) classifies task allocation problems but focusing on temporal and ordering constrains. Hence, tasks are classified based on their urgency of being carried out and on the specific order they need to be executed in. In (Gerkey & Matarić, 2004) all the approaches considered are performed in a centralized way, while (Nunes *et al.*, 2017) gives a brief categorization of decentralized approaches underlying, however, the limited number of existing works.

In (Fatima & Wooldridge, 2001) the problem of task allocation is analysed in the context of MAS, proposing a model called TRACE (Task and Resource Allocation in Computational Economy). The paper characterizes each task by four factors: type, duration, deadline and priority. The type factor specifies the necessary characteristics that an agent should have in order to accomplish the task; the amount of time needed to complete the task is the duration; the deadline gives information about the latest possible time for a task to be carried out; the priority tells how important the task is. Each agent, to whom a task can be allocated, can be different and have dissimilar abilities from the others. The TRACE model groups agents in so-called organizations. In each of them there is an agent in charge or resource management and a set of agents who may be either permanent or marketable. A task can be allocated either to an agent or to an organization. When it is allocated to an agent, the resource manager can ask for help to the other agents in the organization. When it is assigned to an organization, the resource manager decides if it can be accomplished with the available resources. Otherwise, he can ask for extra help to the other organizations who may accept to temporarily share their marketable agents. This model is not suitable for the case of railway traffic management because of the too specific characteristics that define each task (i.e., type, duration, deadline and priority). In the specific case of railway, tasks characteristics strictly depend on the agents (i.e., trains) they are allocated to. For example, if the task "going first through a junction" is allocated to a high-speed train running at full speed, it will have a very short duration. If it is allocated to a freight train right after a stop, the duration will be much longer.

A mathematical approach to the task allocation problem is presented in (Fanti *et al.,* 2016). The paper studies the problem of allocating tasks to a set of agents represented as nodes in a graph: two nodes are linked if the corresponding agents can communicate with each other. The authors propose a distributed iterative algorithm to perform a task allocation through a linear programming model. At each iteration a subset of tasks are allocated to agents in neighbourhood of a randomly selected one. If throughout successive iterations all tasks can be allocated, the algorithm stops. Otherwise some constrains in the local allocations are relaxed.

In (Gao & Luo, 2008) the task allocation problem is studied in the field of a multi-robot system using an Artificial Immune Network model. In the system, B cells produce antibodies that interact with antigens, with the feature that each antibody can interact only with one specific type of antigen. In the paper, robots behave as B cells and tasks as antigens. When a task has to be allocated, each robot is associated to a specific value that describes its capability to perform the task. The proposed algorithm chooses the robot for a specific task based on this value.

The last two models proposed could both represent interesting solutions for modelling decentralized railway traffic management. In particular, the global solution presented in (Gao & Luo, 2008), can be almost directly used in our case. The cells allocated to each antigen may be the trains which have to cross a specific junction. The value describing the capability to perform a task may reflect aspects as trains priorities, current state and possibly the cost of the delay which may come from the task allocation.

Instead, for applying (Fanti *et al.,* 2016) to our problem, the model proposed should be adapted. However, it is particularly interesting due to the use of the concept of neighbourhood. In our case, the neighbourhood may be interpreted in temporal terms: the task allocation may be done only considering the trains which get at a junction in a certain time interval. As time passes, the interval may shift and, hence, the neighbourhood may change.

7. Conclusions

In this paper we proposed an analysis of the state of the art aiming to identify possible ways to model decentralized railway traffic management. After describing the current literature on decentralized railway systems, we focused on the wide existing one on decentralized road traffic systems. Although intuitively the two systems may appear quite similar, we realized that important differences exist and this convinced us to head toward other directions. In particular, we analysed the process of making decisions in decentralized systems, specifically the consensus problem in MAS. Then,

we considered two different decision making approaches, respectively using hierarchical models and task allocation, finding promising ideas that could be actually used for modelling decentralized railway traffic management.
In the future we wish to extend the work with the study of game theory models, which we believe may represent an interesting development and we only very quickly considered in this paper.

Acknowledgements

The work of Elisa Marcelli was supported by University of Camerino, Italy, with a six-month scholarship for recent M.Sc. graduated for further study or training outside Italy. The authors would like to thank Professor Renato De Leone who made the collaboration between University of Camerino and IFSTTAR possible.

SETTING UP COMMUNITIES OF INTEREST FOR THE ITS INDUSTRY

Komninos N.[1], Passas Isidoros A.[2], Martinidis George[3], Schoina Maria[4]
[1,2] URENIO Research Aristotle University of Thessaloniki, Greece
[3,4] Intelspace SA, Greece

Abstract: The concept of Communities of Interest (CoI) is used in a variety of landscapes to describe an agglomeration of entities that can be of any type of organizations or people that are concerned with the exchange of information in some subject area or that share a common goal or environment. In the landscape of Intelligent Transport Systems (ITS), important actors include enterprises, academia, policy makers, associations, consultancies, and, of course, the public as end users. The paper presents an approach for setting up CoI in the ITS field. These can be structured around specific cases, which can act as examples of good practice and bases for gathering relevant stakeholders. In this paper, four cases of CoI, focused on particular sub-fields or activities such as traffic management, water-based transport of goods and railway safety, are examined. The creation of these Communities, according to the proposed approach, should follow a structured process with clearly defined incentives and processes for ensuring their goals. The proposed approach advocates the functioning of CoI in two or three different tiers, from an "internal" one that includes only the CoI organizers and administrators to an "external" one that is open to the general public. Certain paradigms of this approach based on "NEWBITS", EC-H2020 funded project, are provided in the paper. As a critical component for the efficient functioning of the CoIs a web-based platform is proposed, on which the interactions between the members of a CoI and their engagement to new initiatives and projects can be organized, motivated, supported and monitored. The key role of CoI is to support a more intensive and productive interaction between ITS stakeholders, which in turn can facilitate and accelerate the application of ITS solutions in practice and advance the field forward.

Keywords: communities of interest; intelligent transport systems; processes; online platform; innovation; smart solutions.

1. Introduction

The concept of Communities of Interests (CoI) has been used in a variety of different environments and settings (Aiello et al., 2005; McDaniel et al., 2006). One of the identified definitions of a Community of Interest (CoI) is an agglomeration of people -or actors in general, such as organizations- that are concerned with the exchange of information in some subject area (Renner, 2001, p.4) or that share a common goal or environment (Aiello et al., 2005).
Using the above definition, it seems that the CoI is a broad concept that can be used for any group of actors, organizations or stakeholders operating within a given field and/or environment that exchange information and strive towards a common goal. CoI however, should not be confused with other structures, such as networks. Communities and networks can be viewed as two different aspects of social structuring which, as a result, require different forms of developmental work. In a "network", which is viewed as a set of nodes and links, identifying information flows and helpful linkages, the emphasis lies on the personal interactions and connections among participants. On the other hand, the concept of "community" places greater emphasis on the development of a shared identity around a topic that represents a collective intention (Wenger, Trayner & de Laat, 2011).
In practice, communities and networks are often difficult to differentiate. Very few groups have one of the above aspects so clearly pronounced that can be easily identified as "pure" communities or "pure" networks. For most groups, the two aspects are combined in various ways. A community usually involves a network of relationships, while many networks exist because participants are all committed to some kind of joint goal or venture (Wenger, Trayner & de Laat, 2011). Communities and networks produce social capital, the networks and connections among people, which complements "traditional" resources such as physical and human capital, in order to produce better outcomes for innovation and growth (Akcomak & Ter Weel, 2009). Communities also allow the exploration and support of interaction between actors, which enhances collaborative practice (Davis & Mason-Jones, 2017).
It follows that in the field of ITS, CoI can consist of stakeholders that are working -or at least communicating- with each other while striving towards the common goal of developing and establishing an intelligent transport system or promoting an innovative service / solution into market (Angelidou et al., 2015). Therefore, joining together an assortment of ITS actors and stakeholders into a CoI, that makes them operate one with other, can be an important step towards enhancing ITS and moving from ITS to Collaborative ITS, and the benefits that they entail (Piorkowski, 2010).

2. The Profile of the ITS Industry

2.1. General Information on ITS, Market Value, etc.

The ITS domain covers all modes of transport and considers all elements, i.e. the vehicles, the infrastructure, the drivers and users, all interacting together dynamically (ITS Handbook, 2011). More specifically, ITS cover travel information services, transport management systems, a broad range of mobility services (e.g. smart travel cards, integrated ticketing services), vehicle control and safety systems (e.g. anti-collision warning and control systems) and transportation pricing systems (e.g. electronic toll collection, variable parking fees) (Optimism Project, 2011).

[2] Corresponding author: iapassas@urenio.org

Cooperative ITS (C-ITS) is a subcategory of ITS that has been defined by the European Committee for Standardization (CEN) and European Telecommunications Standards Institute (ETSI) as: “A subset of the overall ITS that communicates and shares information between ITS stations to give advice or facilitate actions with the objective of improving safety, sustainability, efficiency and comfort beyond the scope of stand-alone systems” (NEWBITS Deliverable 2.1 Overview of ITS initiatives in the EU and US).

In other words, C-ITS comprises communication between vehicles (V2V), between vehicles and infrastructure (V2I), infrastructure to vehicle (I2V) and/or between vehicles and other transport participants (V2X), such as pedestrians and cyclists.

Regarding the market areas, in two recent studies (ITS Market Analysis, 2016; ITS Market Insight, 2016), ITS market is segmented by a) component, b) type, and c) application. The component segment relates to market characterisation by technology, comprising surveillance camera, interface board, monitoring & detecting system, telecommunication network, software and others.

The second classification segments the market into five (5) types: Advanced Traveler Information System (ATIS); Advanced Traffic Management System (ATMS); Advanced Transportation Pricing System (ATPS); Advanced Public Transportation System (APTS); and Cooperative Vehicle System (CVS).

The third ITS segment is divided into eight application categories, namely: Traffic management; Road safety and security; Freight management; Public transport; Environment protection; Automotive telematics; Parking management and Road user charging.

According to a report by Global Industry Analysis of April 2014, the global ITS market will reach $26.3 billion by 2010, driven by continued rise in vehicular traffic and the need to regulate traffic flow, enhance road safety, and escalate awareness of the socioenvironmental implications of traffic congestion. From a geographical point of view, it is estimated that Asia-Pacific is foreseen to dominate the ITS market in the forecast period of 2016 – 2022 (Market.biz).

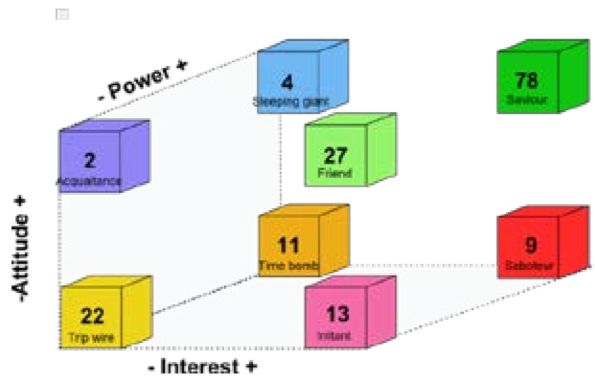

Fig. 1.
Categorisation of stakeholder by interest, power and attitude.
Source: NEWBITS Project (2018), D6.1 CoI Configuration Synthesis Report

2.2. Important Actors

The NEWBITS Project mapped ITS stakeholders, which was not necessarily based on stratified sampling, as the primary factor was ease of accessibility, but it still yields interesting results concerning some features of the ITS industry. The mapping identified 166 stakeholders from 150 unique organisations, which in turn are professionally associated with 4,006 global entities.

The first component included stakeholders interest-power-attitude mapping which, has been performed according to the methodology proposed by Murray-Webster and Simon (2006). This creates a three-dimensional grid based on three characteristics which are important to know when initially considering stakeholders: Power (potential or actual influence), Interest (in the project or program) and Attitude (to the project or program). The grid produces eight different labels based on the position of stakeholders along the dimensions.

The relatively high number of stakeholders (78 or 52% of the total) that have high power, attitude and interest for the project can be considered extremely positive and very hopeful for the functioning of the CoI, as is the fact that a very low number (9 or 6% of the total) have high power and interest combined with low attitude and can be listed as saboteurs.

In short, the vast majority of the mapped stakeholder (90%) were based in the EU, and mainly in Spain, Greece, the UK and the Netherlands. Roughly one third of the stakeholders came from the field of academia, another from the field of industry, while the rest were mostly ITS associations and policy makers. Nearly half of the stakeholders specialised in all or potentially all ITS market segments, while out of those who specialised in a particular segment, advanced traffic management systems (ATMS) was the most common one. Finally, regarding stakeholders’ target market, 42% mainly targets the public market, 31% the private market and 14% focuses on B2B.

Table 1
Identified top ten important entities through number of connections

Label	Number of connections
ITS America	159
International Road Transport Union (IRU)	135
Connekt / ITS Netherlands	126
ISINNOVA	112
Dpt of Mechanical Engineering, Univ. of Western Macedonia	102
Shenzhen Huaru Technology Co., Ltd.	101
ITS Taiwan	88
ITS Finland	82
ITS Spain	78
TREDIT S.A.	70

Source: NEWBITS Project (2018), D6.1 CoI Configuration Synthesis Report

After the creation of the list of the 6,951 connections, a social network analysis tool was used, to identify key components about the network. Social network analysis (SNA) is a powerful way to organize a connected world. Network analysis revealed insights into the ways that the identified entities connect with one another and form groups.
The graph presented in Figure 2 has been constructed using force-directed placement according to Fruchterman- Reingo algorithm. Using the SNA tool, we could focus and analyse specific nodes to understand how each node is connected and its importance to the global ITS landscape.

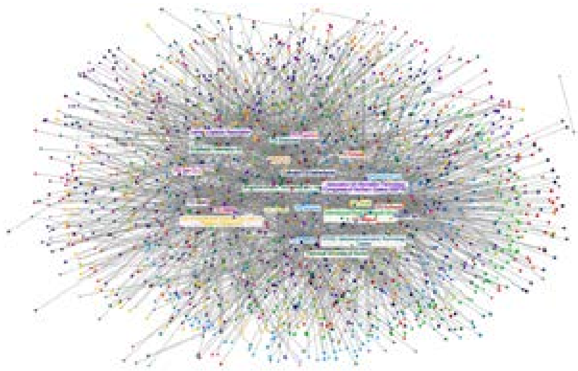

Fig. 2.
Fruchterman- Reingo Network Map

3. A Novel Approach for setting up ITS Communities of Interest

Strategy-consulting businesses rely extensively on consultants' tacit knowledge to solve clients' problems and often invest on building strong knowledge networks or communities of interest to develop people-to-people connections (Venkitachalama & Willmottba, 2017). However, while there are plenty of references in the literature about the form, features and functioning of CoIs (Briard & Carter, 2013; Fischer, 2001) there seem to be no specialized defined frameworks for setting up such CoI. Perhaps it is assumed that setting them up is a straightforward process that needs no special definition, or that they come together naturally in the context of particular projects and initiatives. The experience of several experts involved in the NEWBITS project, however, suggests that the success and active functioning of CoI is not guaranteed.

3.1. The Proposed Novel Approach

The proposed novel approach includes the following four steps presented in Figure 3.

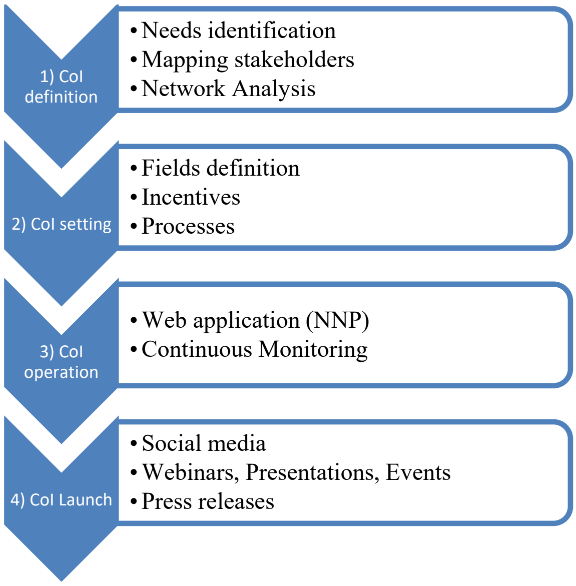

Fig. 3.
A novel approach for setting up CoI
Source: NEWBITS Project (2018), D6.1 CoI Configuration Synthesis Report

To configure the proposed CoI effectively, first it should be justified why potential members would participate in the CoI. The reasoning of such an action is considered a quite complicate multi variable process. The participation in any Community of Interest has both tangible and intangible benefits. CoI are considered as one form of socialization for serving specific scopes. There are different forms of associations or groups of interests that attempt to fulfil similar scopes as the proposed four, NEWBITS, CoI.

The members of CoI can get insight from leading actors such as industry associations and other stakeholders on issues related to the (C) - ITS field regarding the four case studies. The case studies, target key priority areas applicable to ITS and C-ITS across Europe. Initiatives on ITS and C-ITS in Europe and elsewhere, demonstrating best practices from different points of view and how to implement similar in a variety of circumstances, will be also included. The content created by the project's consortium members during the development of the NEWBITS project will be available for discussion among the CoI members. The interaction with other members featuring companies and associations is one of the key benefits. These interactions are the realization of the networking opportunities between the members of the CoI.

The foreseen benefits for the potential members will be further elaborated, though according to initial feedback from the consortium: i) raising the awareness on the state of the art on the fields of (C-) ICT; and ii) the development of common initiatives (Projects EC funded, national and private) are considered important. Potential match making of suppliers and customers of the C-ITS solutions / services and the potential opportunities to implement crowdfunding campaigns look promising.

The operation of communities requires time and effort from their members, so members need motivation in order to contribute effectively (Abouzahra & Tan, 2014). The issue of potential incentives that can be used to motivate stakeholders and actors into joining the different tiers of membership has been pointed out between the NEWBITS partners. What follows is the result of a brief study on potential incentives that are used in forming CoIs.

Incentives that can be used to motivate actors into joining the CoI can be divided into categories, such as practical, financial, social and emotional. Financial incentives are usually a main driver. However, direct financial incentives obviously require the availability of funding for this purpose, which is not always available. The literature shows that incorporating economic incentives can even be counterproductive (Camerer & Hogarth, 1999), or that economic incentives have a tendency to increase quantity but not quality (Mason & Watts, 2009). When considering financial incentives, it is also possible to open up the focus and include not only tangible but with intangible incentives, such as the access to future benefits or access to funding sources, as it is usually found in start-up accelerators' environments. The consideration of potential incentives should not ignore the sociological and psychological aspects stemming from these approaches, which are vital as means for the self-organisation of such communities and are often missing from peer-to-peer systems (Antoniadis & Le Grand, 2007).

Each of the four CoI includes three tiers. Each tier is defined by its scope, members and visibility to public. Tier 1 is comprised of the project partners and the organisations directly involved with the project, aiming to internally support the NEWBITS work packages. Tier 2 has the role of an advanced group of ITS experts. Tier 3 is essentially open to all and has the role of promoting ITS and ITS-related initiatives and collaborations. The following diagram (Figure 4) presents the structure of the web platform that was created to support the above four CoIs and their three Tiers.

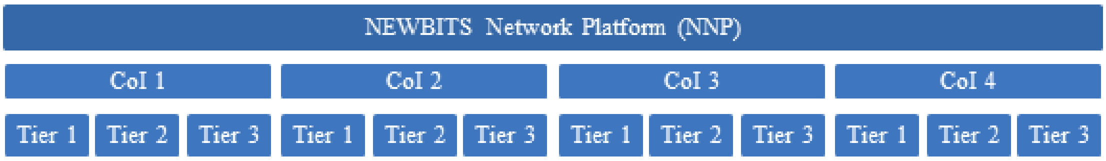

Fig. 4.
NNP to support four Communities of Interest and three tiers per CoI
Source: NEWBITS Project (2018), D6.1 CoI Configuration Synthesis Report

Nowadays, the development of digital platforms and online applications is expanding radically, affecting significantly human activities at all levels, from policy making and governance, to socioeconomic models of production (Kakderi, Psaltoglou and Fellnhofer, 2018). Collaboration platforms, as the proposed NNP, support collective participation in the innovation process, to boost network effects, and enhance the collaboration and creation of bottom-up innovative solutions to complex problems by their members.

3.2. Examples of this From the NEWBITS Project

The NEWBITS project, exploring new business models for ITS, featured the creation of four different CoI, each structured around a particular sub-field of ITS, and each based on one of the project's case studies. Each initial case study, along with the small group of actors directly involved in it, formed the nucleus of each CoI. Other actors and stakeholders that are active in each particular sub-field were subsequently drawn or invited into the CoI. The four communities are presented in more detail below:

CoI 1: Sustainable Intercity Mobility; Intelligent carpooling services for city communities

It regards a CoI built around intelligent carpooling and car-sharing services made possible by advanced C-ITS platforms that provide state of the art capabilities, such as coordinating different route planners and providing real-time routing advice. The scope is to improve traffic flows, reduce emissions and increase urban road transport efficiency. End users also benefit from lower cost. This CoI aims to involve all relevant stakeholders' groups identified in the related case study: city authorities, transport authorities, Academia, ITS service providers, funding bodies, ITS associations, social media, marketing companies and end users (consumers of the ITS service).

CoI 2: Efficient Traffic Management Systems; An energy efficient service for city intersections

This CoI is structured around the installation and use of intelligent traffic management control systems that provide adaptive traffic control strategies, such as the installation of bi-directional communication system between traffic lights and vehicles, which instruct drivers on how to move efficiently in order to expend less time and energy in intersections. The scope is to improve the flow of traffic and reduce delays and carbon emissions. The CoI will involve the following stakeholders' groups: cities, automotive suppliers, Original Equipment Manufacturers, transport operators, end users, ICT service providers.

The main incentive of the CoI is the identification of new business opportunities on collaborative intelligent transport systems.

CoI 3: Synchro-modal solutions for goods transport on water; Using real-time data to decrease idle time and increase efficiency of hinterland transport

This CoI is built around water transport with efficiency-maximizing solutions using synchromodality, which refers to the possibility of choosing the most optimal transport modality at transhipment points. This is achieved by collecting and transmitting real-time data on container transport, from ship tracking, container handling at port, inland ship and truck transport and handling of the containers at the inland terminal and eventually at the warehouse. The scope is to achieve better planning and shorter transport times by better insight into the logistics chain and the resulting decrease of idle time.

The main stakeholders of this CoI are parties in the supply chain of container transport: shippers, terminal operators, warehouse operators, research organisations, ITS and ICT service providers, Governmental and funding agencies, Port Authority.

The core incentive for joining the CoI is the improvement of the collaborative decision-making process across the various stakeholders.

CoI 4: Railway customer satisfaction and safety; Predictive maintenance for cost reduction and safety in railway operation

It concerns a CoI being built around predictive maintenance for railway networks, identifying and reporting potential issues requiring repair before damages and delays appear. The scope is to improve service efficiency and increase passenger safety. The main stakeholders in this CoI are organisations within the Railway Industry: train manufacturers, Railway infrastructure owners, train operators, service delivery organisations, Railway Regulatory bodies, Railway industry organisations, research organisations. The main incentive for this specific CoI is to foster a fully integrated business network modelling approach to railway industry.

The core functions and tools to support the four CoI through the NNP are the following: Set of tools to support NEWBITS implementation; a Content Management System (CMS); a networking space; a showcase of ITS and C-ITS applications and a Crowdsourcing / Crowdfunding function.

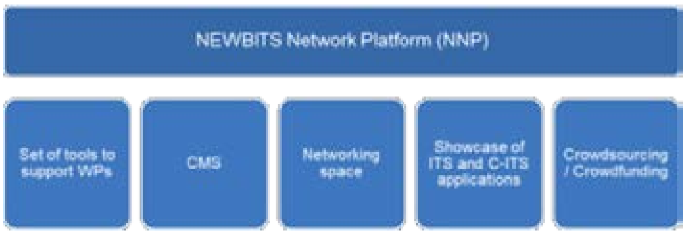

Fig. 5.
NEWBITS Network Platform NNP Core Functions

4. Conclusions

4.1. What the Novel Approach Offers

The proposed methodology is considered novel since it addresses the design and implementation of a CoI in a holistic aspect, taking into consideration from the very beginning the needs of its multi variable stakeholders. As it has been presented, the usual process of implementing a CoI was to identify a specific issue and, following that, to identify its potential members. In the described process, the key members of the CoI have been the ones who are gathered initially, and the CoI has been based upon their know- how and needs in terms of collaboration, in order to address key related issues.
CoI should be supported by online applications in the current networked business ecosystems. One of the success factors of innovative business models is the connection of the companies with each other, as well as with other important actors including the public authorities, to address common challenges in fast, resource-efficient and innovative ways. Online applications, such as the one being developed during the implementation of the NEWBITS project, aim to gather a large number of members, independently of their place of origin, to pursue specific goals and address common issues.

4.2. Further Research

The design and implementation of a CoI is a very challenging and multi-disciplinary issue. It does not only include technical issues for the implementation of the supporting platform but also human capital management issues and social capital ones. To construct CoI and make them successfully operational, initiatives should encourage people to be part of them and motivate them to be "active" as members. There are different theories on how tangible and intangible incentives are working in specific areas, which can be further examined.
In the latest years the emergence of cloud computing paradigm, has increased interest on the adoption of cloud computing from municipalities and city governments towards their effort to address complex urban problems. The analysis of the "STORM CLOUDS" paradigm as a solution for municipalities everywhere in order to (i) deploy a portfolio of smart cities applications related to governance, economy and quality of life on a single cloud-based platform and (ii) use the platform and its accompanied tools to migrate their existing applications to the cloud environment (Kakderi, Komninos and Tsarchopoulos, 2016) can be utilised as a basis to examine the opportunities and threats of migrating the NNP platform, ITS and C-ITS applications to the cloud to support new challenges.
Another issue that can be theoretically examined and justified is how the attitude of CoI members is changing while being part of community as an individual or as part of a company. As part of a company, the CoI member carries norms, values and regulations of the company, while as an individual member, such restrictions do not apply.
Humans are very social. One of the characteristics that we as humans distinguish from other life forms is that we effectively exchange information. Communities of Interest cover both our social aspect and the effective exchange of information, enhancing social capital, which, after all, is the mediating mechanism which transforms innovation to economic growth (Akcomak & Ter Weel, 2009). Communities of Interest cover both our social aspect and the effective exchange of information.

CONCEPTUAL SCHEME OF REGIONAL MODULE FOR INTELLIGENT TRANSPORTATION AND LOGISTICS SYSTEM

Anton Sysoev[1], Dmitry Kadasev[2], Sergey Lyapin[3], Yulia Rizaeva[4], Elena Khabibullina[5]
[1,2,3,4,5] *Lipetsk State Technical University, Lipetsk, Russia*

Abstract: The relevance of creating an intelligent system to manage traffic flow in transportation corridors is an important and actual problem due to the fact of Russia assessing to the World Trade Organization, integration into the global transportation and communication space and the implementation of the federal transit potential, used today only by about 20%. The European Union plans to ensure functioning of TEN-T multimodal European transportation network on the whole its territory. This system will require bringing technical and technological parameters of the Russian transportation system to be included into international transport corridors. The trend of developing the world automobile industry is to create and to implement pilotless vehicles, which will require the creation of appropriate organizational, technical and information infrastructure for their operation. Mechanisms to implement such projects vary from country to country, but the key components are the same. Existing intelligent transportation systems in Russia are semi-structured set of applied programs to solve particular problems arising in traffic flow managing for manned vehicles on certain sections of the transportation network. The development of regional intelligent transportation and logistics modules and their further integration into a single system is a strategic plan, determines the overall competitiveness of Russia in the global market of transportation and logistics services. The problem involves a conceptual approach to using regional transportation network as a module for the global transcontinental network. Such modules should be positioned into this network with minimal investment while ensuring the management of logistics capacities, investments, construction and coordination of transportation and logistics infrastructure compatible with global traffic management systems. In other words, regional modules integrated into a single ITL (which will be integrated into the European and Asian its) will be used to coordinate physical infrastructure and "soft infrastructure" (e.g. coordination of services to be provided in the transportation network). The paper presents a conceptual model to construct a regional module for the intelligent transportation and logistics system.

Keywords: intelligent systems, transportation system, regional module.

1. Introduction

Now Russia faces the problem of creating an international conceptual transportation system to connect existing European and Asian analogical systems. This paper proposes a conceptual project of a regional module for the intelligent traffic management system, controlling motor vehicles along transport corridors, within a single information space. This system has to optimize transportation and logistics processes and to improve the system safety of the transportation process.

The importance of creating an intelligent system for managing the traffic flow within transportation corridors is explained by Russia's accession to the World Trade Organization, the integration into the global transportation and communication space and the implementation of the transit potential of the country, which is used today in approximately 20%.

The European Union plans to ensure the functioning of the TEN-T multimodal trans-European transportation network throughout Europe (by the year 2050 they plan to ensure high quality and capacity of the TEN-T network with an appropriate set of information services). This will require bringing the technical and technological parameters of the Russian transportation complex to the level of the parameters that international transportation corridors require. This will ensure its competitiveness at the level of world analogues. The trend of developing the world automotive industry is to create and to implement unmanned vehicles, which will require the creation of appropriate organizational, technical and information infrastructure for their operation.

In the world practice, intelligent transportation systems (ITS) are recognized as a common transportation ideology to integrate telematics achievements into all types of transportation activities in order to solve economic and social problems such as to reduce accidents, to improve transportation efficiency, to increase general transportation safety, to improve environmental performance. Developing and implementing such systems are a potentially effective competitive innovation business decision and an incentive for the development of a new high–tech industry sector, which is an important anti-crisis factor.

The experiences of the European Union, the United States, Japan, China, Singapore and other countries show that in a market economy, only a single state policy allows to combine the efforts of the state, the subjects of the Federation, business at all levels and sectors of the economy to achieve national goals in the transport sector.

Implementation mechanisms to develop such systems vary from country to country, but key components are the same. Existing ITS in Russia are semistructured sets of applied programs to solve particular problems of managing vehicles within certain sections of the transportation network (e.g., the system to inform drivers about environment conditions, to guide speed limit, etc.).

The development of regional intelligent transportation and logistics modules and their further integration into a single system has a strategic nature and determines the overall competitiveness of Russia in the global market of transportation and logistics services.

[1] Corresponding author: anton_syssoyev@mail.ru

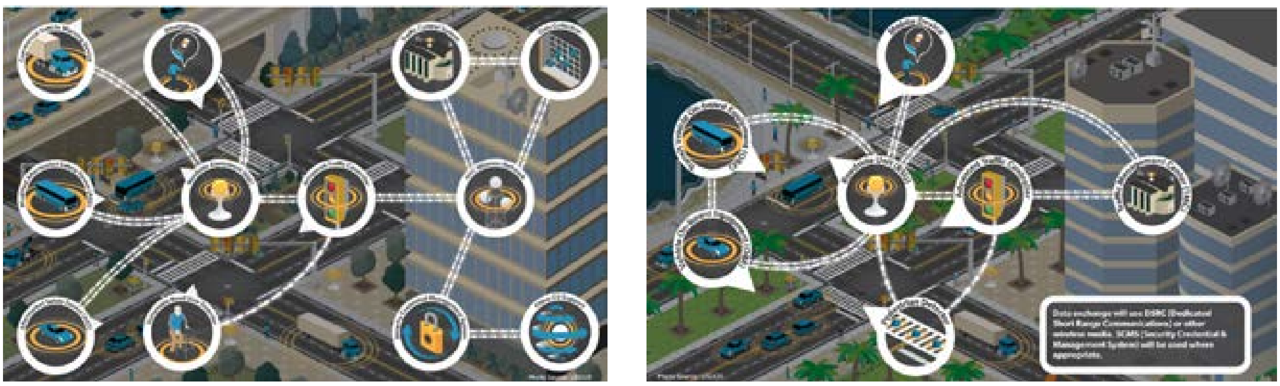
The problem depicted above assumes a conceptual approach to use the transportation regional network as a module of the global transcontinental network, which must be integrated into this network with minimal investment while ensuring the management of logistics capacities, investments, construction and coordination of transportation and logistics infrastructure compatible with global traffic management systems. In other words, regional modules integrated into a single ITLS (which will be integrated into European and Asian ITS) will be used to coordinate physical infrastructure and "soft infrastructure" (e.g. coordination of services to be provided in the transportation network).

2. State of Art in Intelligent Transportation Systems

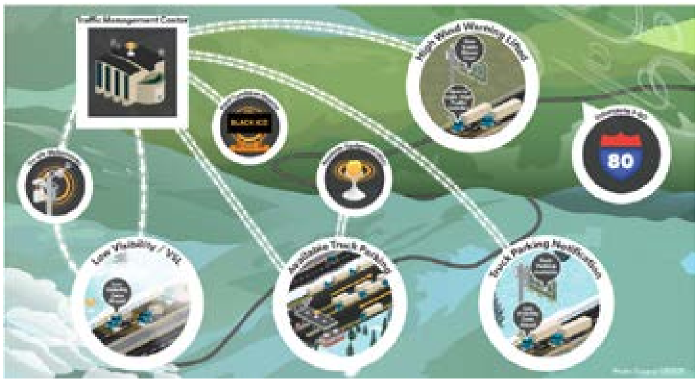
ITS-organizations actively develop and implement projects to forecast traffic volumes and flow-control. These organizations actively work in Japan, America, European Union, Australia, Brazil, China, Canada, Chile, Korea, Malaysia, New Zealand, Singapore, Taiwan, UK. In India, Thailand and some countries of South Africa such scientific schools and organizations are just beginning to develop the concept of smart roads.
Nowadays, the most advanced technologies in the field of ITS are designed in Japan, The USA, Singapore and South Korea. The main directions of developing ITS in these countries are connected vehicle technologies, connected corridors, well-managed and resilient traffic flows, Smart Roads and integration these technologies into Smart City Systems and Internet of Things.

2.1. ITS-America

A single control system of ITS in the United States is "ITS America" (*ITS-America*). The Intelligent Transportation Society of America advances the research and deployment of intelligent transportation technologies to save lives, improve mobility, promote sustainability, and increase efficiency and productivity. The main tasks "ITS America" which it was created to solve are the following: reducing travel time; environmental safety; reduction of accidents and increase transportation system efficiency and productivity. ITS America brings together different organizations from all the relevant sectors: state departments of transportation (DOTs), regional and local transportation and planning agencies, private companies providing ITS products, services and technology, auto manufacturers and suppliers, research organizations, academic institutions and transportation associations.
ITS-America has 3 big projects of ITS-deployment (*Connected Vehicle Pilot Deployment Program*). The first one is NYCDOT Pilot and its applications are the following: Vehicle-to-Vehicle Safety Applications (Forward Crash, Emergency Electronic Brake Lights; Blind Spot Warning; Lane Change Warning; Intersection Movement Assist; Vehicle Turning Right in Front of Bus Warning), Vehicle-to-Infrastructure Safety Applications (Speed Compliance; Curve Speed Compliance; Speed Compliance in Work Zone; Red Light Violation Warning; Oversize Vehicle Compliance; Emergency Communications and Evacuation Information) and Pedestrian Applications (Pedestrian in Signalized Crosswalk; Mobile Accessible Pedestrian Signal System). The second project is THEA Pilot and its applications are the following: Morning traffic backsups (End of Ramp Deceleration Warning, Forward Collision Warning, Emergency Electronic Brake Light Warning), Wrong-Way Drivers (Wrong-Way Entry, Intersection Movement Assist), Pedestrian Safety (Mobile Accessible Pedestrian Signal System, Pedestrian in a Signalized Crosswalk Vehicle Warning), Transit Delays (Transit Signal Priority, Intersection Movement Assist), Streetcar Conflicts (Vehicle Turning Right in Front of Transit Vehicle, Pedestrian in a Signalized Crosswalk Vehicle Warning) and Traffic Progression (Intelligent Signal System, Probe Data Enabled Traffic Monitoring, Intersection Movement Assist). The last of projects is WYDOT Pilot System and its applications are the following: Forward Collision Warning, Infrastructure-to-Vehicle (I2V) Situational Awareness and Work Zone Warning. The conceptual models of these systems are shown in Figure 1.



(a) (b)



(c)

Fig. 1.
The conceptual model of American Intellectual Transportation Systems
(a) NYCDOT Pilot System; (b) THEA Pilot System; (c) WYDOT Pilot System
Source: Connected Vehicle Pilot Fact Sheets (Connected Vehicle Pilot Deployment Program)

ITS-America helps to deploy not only Smart Roads and Smart Cities projects. From the point of view of big corporations and high mobility citizens Integrated Corridor Management (ICM) is the most interesting direction of ITS. ICM (*Connected Corridors Program*) is an entire transportation network—including freeways, arterial streets, transit, parking, travel demand, agency collaboration, and more—and considers all opportunities to move people and goods in the most efficient and safest way possible. The Connected Corridors ICM Architecture is shown in Figure 2.

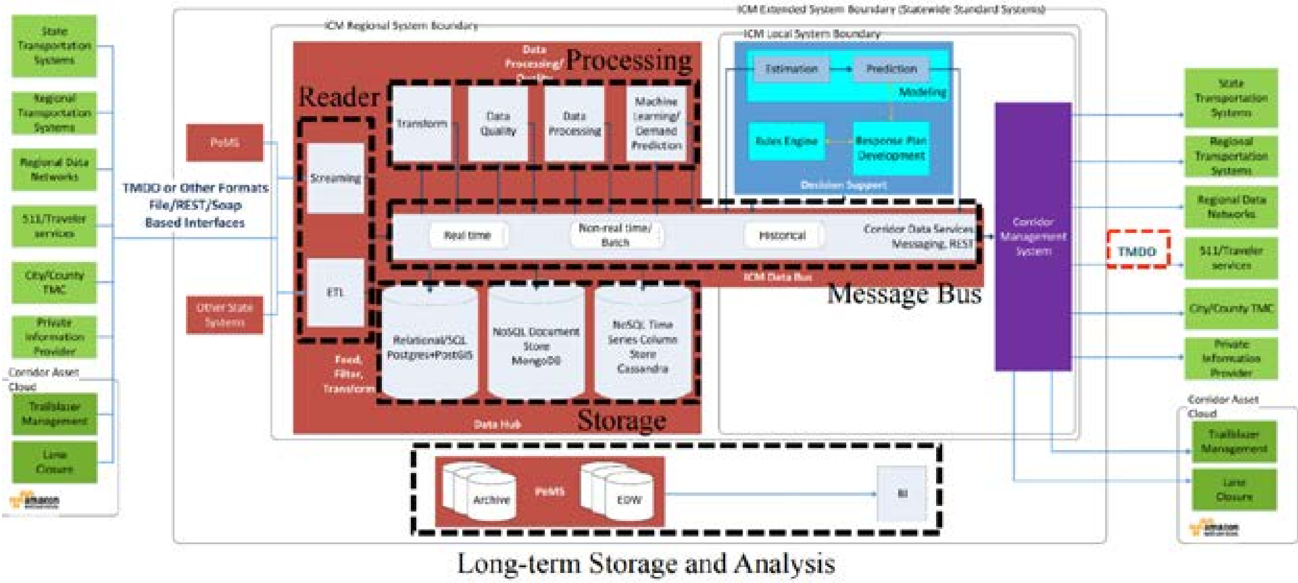


Fig. 2.
Connected Corridors ICM Architecture
Source: (Gan, 2018)

2.2. ITS-Japan

According to ITS Japan concept ITS is a system for solving problems such as safety, efficiency, environment, convenience and recreation (*Hasegawa, 2005*). It was deployed as a set of different application designed to solve a particular problem. So the system architecture (is shown in Figure 3) can be represented as aggregation of user services which have special interfaces to interact among themselves. All user services provide opportunities in the following development fields: sophisticated navigation system, automatic toll collection system, safe driving system, traffic management optimization, road management efficiency, public transport support, commercial vehicle efficiency, support for pedestrians, emergency vehicle operations support.

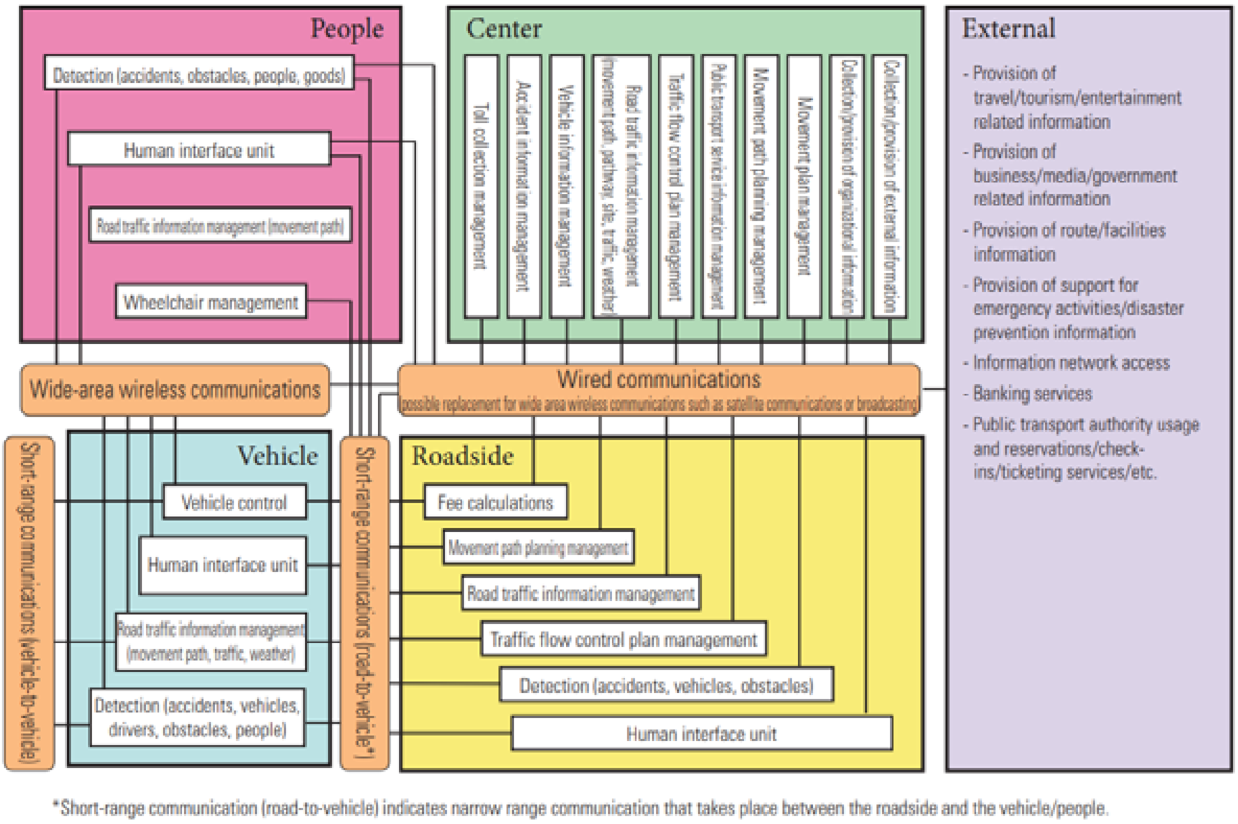

Fig. 3.
Japan ITS Architecture (interconnected subsystems)
Source: (Hasegawa, 2005)

2.3. ITS - Singapore

Singapore officials and researchers deploy ITS as a whole city ecosystem which helps to provide their citizens with a smarter urban mobility. Singapore Land Transport Authority and Intelligent Transportation Society Singapore developed Singapore ITS strategic plan – SMART MOBILITY 2030. According to this paper Singapore's ITS vision is "Moving towards a more connected and interactive land transport community". The central areas of Singapore ITS are Informative, Interactive, Assistive and Green Mobility. The conceptual model of Singapore Intellectual Transportation Systems is shown in Figure 4.

Fig. 4.
Singapore's ITS vision
Source: (Smart Mobility 2030)

2.4. IBM Intelligent Transportation

Not only ITS-organizations of different countries developed their ideas and strategies: nowadays the largest IT-corporation has their own projects connected with ITS. For example, IBM introduced their vision of ITS which meets the needs of the end user while maintaining the benefits of a common architecture. The design of this transportation systems framework conforms to the National ITS Architecture (US). IBM Intelligent Transportation architecture is shown in Figure 5.

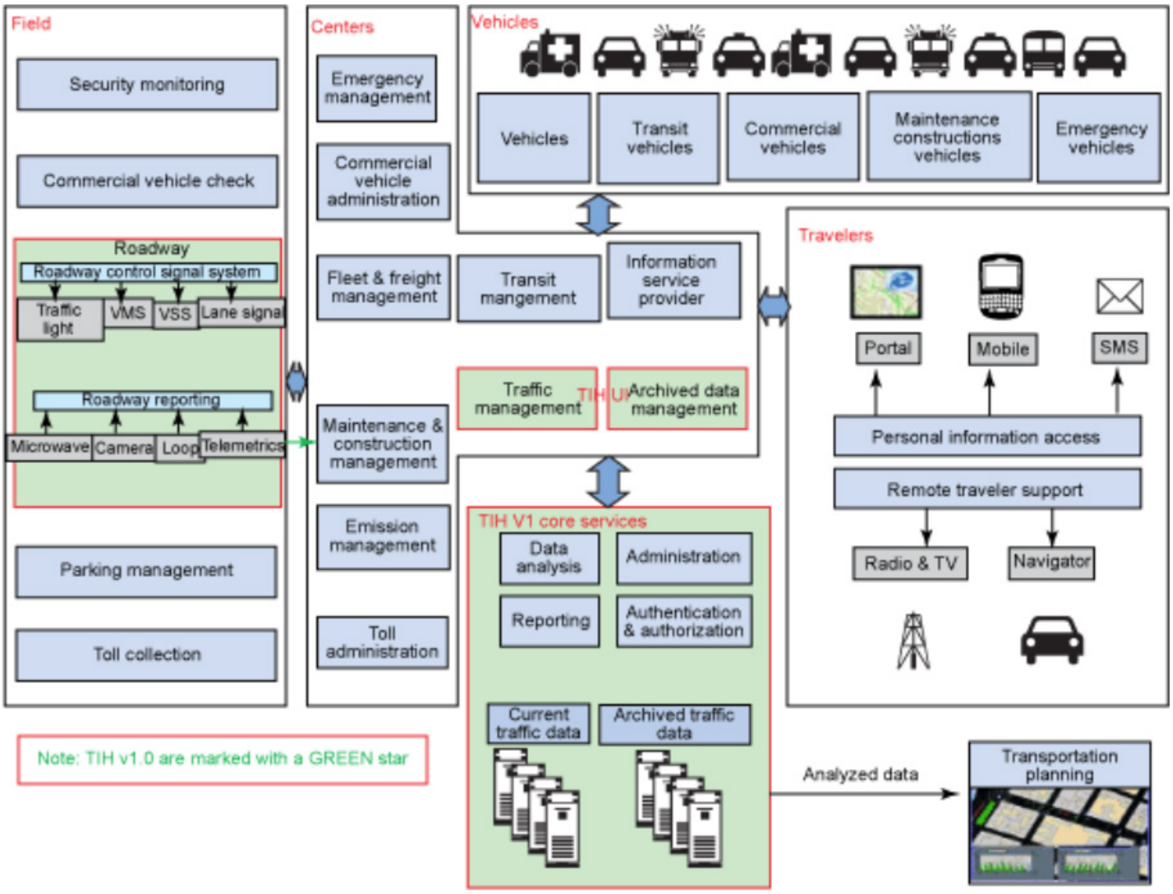

Fig. 5.
IBM Intelligent Transportation high-level architecture
Source: (Laffoon, 2011)

It is clear from these observations that national ITS projects, ideas and strategies has been developed in the same way: to connect all participants of land traffic, collect the data which can be received from their devices and a lot of sensors and automate control and making decisions in transportation systems.

3. Conceptual Scheme of the Regional Module for the Intelligent Transportation and Logistics System

Based on existing researches in Lipetsk State Technical University we propose the following structural scheme to organize the regional module for the intelligent transportation and logistics system of the country. Figure 6 depicts the proposed structure.

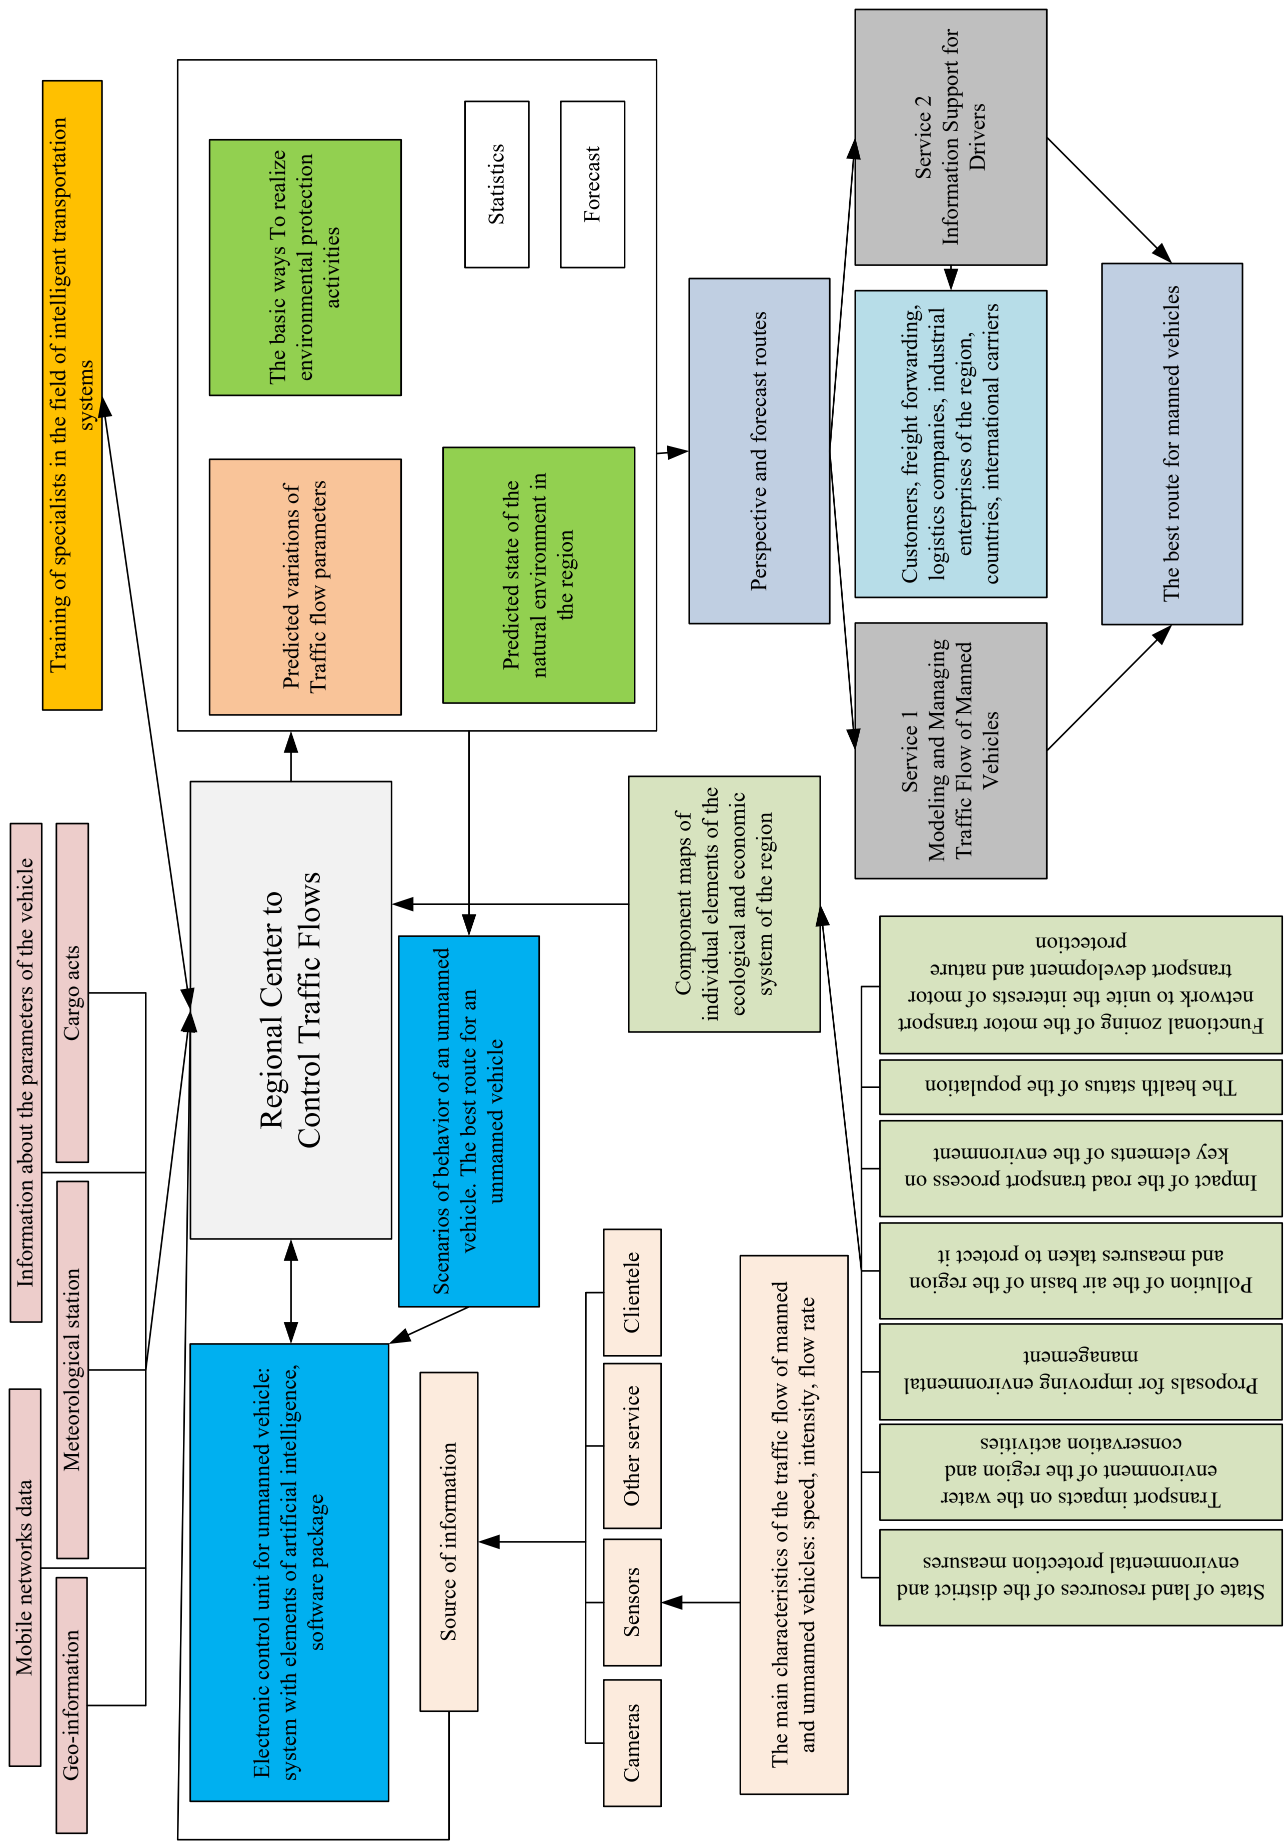

Fig. 6.
Conceptual scheme of the intelligent transportation and logistics system on the regional level

Regional Center to Control Traffic Flows (RCCTF) (*Korchagin, 2011*) consisting of manned and unmanned vehicles delivers following functions: collecting of information about traffic conditions (detailed information about the factors is given on the scheme, cf. Fig. 7) and cargo acts, also processing, analyzing and storing big data; as well as the training of specialists in the field of intelligent transport systems. RCCTF is an academic, scientific-educational center aimed at solving transportation problems using the achievements on intellectual transportation management. Proposed structure should become a platform to implement regional modules of the intelligent transportation and logistics system (ITLS) of the Russian Federation.
Some of the center features are of strategic importance for developing regional transportation system. They are designing system modules of the regional ITLS, forming and developing the strategy of the regional ITLS and the expertize of the proposed features to develop regional ITLS.
To make quick and effective decisions, operators of transport networks used data obtained from information sources in a real-time regime.

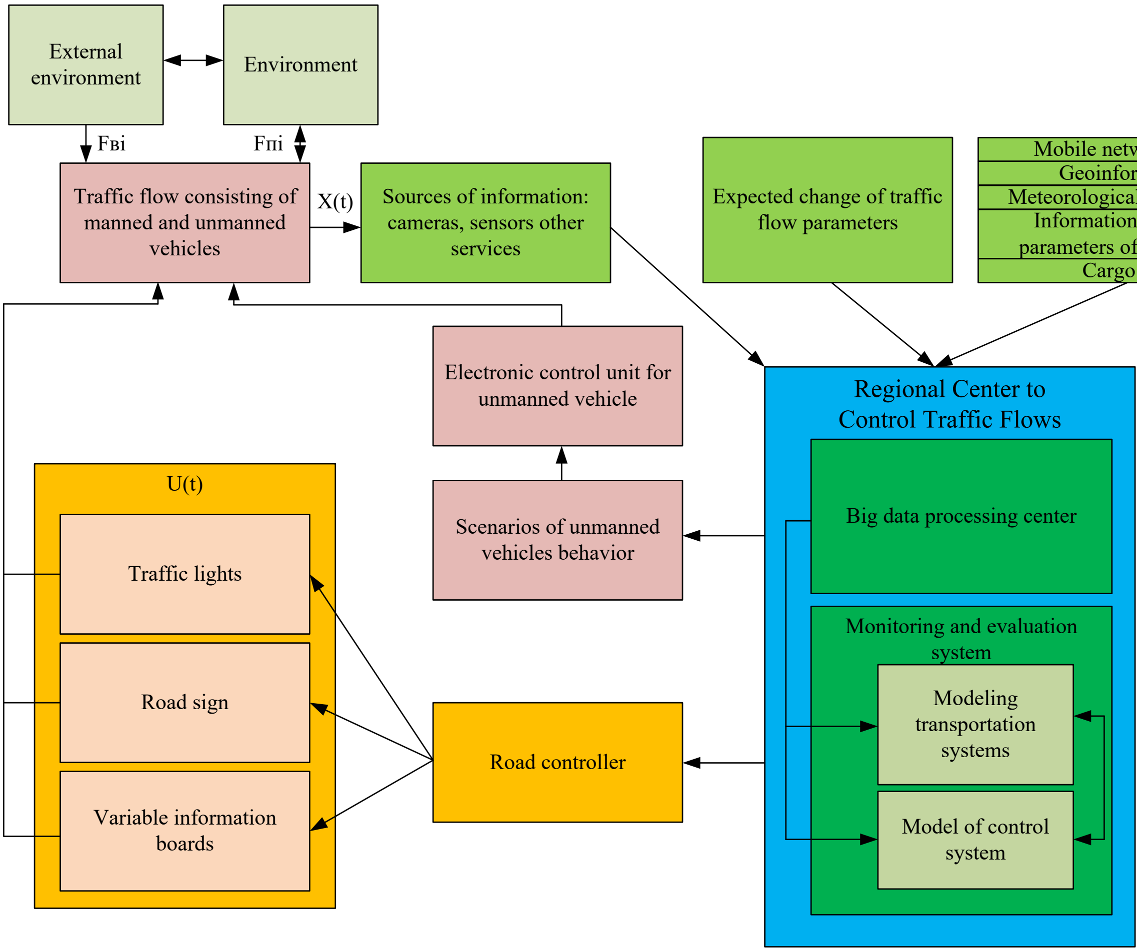

Fig. 7.
Structural model to control traffic flow
Here X(t) is the state of the system (traffic flow parameters), U(t) is control parameters and F are measured parameters of environment effects

Depending on the detected deviations of the characteristics of traffic flow characteristics and based on some quality criteria, the control system (which is a part of RCCTF) changes modes traffic signaling modes and / or information on the managed road signs (including adaptive management) to achieve optimal values of the observed criteria. Depending on the task to be solved, it is possible to use various system quality criteria (partial system security criteria, just-in-time principles and other logistic principles). Assumes using a system of traffic controllers switching traffic signals and traffic signs symbols. In addition, the necessary information for road users has to be constantly placed on the variable information boards.
RCCTF also analyzes ecological and economic system of the region, providing algorithms to systematize heterogeneous data and their integration in uniform system and transfer them to Service 1 “Modeling and Managing Traffic Flow of Manned Vehicles” and Service 2 “Information Support for Drivers”.
Service 1 contains transport simulation models to provide optimal impacts on traffic flow, to develop conflict-free and smooth transportation corridors, to control an access of vehicles to these transportation corridors. Simulation modeling of traffic flows adequately reflects the behavior of traffic flows. Existing transportation models are usually used to test

proposing organizational solutions, allowing to evaluate alternative projects before their implementation to traffic management activities. Created transportation models involve so-called digital twins of vehicles and the road network, which can be used to analyze their operation and control, as well as to optimize the parameters of the traffic flow and service in real time. It is also possible to analyze the effectiveness of traffic control in real operating conditions and accurately forecast it. It is expected that it will reduce delays and the time of communication, as well as the cost of time of vehicles, drivers and passengers (*Kadasev, 2018*).
Service 2 informs drivers about the current and forecasting traffic situation, congestion, provides the information about routing, taking into account the environmental situation in the region. Data depicting current traffic situation are delivered with sensors, cameras, mobile networks and other services. To predict the road situation, main factors affecting traffic flows are used: socio-economic statistics (population and level of employment), statistics on using personal and public transport, changes in the road network, as well as the cost estimate of drivers and passengers time.

4. Conclusion

Existing intelligent transportation systems in the Russian Federation are a semi-structured set of applications for solving particular emerging problems of manned vehicle flow control in certain parts of the transport network. Study proposes a conceptual model of controlling structure for the regional intelligent transportation and logistics system. The regional module of such system within transportation corridors in a single information space can contribute to the reduction of accidents, improve transportation efficiency, provide a higher level of transport security and improve environmental performance.

THE USE OF SOCIAL NETWORKS IN LOGISTICS COMPANIES IN SERBIA

Vladimir Ilin[1] 1, Dragan Simić2, Nenad Saulić3, Marko Veličković4

1,2,3,4 University of Novi Sad, Faculty of Technical Sciences, Department of Traffic Engineering, Novi Sad, Serbia

Abstract: The aim of this paper is to analyze the use of social networks in logistics companies in Serbia. We used the available data from the National Bureau of Statistics of Serbia to identify trends of the use of social networks in (1) small, medium-sized and large logistics companies in Serbia and in (2) logistics companies in different geographical regions of Serbia. After that, we conducted a survey analysis to identify the number of logistics companies in Serbia that used social networks in 2017 and to compare our results with the data provided by the National Bureau of Statistics of Serbia. Furthermore, we have identified the correlations between the percentage of employees with a university degree and the number of computers per company and the intention of logistics companies to use social networks. The obtained results indicate that the percentage of employees with a university degree and the intention of logistics companies to use social networks have statistically significant and positive correlation.

Keywords: information and communication technologies, social networks, logistics companies in Serbia.

1. Introduction

Information and communication technologies (ICTs) have been regularly used in today's businesses, particularly in logistics (Ilin and Simić, 2012; Ilin and Groznik, 2013). In the new economic and social environment, the understanding of the developments and transformations undergone by ICTs with the advancement of social networks and Web 3.0 technology is vital because of the influence of recent innovations in the competitiveness of organizations (Garrigos-Simon et al., 2012).

The online information environment has evolved from a traditional one-way flow of information (from sender to receiver) to a two-way flow of information (from sender to receiver and vice-versa). The former refers to Web 1.0 and the letter refers to Web 2.0. The further evolvement of the web towards Web 3.0 relies on intelligent, contextual decisions of the semantic web, along with the Internet of Things paradigm which requires different devices to be connected to be able to create a large stream of data. In supply chains, Web 3.0 capabilities could be applied for the optimization of the distribution flow of trucks or cargo ships (Harris et al., 2015).

Development of semantic web technologies and different social networks have a potential to create new business environments. According to some predictions, the attention of individuals and companies towards social media, and particularly towards social networks is growing exponentially (Rutsaert et al., 2013). Social networks are widely available and mostly free medium that allows individuals and/or companies to establish communication and cooperation. Recently, the fast development of the Internet use – above all Web 3.0 and online social networks has increased interest in the marketing sector. Many companies have decided to incorporate social marketing (Marketing via social networks) to support their commercial activities (Mata and Quesada, 2014).

In logistics, social networks represent the medium through which manufacturing companies, distribution companies, customers and other stakeholders exchange business information, and thus improve existing cooperation and increase the number of business partners they are cooperating with. Social networks allow logistics stakeholders to be part of global logistics networks, which is the precondition of efficient and effective supply chain (Gligor, 2014). Taking a social network potential to provide sharing of real-time information between all stakeholders in supply chains as well as coordination and cooperation allow stakeholders to better map supply chains structure and to better understand network characteristics and interrelationships between members (Wichmann and Kaufmann, 2016). In addition, Web 3.0 and social networks have a potential to be applied for the identification of objects in supply chain.

According to the statistic portal Statista (2017), the number of monthly active social network users in Serbia is projected to reach 3,5 million individuals in 2022. This would be an increase of over 470.000 new users from 3,03 million users in 2016. However, the statistic portal made no predictions for the use of social networks in companies in Serbia. According to the National Bureau of Statistics of Serbia (2017), all surveyed logistics companies in Serbia had the internet connection in 2017. Simultaneously, 85,5% of surveyed logistics companies in Serbia used a broadband internet by portable devices, such as tablets, laptops, and smartphones. The internet connection is the precondition for the use of social networks, and the broadband internet connection facilitates the use of new ICT concepts in business, such as big data and Internet of Things.

The aim of this paper is to analyze the use of social networks in logistics companies in Serbia. We used the available data from the National Bureau of Statistics of Serbia to identify trends of the use of social networks in (1) small, medium-sized and large logistics companies in Serbia and in (2) logistics companies in central Serbia, AP Vojvodina and Belgrade. After that, we conducted a survey analysis to identify the number of logistics companies in Serbia that used social networks in 2017 and to compare our results with the data provided by the National Bureau of Statistics of Serbia. Additionally, we have examined the correlations between the percentage of employees with a university degree and the number of computers per company and the intention of logistics companies to use social networks.

[1] Corresponding author: v.ilin@uns.ac.rs

The rest of the paper is organized as follows. After the introduction, in section 2 the use of public and professional network services in logistics is introduced. The use of social networks in different industries in Serbia is presented in section 3, while the use of social networks in logistics industry in Serbia is presented in section 4. In section 5 we presented the results obtained from a survey analysis in logistics companies in Serbia and we compared them with the results presented in section 4. Concluding remarks and directions for future work are given in the last section.

2. Public and Professional Network Services In Logistics

Public social networks, such as Facebook and Twitter, bring revolutionary changes in the way how individuals communicate. Public network services could be used in the transport and logistics environment to facilitate instant communications between various stakeholders, such as manufacturers, suppliers, producers and others. Professional network services, such as LinkedIn, Xing and Yammer bring revolutionary changes in the way how companies communicate. For example, companies such as Tesco, Vodacom, and LG Electronics have started to use professional network services for communication between business partners. For instance, management in Tesco use Yammer to share examples of best practices, often by posting photos as well as to share messages and ask for feedback (Tesco Annual Report 2012).

Together with professional network services, blogs and wikis have a great potential to improve business communication between stakeholders in supply chains. The blogs and wikis are primarily used to strengthen cooperation between stakeholders. The general concept of a wiki is an open platform with a self-organization of the content (Ebersbach and Glaser, 2005). This might be used to display information relevant for identification and selection of potential suppliers. Blogs are publications written by individuals or groups on specific topics that are accessible to stakeholders from various business categories. They can also be used for identification of new suppliers. Schrödl (2012) used a metric classification to perform an assessment of advantages that professional network services, blogs and wikis have on the strategic development of supply chain networks.

Table 1

Assessment of the use of digital social networks in procurement process

Procurement process	Characteristics	PNS	B	W
Identification of suppliers	Search Capabilities	4	3	4
	Integration of self-information	5	4	4
	Usage of classification standards	3	2	2
Selection of suppliers	Integration of additional information	4	4	4
	Integration of external rating information	4	4	2
Qualification of suppliers	Maintaining linkage	5	1	1
	Distribution of information updates	5	4	4
	Establishment of closed groups	5	3	1

Note: PNS - professional network services; B - blogs; W - wikis; 1 - inapplicable; 2 - less likely; 3 - neutral; 4 - limited use; 5 - very likely.

Source: (Schrödl, 2012)

Professional network services provide a high potential to be used in all three segments of the procurement process, particularly for the identification of suppliers and their qualification (Table 1). Blogs are the most suitable to be applied for the selection of suppliers, whereas wikis have a potential to be used for the identification of suppliers (Table 1).

3. The use of Social Networks in Different Industries in SERBIA

In 2010, Serbia developed the strategy for the development of an information society (Serbian IT strategy, 2010) with the objective of being capable of obtaining the adaptation and usage levels that are currently possessed by the EU countries. The Serbian IT strategy reveals that the development of e-business and overall electronic communications are the basis for the progress of an information society (Ilin et al., 2017). Since web-based applications are nowadays necessary for the use of almost all social networks, the main aim of the Serbian IT strategy correlates with the development and the recent extensive use of social networks in companies from different industries in Serbia. According to the National Bureau of Statistics of Serbia, 63,3% of firms from different industries in Serbia used social networks in 2017, compared to 63,2% of firms in 2016. We analyzed the available data from the National Bureau of Statistics of Serbia[3] to identify trends of the use of social networks in companies from different industries in Serbia for the period from 2013 to 2017 (Figure 1).

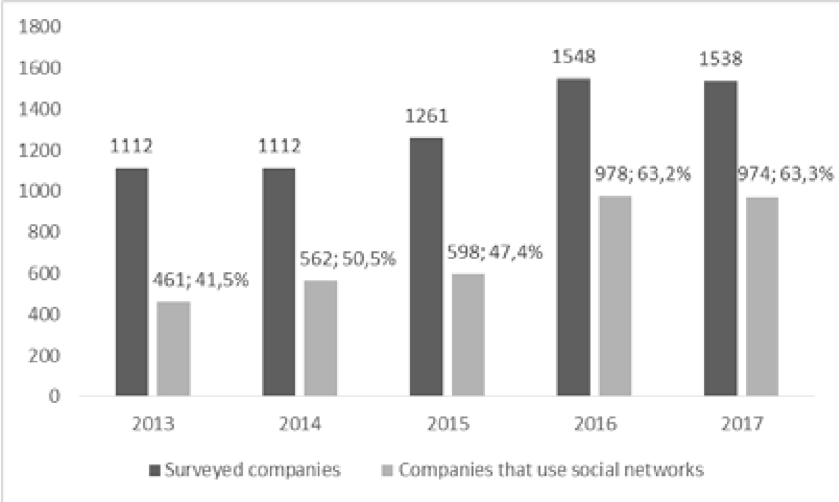

Fig. 1.
The use of social networks in companies from different industries in Serbia

The presented data show that there is a positive trend of the use of various social networks in companies from different industries in Serbia (Figure 1). It can be noticed that there is an increase of 21,8% of surveyed companies that used social networks in 2017 compared to 2013. The more detailed visualization of the diversity of the use of different social media in companies from different industries in Serbia is shown in Table 2.

Table 2
The diversity of the use of social media in companies from different industries in Serbia

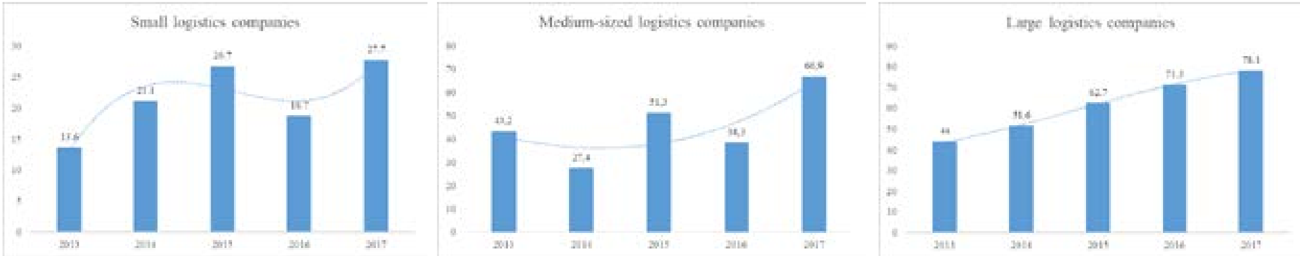
	Year				
	2013	**2014**	**2015**	**2016**	**2017**
Social networks	**Percentage**				
Facebook, Twitter, LinkedIn, Xing, Yammer	30,8	36,6	37,4	48,6	48,7
Increase (+) / decrease (-)*		+ 4,8	+ 0,8	+ 11,2	+ 0,1
YouTube, Flickr, Picasa	10,7	13,9	10	14,6	14,6
Increase (+) / decrease (-)*		+ 3,2	- 3,9	+ 4,6	/
Online encyclopedia	**Percentage**				
Wikipedia	6,2	5,1	7.5	8,3	6,8
Increase (+) / decrease (-)*		+ 0,9	+ 2,4	+ 0,8	- 1,5

*Note: * Increase and decrease are measured for the observed year compared to the previous year.*

Public and professional network services (Facebook, Twitter, LinkedIn, Xing and Yammer) attract new companies from different industries in Serbia each year (Table 2). However, this is not the case with some other social networks (YouTube, Flickr, Picasa) and online encyclopedia (Wikipedia).

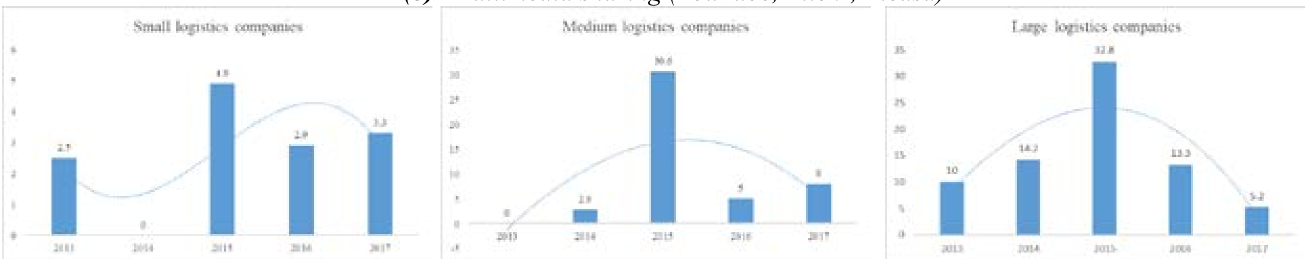
4. The use of Social Networks in Logistics Industry in Serbia: an Official Statistics

We used the available data from the National Bureau of Statistics of Serbia (http://www.stat.gov.rs) to conduct analysis regarding the use of social networks in logistics companies in Serbia and to identify trends of the use of social networks for the period from 2013 to 2017. The traffic and warehouse companies are observed as logistics companies. The analysis is performed by two criteria: the size of the logistics company and the geographical region where the logistics company is located. The use of different social networks and online encyclopedia in small, medium-sized and large logistics companies in Serbia is presented in Figure 2. Classification of logistics companies in Serbia has been performed in the following way. Small logistics companies are those that have more than 10 employees and less than 50 employees, medium-sized logistics companies are those that have more than 49 employees and less than 250 employees and large logistics companies are those that have more than 249 employees. The use of different social networks and online encyclopedia in logistics companies in central Serbia, AP Vojvodina and Belgrade is presented in Figure 3.



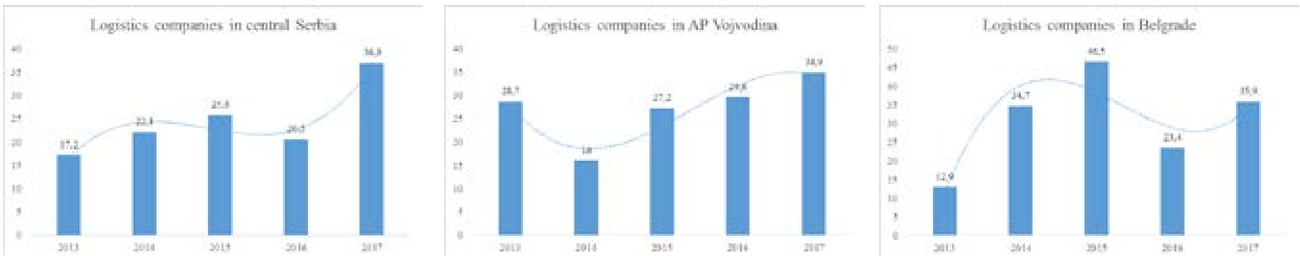
(a) Public and professional network services (Facebook, Twitter, LinkedIn, Xing, Yammer)

(b) Multimedia sharing (YouTube, Flickr, Picasa)

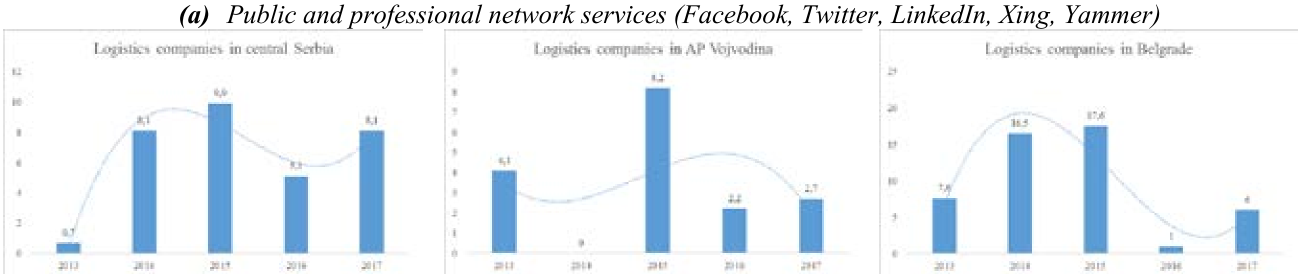


(c) Online encyclopedia (Wikipedia)

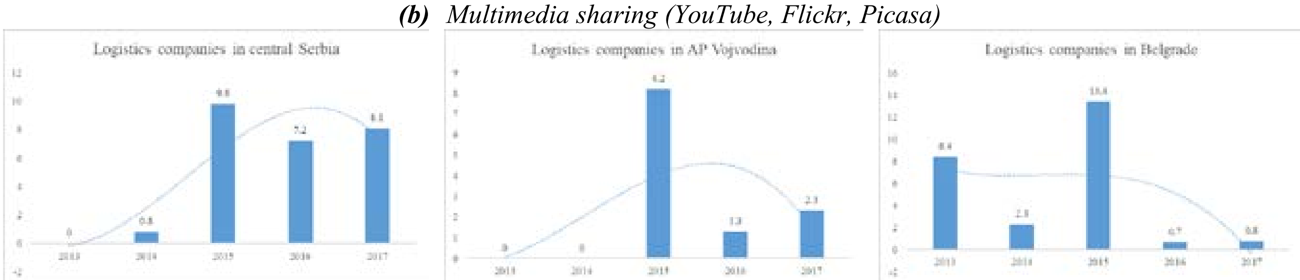
Fig. 2.
The use of social networks and online encyclopedia in small, medium-sized and large logistics companies in Serbia



(a) Public and professional network services (Facebook, Twitter, LinkedIn, Xing, Yammer)



(b) Multimedia sharing (YouTube, Flickr, Picasa)



(c) Online encyclopedia (Wikipedia)

Fig.3.
The use of social networks and online encyclopedia in logistics companies in different geographical regions of Serbia

Public and professional network services (Facebook, Twitter, LinkedIn, Xing, Yammer) have noticeable growth of the number of small, medium-sized and large logistics companies in Serbia that used social networks in 2017 compared to the period from 2013 to 2016 (Figure 2a). The use of multimedia sharing (YouTube, Flickr and Picasa) as well as online encyclopedia (Wikipedia) was declining in small, medium-sized and large logistics companies in Serbia in 2017 compared to 2015 and/or 2016 (Figure 2b and Figure 2c). The exception of previously noticed trend is the use of multimedia sharing in large logistics companies. It can particularly be noticed that the use of Wikipedia in small, medium-sized and large logistics companies in Serbia reached the peak in 2015 (Figure 2c).

Public and professional network services (Facebook, Twitter, LinkedIn, Xing and Yammer) have noticeable growth of the number of logistics companies in central Serbia and AP Vojvodina in 2017 compared to the period from 2013 to 2016 (Figure 3a). The use of public and professional network services in logistics companies in Belgrade was at the pick in 2015. The use of multimedia sharing (YouTube, Flickr and Picasa) as well as online encyclopedia (Wikipedia) was declining in logistics companies in central Serbia, AP Vojvodina and Belgrade in 2017 compared to 2015 and/or 2016 (Figure 3b and Figure 3c).

5. The use of Social Networks in Logistics Industry in Serbia: a Survey Analysis

In order to confirm identified trends in Section 4 we conducted a survey analysis in logistics companies in Serbia and compared the obtained results from our research with the results presented in the previous section. The empirical data were collected through a mail survey during 2017. The potential respondents in this study were obtained from a website: http://logistikausrbiji.rs. The final sample included 23 logistics companies that use social networks and 7 logistics companies that do not use social networks. According to the authors' research, 76,7% of surveyed logistics companies used social networks in 2017 compared to 63,3% of surveyed logistics companies in the same year according to the National Bureau of Statistics of Serbia. The identified difference between two studies can be explained by a lower number of potential respondents that are included in the survey analysis conducted by the authors. The sampling data were stratified by size and respondents' title (Table 3).

Table 3

The characteristics of the sampling firms and respondents (N = 30)

Category	Percentage
Number of employees	
10-49	43,3
50-249	36,7
> 250	20
Respondent title	
Non-IS managers	76,7
IS managers	23,3

Furthermore, we have examined the impact of two parameters on the intention of logistics companies in Serbia to use social networks (labelled as USN). The first parameter is the percentage of employees with a university degree (labelled as PoUD) and the second parameter is the number of computers per company (labelled as NoC). We used software Origin 2016 for the calculation and visualization of Pearson correlation coefficients between USN, PoCD and PoCD. The correction matrix is presented in Table 4. Only correlation between USN and PoCD is found to be statistically significant.

Table 4

Correlation matrix for likelihood of social network use in logistics companies

Parameters	PoUD	NoC	USN
PoUD	1		
p-value	-		
NoC	-0,073	1	
p-value	0,703	-	
USN	0,397*	0,168	1
p-value	0,030	0,376	-

*Note: * p-value < 0,05; ** p-value < 0,01 (two-tailed).*

The scatter matrix with confidence ellipse of 95% is presented in Figure 4. The presented results confirm that there is a positive correlation between USN and PoCD.

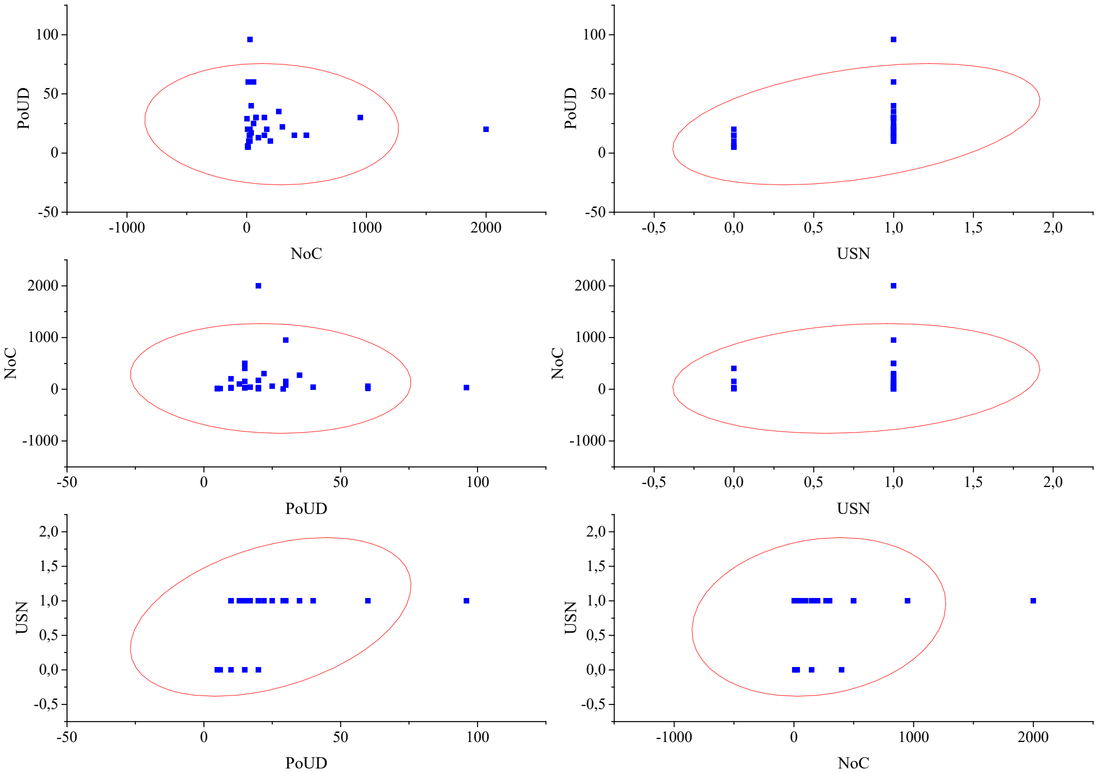


Fig.4.
Scatter matrix with confidence ellipse of 95% for likelihood of social network use in logistics companies

It can be noticed (Table 4 and Figure 4) that the percentage of employees with the university degree and the intention of logistics companies to use social networks have statistically significant and positive correlation (p-value < 0.05). It means that if a logistics company in Serbia has a higher percentage of employees with a university degree, the use of social networks in the company will be more likely. However, the number of computers per company and the intention to use social networks in logistics companies do not have statistically significant correlation (p-value > 0.05). Therefore, if the logistics company in Serbia invest money in the procurement of new computers that decision will not impact the intention of the company to use social networks.

6. Conclusion and Future Work

In this paper we performed an analysis of the use of social networks in logistics companies in Serbia. First we identified trends of the use of public and professional network services, multimedia sharing and online encyclopedia in (1) small, medium-sized and large logistics companies in Serbia and in (2) logistics companies in central Serbia, AP Vojvodina and Belgrade based on the data provided by the National Bureau of Statistics of Serbia. After that, we conducted a survey analysis to confirm the identified trend of the use of social networks in logistics companies in Serbia in 2017. The obtained result indicates that logistics companies in Serbia use extensively social networks in their businesses. One plausible explanation of the obtained finding is that the use of social networks in logistics companies may be triggered by the increased awareness of the significance of ICT development through numerous EU supported projects, strategies, initiatives and public programs in Serbia. A second plausible explanation is that the use of social networks is free and widely available to companies from different industries. Future research could examine the causalities of identified trends of the use of social networks in logistics companies in Serbia.

Furthermore, we have examined the impact of the percentage of employees with the university degree and the number of computers per company on the intention of logistics companies to use social networks. The obtained results indicate that the percentage of employees with the university degree and the intention of logistics companies in Serbia to use social networks are statistically significant and positively correlated. It is also found that the number of computers per company is not relevant parameter when logistics company in Serbia decides to use or not to use social networks.

In order to monitor further process of ICT development of logistics companies in Serbia similar research should be performed with the focus on some other technologies and information systems, such as radio-frequency identification technology, barcode technology, warehouse management system and transportation management system. The number of parameters whose impact on the intention of logistics companies to use social networks is examined should also be increased.

CFD SIMULATION OF A PLANING HULL

Adrian Caramatescu[1]**, Costel Iulian Mocanu**[2]
[1,2] *"Dunărea de Jos" University of Galați, România*

Abstract: The availability of the robust commercial Computational Fluid Dynamics (CFD hereafter) software and high speed computing has led to increased use of CFD for solution of fluid engineering problems across industry and boat building is no exception. In the recent years, fast composite planing hulls show an increasing interest in the scientific research field. An extensive range of both civil and military applications require precise data for loading forces acting on the hull surface and the shape of the wetted area. The current study presents a numerical simulation of the free surface flow around the hull of a composites power boat used on the Danube River for several speed values ranging between displacement and planing, including the transition period. A general numerical method to predict planing behavior of a boat is presented in the paper, using the NUMECA/FineMarine commercial code to compute the flow solution on a multiblock, high-performance parallel computing method. The RANSE VOF solver computation method is employed to evaluate the flow field in planing condition and to estimate the pressure field on the hull surface. The flow around planing hulls involves different and complex physical phenomena such as thin spray flow, wave breaking, air trapping and turbulent boundary layer. In this particular case, an inverted keel design was used in order to achieve a lower resistance of the hull due to the air entrapment in the semitunnel. The phenomena is captured well and detailed in the illustrations. In order to validate the results, the trim angle calculated by the CFD software is compared with the trim measurement conducted in full scale experiment.

Keywords: CFD, planing hulls, full scale experiment, validation, composites hull, river boat.

1. Introduction

The accelerated development of computing and the use of simplified numerical methods to solve the problems of fluid flow alongside a ship's hull create the premises for CFD methods to be a powerful verification tool in naval architecture. Whether it comes to leisure boats, commercial applications or naval operations, planning hulls show a constant interest since their early development in the end of the 18th century. The resistance of the hull is a problem solved by an analytical method in a pretty simple approach, with reasonably accurate results (Savitsky, 1969). The hull geometry particularities however present an important aspect in the matter of trim estimation and with that the prediction of the planing speed estimation might slightly differ, even when using the improved versions of the initial method (Savitsky et al, 2007). Recent CFD studies prove a proper evaluation of the trim and resistance estimation (Caramatescu, 2016)

On another approach, the dynamic pressure estimation and its distribution map on the wetted surface is a complex problem that cannot be solved in an analytical approach. Due to different phases involved, the free surface position is difficult to predict. Pressure distribution is the load a hull of the boat is subjected to, and usually that is roughly evaluated by the register rules or more recently by the ISO standards.

This paper presents the ability of the software to perform simulations of a complex hull form in preplaning conditions (Fr=0.57) to high speed full planing conditions (Fr=1.71).

2. Hull Geometry and Simulating Conditions

The craft that is the subject of this CFD simulation is a leisure composite craft, produced in Romania and used on the Danube river. A particular shape of the hull is used by the manufacturing company (Plasma SRL) in order to acheive a shallow draught - especially important in the Danube Delta. The hull presents an inverted keel on a width of 550 mm, forming a semitunnel with a depth of 50 mm. This section also seeks to reduce the frictional resistance at high speed by creating an air cushion therefore reducing the wetted surface.

The simulations are carried out for a range of hull speeds between 4 m/s corresponding to full displacement to 12 m/s when the boat is in full planing condition, declared as the maximum speed of the boat in the corresponding loading condition.

The main particulars of the craft are presented in Table 1; in Figure 1 there are presented the body lines of the hull, while in Figure 2 there is shown a rendering of the hull shape.

Table 1
Main particulars of the boat used in the CFD simulation

Length over all	5.65 m
Beam	1.78 m
Depth	0.70 m
Empty draft	0.27 m
Hull weight	220 kg
Max displacement	600 kg
Propulsion power	40 CP

A 3D rendering of the CAD model used in the CFD simulation

3. CFD Simulations

The numerical code NUMECA FineMarine was used to perform the planing simulations. The solver uses RANSE VOF computation method to evaluate the final position of the hull for each simulation speed, having the trim and heave free while the other motions are blocked. To discretization of the hull surface was done using unstructured monobloc cartesian grid. The topology of the grid is H-H type, composed of adjacent hexahedral elements. Together with the computing field, an average of 2.5 million cells were generated for each of the travel speed values. The applicable boundary conditions are:

- constant velocity equal to the speed of the ship moving at entry into the computing field (upstream);
- sliding conditions at the exit of the computation field (downstream), as well as for the outer boundaries of the domain, on the free surface and in the symmetry plane;
- on the surface of the body is required the adhesion of the fluid to the wall (no slip).

Grid refinement is done by dividing the cells so that a greater density of cells is present in areas of interest such as the free surface in the contact area with the hull, spray rails, intersection of the transom with the bottom (Battistin *et al,* 2003). In Figure 3, there can be seen the refinement of the bow and stern area for the simulation ran at 8 m/s.
For the purpose of accurately modeling the turbulent layer and taking into account the available processing power, the value of the non dimensional wall function coefficient was chosen y+=5.

3.1. Computational Strategy

A number of studies have addressed the issue of solving the numerical flow around a planing hull based on the theory of potential flow (Wackers *et al,* 2009), (Ghasemi *et al,* 2009) but in these cases the disadvantage is that these methods can be used only in simulations for very high velocities, and cannot reproduce the formation of waves and spray curtains that appear. The subsequent solutions that emerged were based on new approaches to large Froude numbers, characterized by multiple phases. In these situations, the components of viscous resistance and pressure resistance are non-linearly correlated with hydrodynamic lifting forces and trim angle (Battistin *et al,* 2003), (Yumin *et al,* 2012), (Azcueta, 2003). The calculation model used by simulation software used (Numeca FineMarine) is based on the Reynolds-Averaged Navier Stokes equations (RANS) for hydrodynamic performance estimation, the VOF method for estimating the free surface of an incompressible and non-miscible liquid with the second fluid (Caponnetto, M. 2001), (Queutey *et al.,* 2007) and the turbulence model k-omega.
The equations describing fluid flow alongside a body moving in this fluid are the continuity equation and the Navier-Stokes equations. These equations model the flow of fluids by viscosity, considering the fluid as Newtonian and the viscous forces being directly dependent on the velocity gradients. These equations together form a system of partial nonlinear equations. Considering water as an incompressible liquid with negligible density variations, the two equations can be written as:

$$\frac{\partial U_i}{\partial x_i} = 0$$

$$\rho\frac{\partial U_i}{\partial t} + \rho\frac{\partial\left(U_iU_j\right)}{\partial x_j} = \rho R_i + \frac{\partial \sigma_{ij}}{\partial x_j}$$

where U_i are the instantaneous components of fluid velocity in the cartesian coordinate system x_i, ρ is the density of the water, t is time and σ_{ij} is the tensor of total tensions. One of the most used turbulence models currently applied is the k-omega model, originally proposed by Wilcox in 1998 and then improved in 2008. In this turbulence model, two differential equations are used for two variables, k and ω, the first describing kinetic energy and the second specific rate of kinetic energy conversion into internal thermal energy. The formulation of the two variables are:

$$\frac{\partial k}{\partial t} + U_i\frac{\partial k}{\partial x_i} = \tau_{ij}\frac{\partial u_i}{\partial x_j} - b^*\kappa\omega + \frac{\partial}{\partial x_i}\left[(\nu + s^*\nu_T)\frac{\partial k}{\partial x_i}\right]$$

$$\frac{\partial \omega}{\partial t} + U_i\frac{\partial \omega}{\partial x_j} = a\frac{\omega}{k}\tau_{ij}\frac{\partial u_i}{\partial x_j} - b\omega^2 + \frac{\partial}{\partial x_j}\left[(\nu + s\nu_T)\frac{\partial \omega}{\partial x_i}\right]$$

To define the free surface demarcation area, a numerical method called Volume Volume Fluid (VOF) is used. In the sense of this method, based on a fractional volume function α the fluid density and viscosity are modified as follows:

$$\mu = \mu_{water} + \mu_{air}(1-\alpha)$$
$$\rho = \rho_{water} + \rho_{air}(1-\alpha),$$

where μ_{water} and μ_{air} are the dynamic viscosity of water and air and ρ_{water} şi ρ_{air} are the densities of water, respectively air. The position of the free surface of the liquid is governed by the volumetric fraction transport equation, and this is solved for each discreet volume cells in the calculation range:

$$\frac{\partial \alpha}{\partial t} + \nabla(\alpha U) = 0,$$

where $0 \le \alpha \le 1$, U is the speed of the flow and ∇ is the cell's volume.
Solving the equation we can obtain 3 results:

$\alpha = 0$	if the cell si full of air;
$\alpha = 1$	if the cell is full of water;
$0 < \alpha < 1$	if the cell contains free surface.

4. Results and Discussions

Pressure distribution calculated on the wetted surface is represented graphically in the series of pictures shown in Figure 4.

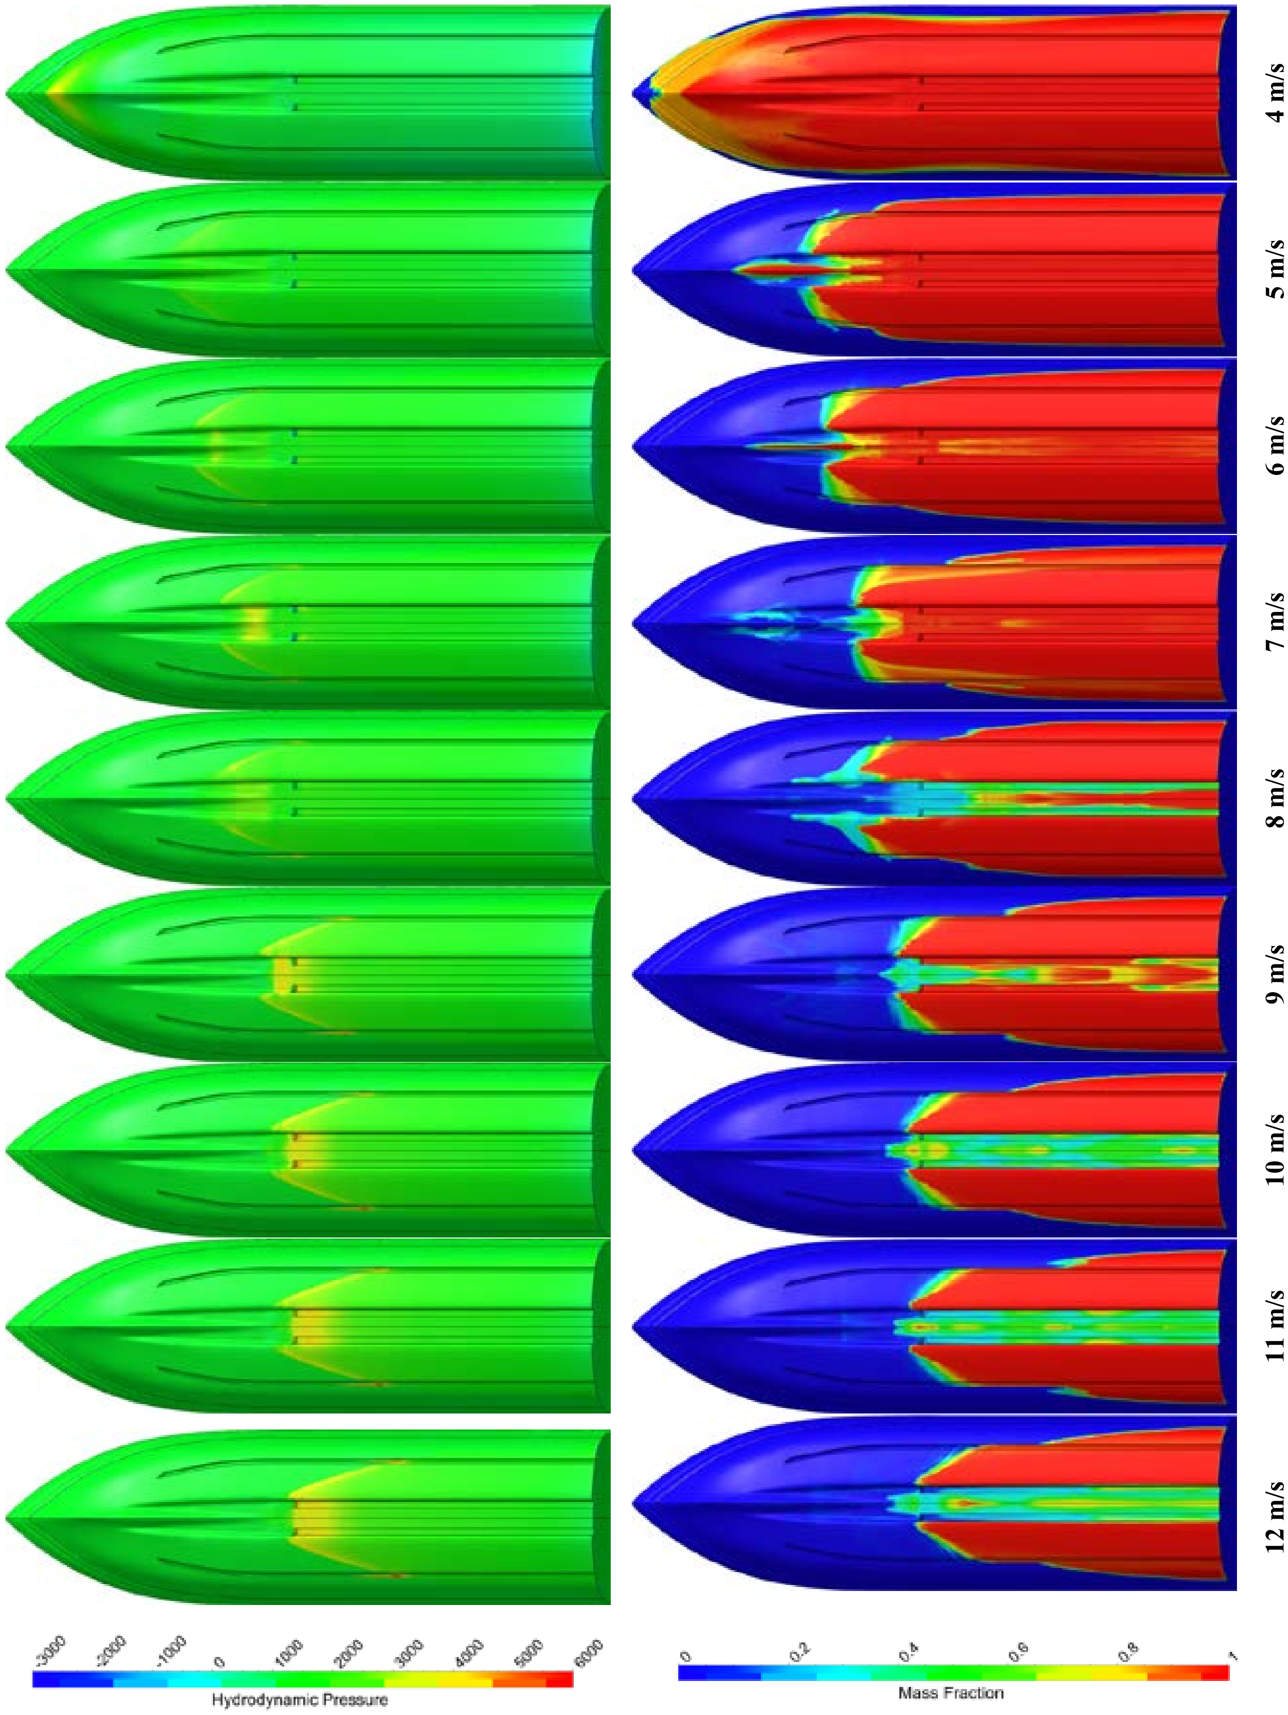

Fig. 4.
Pressure distribution (N/m^2) as well as volume fraction for each speed

As it can be observed, the largest pressure gradient is recorded at the stagnation point, at the entry of the hull into the water. This large pressure area is also properly predicted by the register rules as well as the ISO standards. Numerical results of the pressure calculated in each of the hull surface cells can be extracted and transferred to a FEM software via a polynomial interpolation.
As from the air entrapment point of view, the hull design creates the expected air cusion in the semitunnel, delivering the frictional resistance reduction. Mass fraction maps show the initial formation of the air vortices at 8 m/s, while at 10 m/s the entire bottom of the boat within the semitunnel is separated from the water surface. A different rendering with the same phenomenon can be seen in Figure 5 below:

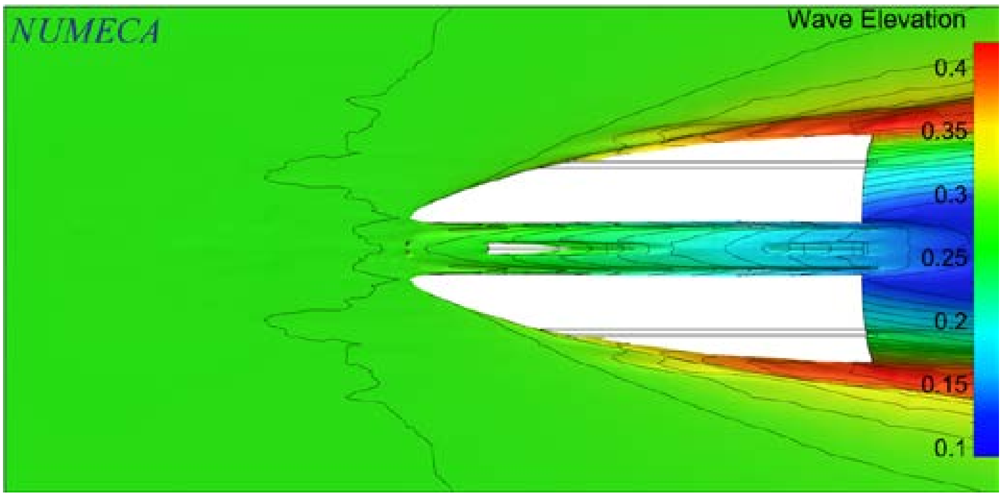

Fig. 5.
Bottom view of the hull showing the free surface depth isocurves. Wetted hull is represented in white for better contrast

5. Experimental Validation

Trim angle measurements have been conducted for each of the hull speed values considered in this simulation, using a full scale boat, equipped with an inclinometer, model Turck B2N45H-Q20L60-2LI2-H1151, connected to a measurement bridge Spider 8. The trials have been conducted in calm water, so as not to viciate the results with the effect of the encountered waves. Afew aspects of the trials are represented in Figure 6 below.

Fig. 6.
Experimental trials conducted with full scale model. The installation of the inclinometer in the bilge (middle) and the electronic circuit built for the data acquisition (right)

Trim angle measurements recorded during the trials have been compared with the Savitsky (1964) estimation and the CFD calculations, showing a reasonable error between the CFD and experiment, while Savitsky method shigtly underpredicts the trim for the low speed values and overpredicts the trim angle for the range of speeds comprised between 5 to 10 m/s. The reason of errors for the low speed values is due to inaccurate results of the method for non planning speed values, while the overprediction errors are due to the geometry particularities not accounted for by this simplified method, as the semitunnel.

Table 2
Computed trim and experimental data

v (m/s)	θ_{EFD} (°)	θ_{CFD} (°)	$\theta_{Savitsky}$ (°)

Trim variation

6. Conclusions

As the numerical simuations seem to be a tool with an increased usage in the field of naval architecture, complex geometries can be studied in the stage of early design, allowing the engineers to perform detailed analyses of flow fields around a planing hull. Full scale experimental data provides a valuable pool of benchmark values with wich the numerical simulations can be compared and properly adjusted. While the variety of the software solutions used for this urpose increases, a numerical valdation must be conducted each time this is possible.
The comparative evaluation of the values of the trim angle of the experiment and of the CFD analysis shows a good correlation, with variations between 0.3 and 2.8 percent, with a good tracking of the experimental values. The Savitsky method evaluates the angle of trim using an empirical and rapid calculation but has an error rate between 0.4 and 22.8 percent from the experimental values. The overall trend of the variation of trim angle is the same, increasing during the transition period and at the beginning of the planing, then stabilizing and decreasing as the speed increases. At the estimated start of planing, at 5 m/s, the values calculated for the trim are very close, which means that the planing start point is very well estimated by the Savitsky method.

Acknowledgements

The authors would like to acknowledge the contribution of the “Dunarea de Jos” University of Galati PhD programme that provided the research facilities for both experimental and computing researches conducted. Nevertheless, the boatyard Plasma SRL Galati is to be acknowledged for supplying the fully equipped test boat used on the experiment and its geometry.

[1] *Danube Delta National Institute for Research and Development of Tulcea, Romania*

Abstract: Natural mineral aggregates transported by the Danube River are generated by the natural disintegration of the rocks under the action of frost and repeated thawing and their rollover to torrential waters, streams and the rivers, which are used in the manufacture of concrete (ballast, gravel, and sand). The target area of this study is located on the Danube River between Km 521–Km 524. In this sector, it takes place the exploitation of mineral aggregates. From this perspective, a study will be conducted through which it will be seen whether those operations interfere with the navigation on the Danube River. The study is performed using GIS applications and assessing the influence of the dredging executed in this perimeter on the movement of the ships and boats on the river. On the other hand, it has to be highlighted that at different times of the year, on the Danube different sand islands of various sizes are formed, making very difficult the navigation of the ships. Their shape and dimensions are constantly changing, under the influence of the water level changes, the speed of the water flow and the waves caused by the crafts passing on the Danube. From this perspective, the present work follows the way in which these aggregate exploits influence the appearance of the sand islands along the Danube, appearance which is very dangerous for the inland navigation. The study is based on 'in situ' measurements performed in two different recent time periods, namely during the autumn of 2016 and continuing later in the summer of the following year, 2017. The results are obtained by processing the data using the GIS methods and representing a comprehensive picture of the sector analyzed in different viewing modes. All these aspects present a special interest for a safer navigation on the Danube River.

Keywords: inland navigation, Danube River, exploitation, measurements, GIS.

1. Introduction

In Romania, the Danube River forms the southern border of the country with Bulgaria. Approximately 38% of the length of the river and the most important part as flow and navigation, including its mouths, are located in the Romanian territory. The lower course of the Danube runs at a distance of 1,075 km between Bazias and Sulina, making a border with Serbia 235, 5 km, Bulgaria 469, 5 km, Republic of Moldova 0, 6 km and Ukraine 53, 9 km. Because the Danube crosses a multitude of natural regions, the lower course is divided into 5 sectors, as follows: Carpathian Defile 144 km, South-Pontic Sector 566 km, Pontic Oriental Pond Sector 195 km, Predobrogean Sector 80 km and the Deltaic Sector 90 km (Banescu *et al.*, 2018).
The Danube River collects most rivers in Romania except those in Dobrogea, which flow into the Black Sea.
In the evolution of the hydrographical network of the territory of the lower basin of the Danube, two stages can be distinguished: the pre-quaternary stage, when the relief has been consolidated and the main water accumulations have formed; the quaternary stage when the current hydrographic network developed on the old terraces took place. At this time, the lower course of the Danube stretches between the upstream Bazias and the Black Sea, draining the waters from the Carpathians and the Balkans, extending over a length of 1075 km (Ivan *et al.*, 2012).
The main Danube course on this sector is located at the beginning west, northwest, east, southeast, to the front of Calafat, where it acquires the west-east orientation that is maintained until Zimnicea. Between the localities of Zimnicea (where the Danube reaches the southernmost point, 43^0 37 'north latitude and 25^0 25' east longitude) and Silistra, the Danube course is oriented southwest and northwest. Downstream of Silistra, Dobrogea hills oblige the Danube to change its orientation from the east to the north, describing a very large curve. This orientation is maintained up to the city of Galati, where, due to the resistance opposite Dobrogea's old mountains, the course of the Danube turns abruptly to the east, thus maintaining its shedding into the Black Sea (Vlasceanu *et al.*, 2015).
As far as the hydrographical basin is concerned, it is asymmetric, being more developed on the left side; this characteristic is also observed in the morphological aspect of the riverbed, with the right bank being higher, with a general appearance of hilly plateau which rises locally by 200 m. The left bank presents itself as a wide plain. If we are talking about the Danube tributaries in this sector, they are bigger on the left, on the territory of Romania (Jiu, Olt, Arges) and smaller on the territory of Serbia and Bulgaria, although more in number (Timok, Ogosta, Iskar, Vit, Osam, Iantra, Lom). It includes the most beautiful and longest defile from Europe - the Iron Gates (144 km), a subsector with obvious asymmetry (Drobeta Turnu Severin - Calarasi, 566 km) (Murariu *et al.*, 2013).
A quite characteristic subsector is that of the valleys between Călăraşi and Braila, where the Danube spreads in several arms, encompassing among them the meadow itself called Balta Ialomiţei (or Borcea), bounded by the arms of Dunarea Veche and Borcea and Balta (Vâciu, Mănuşoaia, Cremenea, Pasca, Caila, Arapu), forming smaller islands in the west and Măcin Arm (Old Danube) in the east. In this subsector, the Danube collects smaller tributaries - Ialomita and Calmatui on the left, after which, in the last subsector, the Danube receives, as larger tributaries, Siret and Prut.
From Ceatal Izmail, there is the Deltaic sub-sector of the Danube, between Chilia (117 km), Tulcea (19 km) and Sfântu Gheorghe (109 km after the meander correction 77 km in the south) and which sums up 2540 km^2 (on the territory of Romania), and in the middle of the delta the Sulina arm, which after correction, is 63 km long. This continuously developing territorial geographic unit as a result of the action of the river through those 6473 m^3 / s of water and 58

[1] Corresponding author: alexandru.banescu@yahoo.com

million tonnes per year of alluvial on the one hand and the action of the waves on the shore on the other hand has constituted and constituted a thesaurus for the fauna and the folklore unique in Europe (Ivan et *al.*, 2012).

From the point of view of the water resource, the Danube River, which has an average stock at the entrance to the country of 174 billion cubic meters per year, could be the richest source of water. Its international character imposes certain limitations on the use of its waters and for this reason is considered only half of the average multiannual volume drained on the Danube in the Baziaş section, ie approx. 87 billion m^3. The ratio between minimum and maximum flows varies between 1/5 and 1/8. The water transport is an important branch being provided by the most important navigable waterway in Romania. The main river ports in the Romanian part of this sector are: Orsova, Drobeta-Turnu Severin, Calafat, Corabia, Turnu Magurele, Zimnicea, Giurgiu, Oltenita, Calarasi and Cernavoda. Fluvial-maritime ports - Galati, Braila, Tulcea. These are traditional harbours, situated at the intersection of the two types of waterways, sea and river. Two hydro technical facilities are in operation on the Romanian Danube sector: Iron Gates I and Iron Gates II, both for hydroelectric power generation and for ease of navigation (Gasparotti, *et al.*, 2012).

2. The Flow on the Danube

The average multi-annual flow rate of the Danube is not constant, depending on the length of the time period considered. Thus, in 1967, the average annual flow rate at the Orşova hydrometric station was 5420 m^3/s for a calculation interval of 122 years and 5390 m^3/s, if the calculation interval was 41 years (1921-1962). Further studies give different values for multiannual average flows. Thus, Table 1 and Table 2 show the multi-year average/maximum flow rates for different ranges (Banescu *et al.*, 2018).

Table 1
Multi-Annual Average Flows

Source: Report– Preliminary Flood Risk Assessment Danube Hydrographic Basin

Generally, in the course of one year, the minimum drain on the Danube is recorded at the beginning of spring, on classes of debit values and the lowest flow rates occur in the winters with very low temperatures, when influenced by the evolution of ice formations. Between 1965 and 2012, on the Danube there were recorded floods with maximum flows of more than 10,000 m^3/s, in 24 years maximum annual flash-floods that are on classes of debit valuess: maximum flows between 10000 m^3/s and 13000 m^3/s in 20 years; maximum flows between 13000 m^3/s and 15000 m^3/s in 3 years; maximum flows higher than 15,000 m^3/ s, in a year. Typically, the maximum flow rates on the Danube occur in the spring-summer period, the peaks occurring more frequently in April and May. However, there are some exceptions when flood waves occur either in December and January or late summer in August-September. As maximum flow rates, however, those that occur during the spring-summer period, which are actually considered as big waters on the Danube, stand out (Rusu *et al.*, 2014).

3. Arrangements to Ensure Navigation Conditions

The first engineering works on the Danube were initiated between 1834 and 1837 and consisted of river settlement works in order to improve the navigation conditions at the Danube exit in to the defile.

As for the works that took place on the Sulina arm, they consisted in the construction of two dams located at a distance of 180 m between them.
At the inauguration of the works (3 September 1861), the northern dike was 1412 m long and the southern dike 1212 m. The depth at the bar was 17 feet and a half (5.33 m), that is, the double depth at the beginning of the works with 2 feet longer than the one designed. This first success resulted in the transformation of the works initially conceived as temporary works in permanent works. There followed (1858-1902) works for the rectification of the Sulina branch by cutting the meanders, deepening and calibrating its cross section.
The route was shortened by 21.2 km (from 83.8 km to 62.6 km). Correction of the route did not raise special problems except in terms of landfill volumes (about 25 million m3). Instead, the consequences were completely unforeseen. The liquid flows transported on the Sulina branch, due to the shortening, doubled, the contribution of this arm increasing from 7% to 16% of the total flow of the Danube.
It is obvious that the same proportions also increased the solid flows, which led to difficulties in maintaining the depths at the mouth of the spill. It is interesting to note that due to the favourable situation of the depths, the dredging works on the Sulina arm and its mouth began only in 1894 (Gasparotti *et al.*,2016).
Difficulties are not delayed due to the growth of the south bank and the sanding of the Mosura bay due to the considerable contribution of alluviums of the Starâi-Stambul arm from the secondary delta of Chilia, the natural depths at the bar have decreased in recent years in a worrying proportion.
As a result, the volumes of works increase considerably.
The length of the dykes reached almost 8 km in 1973 and the volume dragged almost 50 million cubic meters. In order to improve navigation conditions on the Romanian Danube sector, after 1900 many works were carried out, but more local and smaller (Iticescu *et al.*,2013).
The hydrological regime, fuelled by rain and snow, made it possible to navigate the Danube throughout the year, and the environmental conditions and food resources offered facilitated the development of human settlements. Many river ports were created, true gates to the European world, where a large number of travellers, tourists and large quantities of goods circulate.
Among the well-known Romanian ports are Orsova, Turnu Severin, Giurgiu, Turnu Magurele, and Oltenita. The ports of Braila, Galati, Tulcea and Sulina are classified as river - sea ports. There are four river ports on the Danube-Black Sea and White-Gate - Midia-Năvodari waterways (Ivan *et al.*, 2009).

4. Exploitation of Mineral Aggregates on the Danube

The extraction activity of the mineral aggregates on the Danube, the left bank is made for subsequent sorting and use in various construction activities. This activity, even if controlled, can induce changes in the flow regime such as changes in flow rates, changes in the transport regime of the Danube alluviums which may lead to the appearance of sand beams at different times of the year, thus making difficult to navigate the ships. At low levels of the Danube, the ballast extraction - Figure 1 has somewhat influenced the occurrence of sand islands in the area of exploitation.
The sand formations are transported by the Danube and are deposited in favourable areas along the river. This may make the transport regime on the Danube uncomfortable, especially in the period when the river's share is low (Vlasceanu *et al.*, 2015).

Fig. 1.
The Exploitation Of Mineral Aggregates Using the Digging Machine

The study was conducted over a period of 2 years, starting in the autumn of 2016 and ending in the summer of 2017. During this period, 2 measurements were made on the Danube between 521 km and 524 km. In the respective perimeter, exoplanets took place only in 2016. The study consisted in the performance of topo-hydrographic

measurements on the Danube, namely: topobatimetric measurements, flow and speed measurements. The results of these measurements can be seen in Figure 3, Figure 4, Figure 7, and Figure 8.
The measurements on the Danube were made using a multi-beam multi-beam sonar, equipped with a high-performance GPS system that records real-time water depth, depth water velocity, the flow on section and position x and y. The data processing was done using specialized GIS (Geographic Information System) programs. Various cartographic materials (topographic maps, orthophotoplanes) have been used to generate 3D models. These materials were processed in GIS software (ArcMap and Global Mapper) to select the study area and bring it to the suitable reference system (Stereo 70) with the Black Sea 75 reference system (Arseni *et al.*, 2017) (Basarab et al., 2006).
The anthropic impact of the analysed area after the implementation period of the exploitation activity is manifested by the appearance of a sand land with a significant surface, reducing the surface of the water glistening on the Danube. This may affect the flow regime and, implicitly, ship transport on that area (Rusu *et al.*,2014).
The objectives of this study are to present the effects of mineral aggregate extraction activities on the Danube km 521 - km 524 left bank – Figure 2, in order to create an image of the impact that sand land could have on the movement of vessels on the river, both for ships that run from downstream to upstream and for those running from the opposite direction.

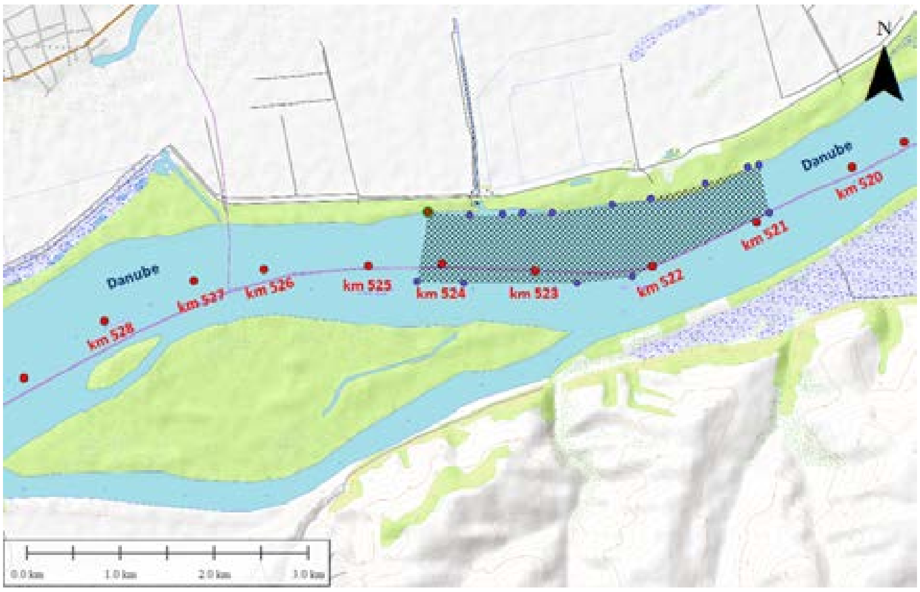

Fig. 2.
Perimeter of the Analyzed Area - Danube km 521-km 524 Left Bank

Measurements were made by over lighting with the multi-beam sonar in the analysed area following a classical procedure, namely data collection on the longitudinal axis (longitudinal profiles along the proposed length of km 521-km 524) and data collection across the cross-section (cross sectional profiles from 50 to 50 of meters).
The GIS methods used have contributed to the generation of digital maps where we can easily observe the 3D model of the Danube bed in the perimeter under consideration and the areas where the excavations were made. The breakdown of these results is presented in Figure 3 and Figure 7. Following the data processing, a cross section (section 1) was generated in the first phase on the model created in 2016 and in the second phase on the model created in 2017 in the same place respecting the same coordinates - Figure 4 and Figure 8.

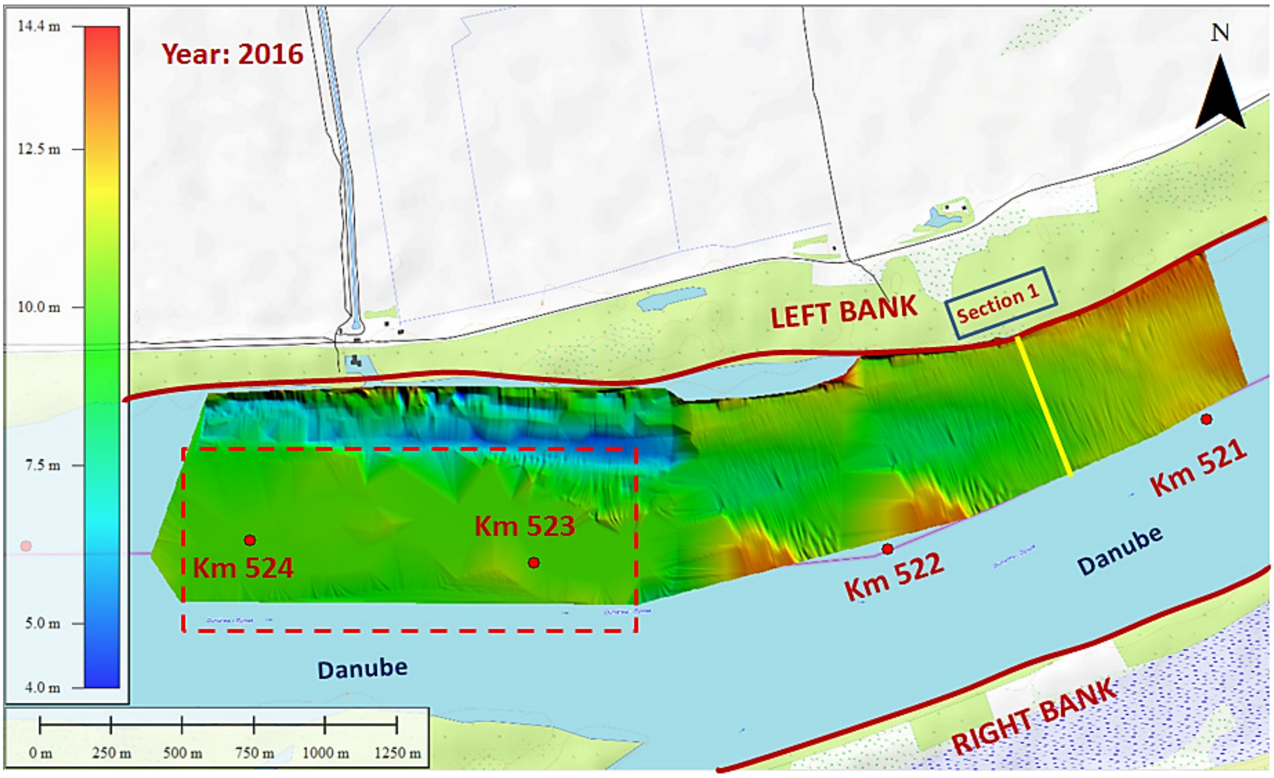

Fig. 3.
The 3D Model Made Using GIS Methods - Measurements in 2016

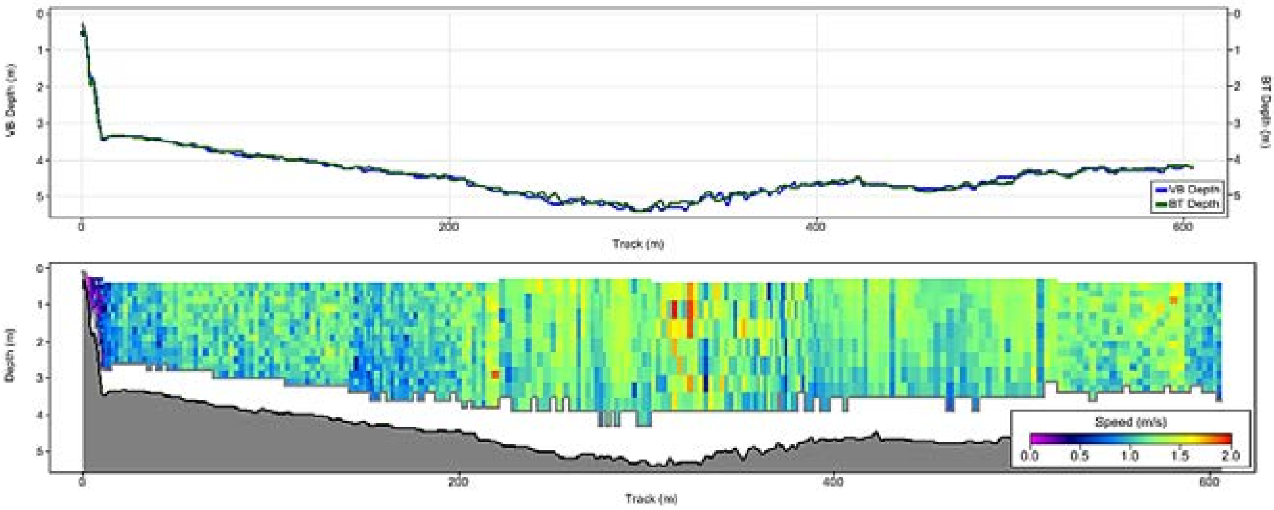

Fig. 4.
Cross-Section on 3D Model (Year 2016)

The mid-section method involves making a series of velocity and depth measurements at a specific number of locations (more commonly known as stations, panels or verticals) across a river cross-section. At each station, the depth and mean velocity profile are measured. The depth is computed using either the 4-velocity beams, the low-frequency vertical beam, or manu-ally measured (using a rod or other device) and entered into the software. The mean velocity profile for each station is computed from data from all valid cells above the riverbed (Figure 5). The width of a single station is determined to be the sum of half the distance to the previous station and half the distance to the following station. This method assumes that the velocity profile at each station represents the mean velocity for the entire rectangular station area.

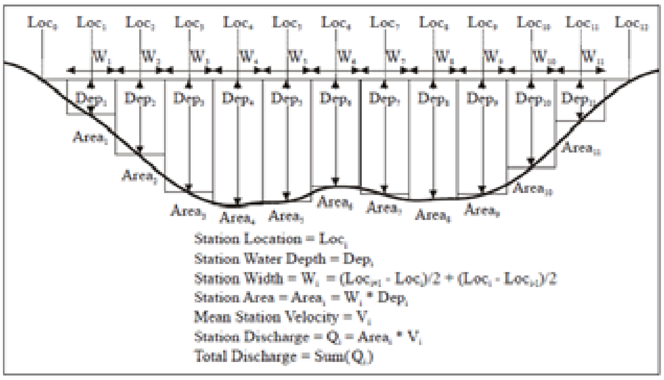

Fig. 5.
Cross Section Details

Each station is measured for a significant time to remove any environmental and temporal variation in the water velocities. Typically within the operation, the recommended duration of measure-mint for a single station is 40 seconds. However, in particularly turbulent waters, extremely low-velocities, or in areas or rapidly changing water-level, a longer period may be required.
The basic procedure for making a discharge measurement using the Stationary- Measurement system is as follows:

1). Setting up the Location:
- a measurement section is selected based on the criteria
- a graduated tag line is strung across the river. In an ideal measurement site, the flow should be perpendicular to the tag line at all points with no flow reversals or obstructions
- the spacing of the stations along the tagline is se-elected so as to provide about 20-30 stations. Each of these stations should also be positioned so that no station is expected to yield more than 10 % of the to-tall discharge. Ideally, no station should have more than 5% of the total discharge. This generally means that the stations are not equally spaced but are instead spaced closely together in deeper and high velocity areas and further apart in shallower and slower flowing are-as.
- the magnetic-north heading (azimuth) of the tagline is measured. This is the compass orientation of the tagline in the direction of the right river bank. Setting the tagline azimuth is important because it allows the device to rotate freely around the sample location and still measure the correct mean-station velocity by using its internal compass to resolve the true direction of velocity and then calculate the normal velocity to the tagline.

2). Setting up the Software:
- Connects to the software
- The information is entered into the system. This information includes the site name, number, location, starting bank, gauge heights, azimuth, velocity-reference meth-od, depth reference method

3). Making the measurements:
It's starts at a margin (the start bank), recording the starting-edge location, water depth and gauge heights.
- The procedure is forwarded to the first station and enters the station location, transducer depth, and gauge heights. If ice is present, the values for the ice thick-ness, depth of water and slush thickness should also be entered
- The positioning is done with the transducers submerged and the system as vertical as possible. Ideally the system will be mounted to a platform, vessel, or mounting structure.
- Thus, data collection is performed and is measured the 3D current velocities and bottom depth throughout the water column
- Only the component of water velocity perpendicular to the transect line (or azimuth) is used to ensure proper discharge calculations, regardless of the flow direction. This nor-mal component of the velocity is known as the ―Normal Velocity

Basically, the total discharge is the amount of water flow (or net flux) through a section and is computed from the mean water velocity and the cross-sectional area of the measurement section. A single moving boat measurement of discharge can be broken into three key components: the Start Edge, the Transect and the End Edge. These components are shown in Figure 6 below:

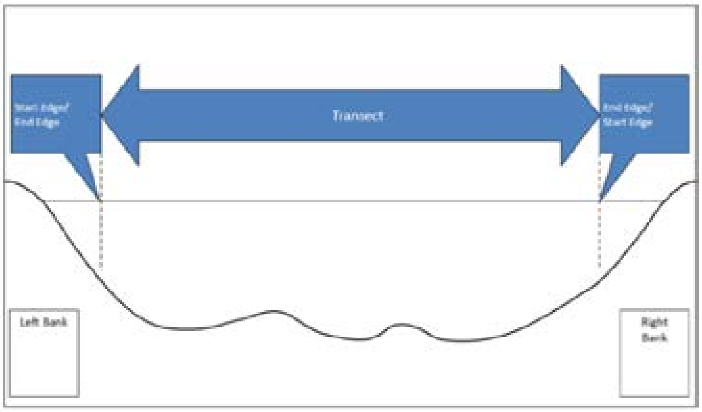

Fig. 6.
Steps for Making a Measurement

Each profile displays dates about the length of the section (track in meters from 0 to 600 meters), depth of water (depth in meters from 0 to 5 meters), water speed on depth (m/s at speeds of 0 m/s - 2 m/s). If we compare the two profiles we can observe that the appearance of sand in the studied perimeter does not greatly influence the speed of the water on the depths, the values of 2017 are slightly higher than those of 2016. Danube level compared to the Black Sea reference system 75 (rMN75) was approximately the same at the time the measurements were made. The difference between the two odds is only 60 cm. In the autumn of 2016, the Danube's share of the measurements was 14.45 m rMN75, and in the summer of 2017 the Danube's share reached 15.05 m rMN75.

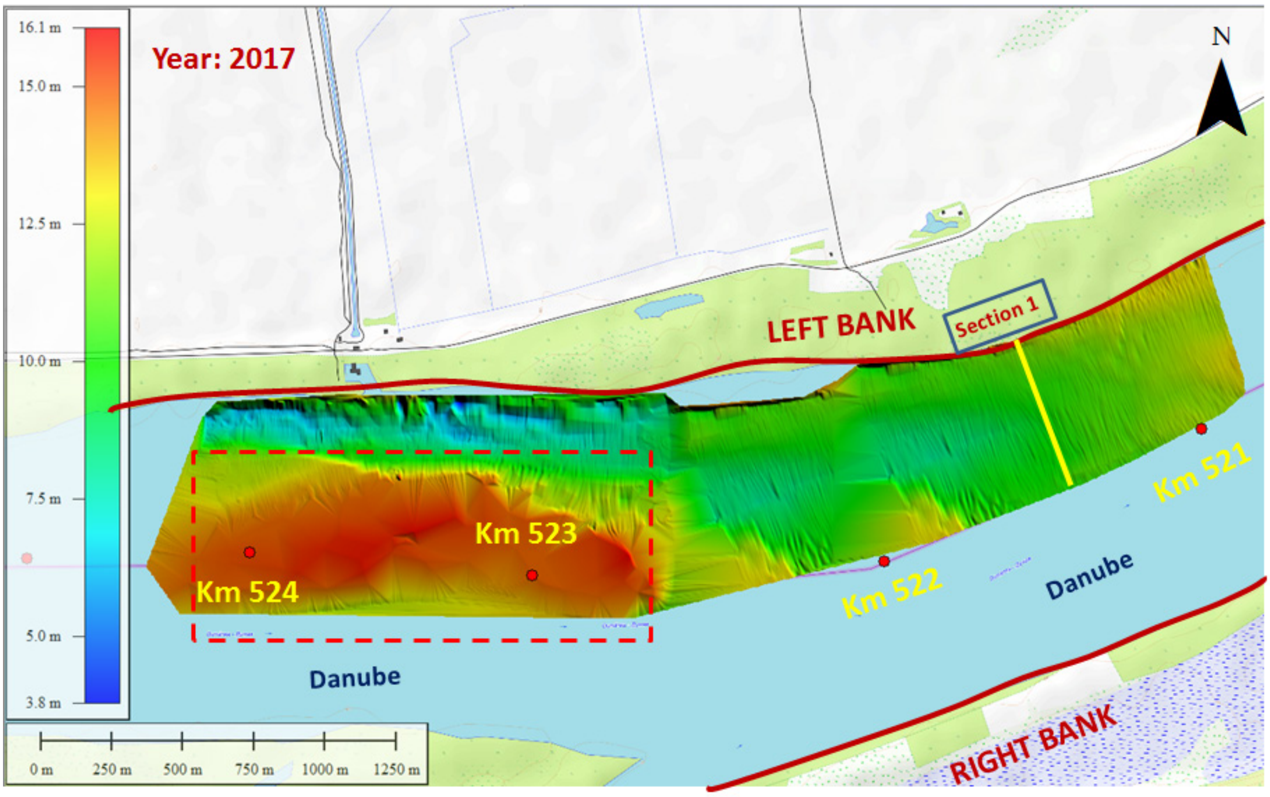

Fig. 7.
The 3D Model Made Using GIS Methods - Measurements in 2017

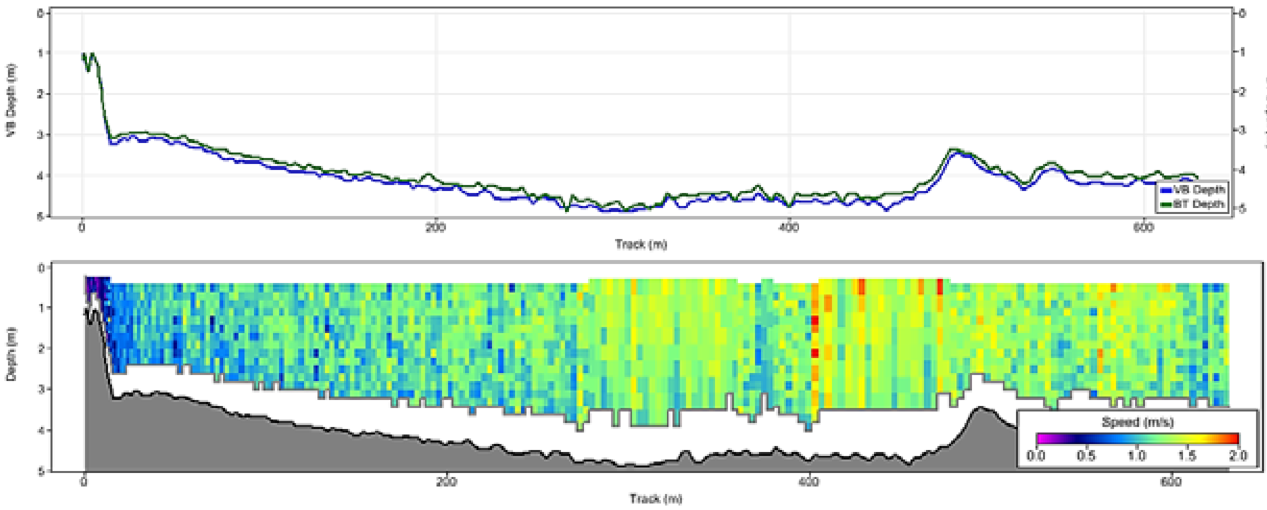

Fig. 8.
Cross-Section on 3D Model (Year 2017)

The water level regime is of particular interest to navigation, because knowing the water levels recorded on the river can determine depths on the navigable channel, the thresholds, the navigable axis of the navigable system and the navigable gauge (Rusu, 2010).
Water levels across different Danube sectors vary depending on hydro meteorological conditions, surface slope, bottom relief, ice and wind regime, regularization works, aggregate exploitation works, etc.
Sand lands on the Danube are formed on the basis of solid particles crossing a section of the river during a time unit called alluvial flow and expressed in units of weight per second. The alluvium flow is composed of suspended particles and pushed particles on the bottom of the bed. The bottom particles are continuously affected by the current speed that pulls them from the bottom of the bed to push them (Rusu *et al.*, 2014).
The particles on the bottom of the bed move on the bottom of the bed or remain suspended in the water. On the upper course of the Danube, alluviums are generally made of coarse sand. As it approaches the confluence, the suspended particles become, in large part, bottom alluviums (Gasparotti *et al.*, 2013).
The presence of sand lands on the Danube is considered in navigation, zone of difficulty. Areas of difficulty are portions of the sailing line where, due to the reduction in water scarcity or due to particular hydrological conditions, navigation of vessels and, in particular, convoys cannot take place under normal conditions, requiring specific measures and restrictions for the safety of navigation through these sectors (Vlasceanu *et al.*, 2015) (Murariu *et al.,* 2009).

5. Conclusions

The works carried out on the exploitation of natural aggregates in river beds can induce states of imbalances, so they must be carefully monitored, analysed, and approved by competent administrations in this area.
It should be underlined that different islands of different sizes are formed along the Danube at different times of the year, which makes them very difficult for the river navigation. Their shape and dimensions are constantly changing under the influence of the water level changes, water flow rates and aggregate exploitations.
From this perspective, the present paper follows how these aggregate exploits influence the appearance of the sand islands along the Danube. The study is based on "in situ" measurements carried out in two different time periods, ie in the autumn of 2016 and continuing later in the following summer, 2017. The measurements were based on a multi-beam mille beam sonar that recorded over time real water depth, water flow rate and flow, and the position of the measured points x and y.
The results were obtained by processing data using GIS methods and representing a comprehensive picture of the analysed sector in different viewing modes.
The GIS methods used have contributed to the generation of digital maps, where we can easily see the 3D model of the Danube bed in the perimeter of exploitation. Various cartographic materials (topographic maps and orthophotomaps) in general were used to create 3D models to select the area of study and to bring it to the appropriate reference system.
All these aspects are of particular interest for safer navigation on the Danube for both large ships and small craft.

Acknowledgement

This work was carried out in the framework of the project proposal ACCWA, supported by the Romanian Executive Agency for Higher Education, Research, Development and Innovation Funding – UEFSCDI, grant number PN-III-P4-IDPCE-2016-0028.

QUANTIFYING THE EFFECT OF THE SHIP VIBRATION ON CREW FOR THE INLAND NAVIGATION- CASE STUDY A CARGO NAVIGATING IN THE LOWER DANUBE SECTOR

Laurentiu Picu[1], Eugen Rusu[2]
[1, 2]Dunarea de Jos University of Galati, 47, Domneasca Str., Romania

Abstract: This paper studies how the vibrations of a cargo ship are transmitted to crew members. The measurements were made on the navigating bridge, on the main deck and in the engine room during various maneuvers: start-up, shore, idling with generator engine, mooring manoeuver. The accelerations transmitted to the body were measured and were calculated: Partial VDV (Vibration Dose Value), Partial exposure A(8), Time to reach EAV (VDV option), Time to reach EAV(A(8) option only) (Exposure Action Value), Total VDV, Total exposure A(8). In the engine room were measured accelerations of up to 6.743m/s^2, while the calculated VDV is extremely high: 56.3m/s$^{1.75}$, time to reach EAV (Exposure Limit Value) is 2-3 min and time to reach ELV is 14-21 min. In conclusion, the working conditions of crew members must be improved.

Keywords: Danube River, navigation, vibrations, human response, crew.

1. Introduction

Vibrations transmitted by equipment to the human body during work hours are dangerous to the health of the crew. There are a lot of studies on the negative effects of vibrations on people working in such an environment: industry (vehicles, cranes); constructions (excavating machines, trailers, cranes, bulldozers, crawlers); transports (buses, trucks, cars, planes, ships, helicopters, metros, railway engines); agriculture (tractors, dirt mover) (Picu, 2012, 2013).

"There are two types of occupational vibrations: of one segment and of the whole-body. The vibrations from the steering wheel are transmitted through the hand and arm and lead to some specific disorders like Raynaud Syndrome. The whole-body vibration is transmitted through the support surfaces of the body: legs, for the vertical position case, or buttocks and back, for the seated position." (Picu and Nastac, 2011)

In respect with this there are a lot of standards that regulate work in a vibrant environment (EN 1032; ISO 2631-1; ISO 2631-4; ISO 5349). An activity with special characteristics is that of sailors who spend most of their time on the ship.

The sailors' body is exposed to vibrations during the entire journey. It was proved that vibrations lead to disorders of the muscular and skeletal system, of the hand as well as of the arm, neck and back (Picu and Nastac, 2011; Picu and Rusu, 2017).

For this reason, Directive 2002/44 / EC clearly states: "In the case of sea and air transport, given the current state of the art it is not possible to comply in all circumstances with the exposure limit values for whole-body vibration; provision should therefore be made for duly justified exemptions in some cases" (DIRECTIVE 2002/44/EC).

Mariners are exposed to ship movements due to waves that can cause "seasickness". Vibrations generated by engines and other sources of excitation, can cause increased discomfort. The perception and the response to these disturbing factors as well as the influence on work performance were investigated (Gasparotti and Rusu, 2012; Ivan, Gasparotti and Rusu, 2012; Rusu, Butunoiu and Rusu, 2014). This influences both their physical and mental abilities (Bittner, 1985).

The way in which vibrations are transmitted through the structure of the ship, whether due to waves or equipment, should be taken into account when designing the vessel (Carlton and Vlasic, 2005; IFSTTAR, 2014).

The objective of this paper is to study the way a cargo ship transmits vibrations to the crew members. Vibration accelerations transmitted to the whole-body were measured on the navigating bridge, on the main deck and in the engine room.

2. Materials and Methods

In this paper the measurements of whole-body vibrations (WBV) were made on a cargo ship on the Danube, over a distance of 175 km (Picu, 2015; Picu and Nastac, 2010).

The atmospheric conditions were good (T = 16^{0}C, no wind, moderate waves). At the beginning of every test the each sailor was asked if he/she feels comfortable in the desired position; the measurement system was calibrated.

The vibrations were measured in normal working conditions, according to International Standard ISO 2631-1. The whole-body vibration, in different conditions, was measured on the 3 axes x, y and z from the centre of the human body.

The whole-body vibrations were measured using: 01dB NetdB Multichannel digital recorders and real-time analysers with 12 activated channels acquisition, triaxial whole-body accelerometer SEAT-pad (Seat Effective Acceleration Transmissibility), triaxial whole-body accelerometer PCB Piezotronics 356A16.

The accelerometer was fixed with clips, according to ISO 5349-2:2001. The axes were oriented in the directions specified in EN 1032:2003. The accelerations generated by vibrations were calculated using the weight factors set by ISO 2631. The calibration of the accelerometers was made with VE-10 Rion.

The data processing was made with dBFA Suite-Control Software for data acquisition and post-processing (http://www.acoustic-glossary.co.uk/vibration-dose.htm). The data acquired during the experiments were processed using the calculation given by ISO 2631-1:1997. The ISO 2631-1 parameters evaluated included:

[1] Corresponding author: laurentiupicu@yahoo.com

a) Root mean square average vibration (A_w) calculated at the floor, lumbar, cervical and forehead:

$$A_w = \left[\frac{1}{T}\int_0^T a_w^2(t)dt\right]^{1/2} \quad (m/s^2) \qquad (1)$$

b) Vibration dose value (VDV). This value is more sensitive to impulsive vibration and reflects the total, as opposed to average vibration:

$$VDV = \left[\frac{1}{T}\int_0^T [a_w(t)]^4 dt\right]^{1/4} \quad (m/s^{1.75}) \qquad (2)$$

c) The time period needed to reach the value of the exposure which triggers the action (EAV) and the limit exposure value (ELV):

$$T_{EAV_{A(8)}} = 8\left(\frac{0.5}{A_w}\right)^2 \quad (h) \qquad 3)$$

$$T_{ELV_{A(8)}} = 8\left(\frac{1.15}{A_w}\right)^2 \quad (h) \qquad (4)$$

The measuring conditions on human were different: the start from the shore, running, idling with generator engine, mooring manoeuver. To determine the noise on ship, in different places of that, were made measurements with SOLO soundmeter: in wheelhouse, on the main deck and the engines room, on the navigating bridge and in the rest area.
As for the daily exposure value from which the action is triggered (8h/day) at European level, the following practices are met: 4.5 m/s^2 - 4h/day of exposure; 6 m/s^2 - 2h/day of exposure; 9 m/s^2 - 1h/day of exposure and 12 m/s^2 - 0.5h/day of exposure.

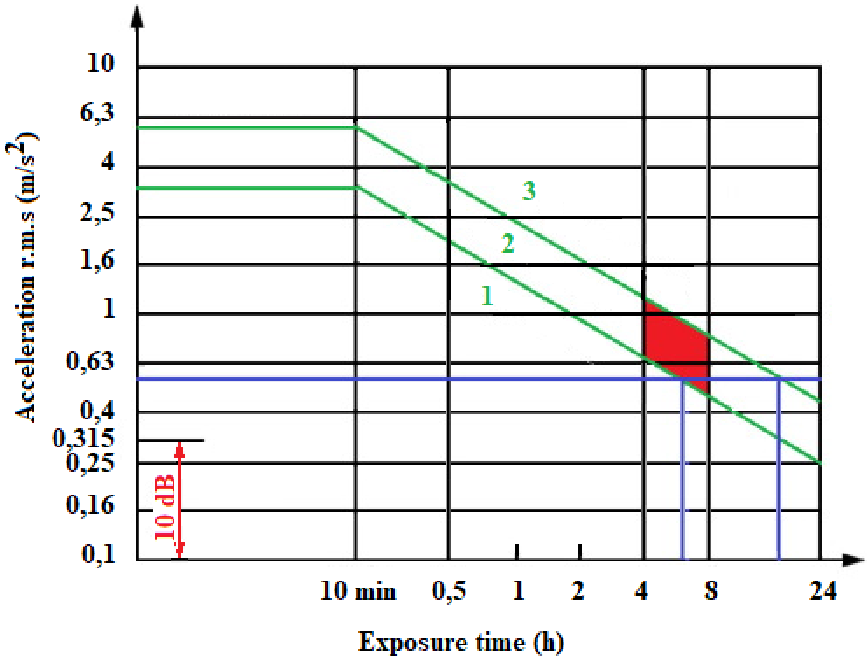

Fig. 1.
Areas of Attention in Health Warnings (ISO 2631-1)(1) - Risk-Free Area; (2) - Area With Risk Potential; (3) - Risk Area, ( ) - Attention Area

Whole-body vibrations values were calculated over the whole route, as well as by individual segment. A GPS was also used to collect and integrate the data and to identify the location and the velocity associated with the WBV exposures. Each experiment was repeated 5 times in order to obtain an accurate averaging of the experimental data.
Five male subjects were chosen for this experiment with different body weights, ages and work experience (Table 1).

Table 1
Information About Subjects

Subject	Weight (kg)	Age (years)	Smoker	More than 2 glasses of wine/day	Seniority (years)
1	≤70	≤50	Yes	Yes	21
2	71–93	≥50	Yes	Yes	38
3	71–93	≤50	Yes	Yes	41
4	≥94	≥50	-	-	35
5	≥94	≥50	Yes	-	33

3. Calculations and Results

Tables 2 present the mean values of accelerations measured on the navigating bridge, on the main deck and in the engines room (the accelerometer is fixed on the floor).

Tables 3÷5 present the calculated values for: Partial VDV, Partial exposure A(8), Time to reach EAV (VDV option), Time to reach EAV (A(8) option), Time to reach ELV (A(8) option only), Total VDV, Total exposure A(8). The calculation was done with: Vibration exposure calculator - Telenet.

4. Discussions and Conclusions

a) Parallel between the root mean square average vibrations, measured at the floor, in the 3 cases**:** on the navigation bridge, on the main deck and in the engine room.
Figure 2 shows that all acceleration values are located above the EAV limit ($0.5m/s^2$) for people on the navigation bridge and on the main deck (in all cases: the start-up, shore, idling with generator engine, mooring manoeuver). There are a few situations for which the acceleration values are below the ELV limit ($1.1m/s^2$). The situation is changing dramatically for people in the engine room: accelerations of up to $6.743m/s^2$ were measured here.

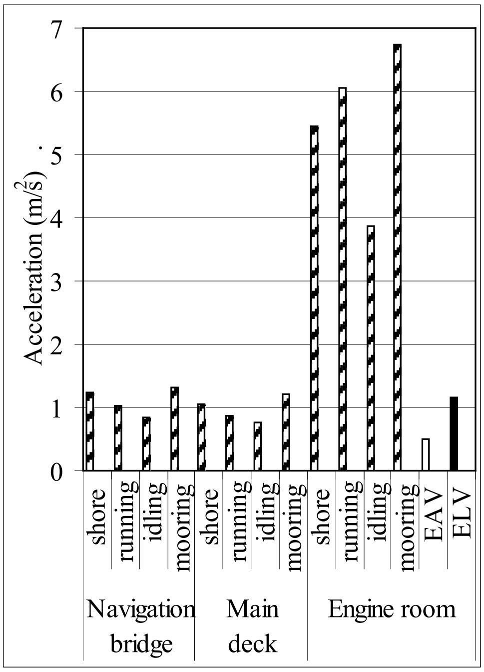

Fig. 2.
Average acceleration measured with accelerometer on the floor of the navigation bridge, the main deck and in the engine room; (□) –EAV limit; (■) –ELV limit

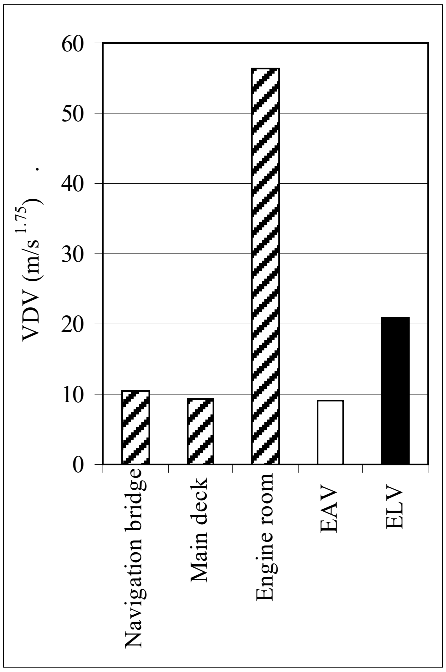

Fig. 3.
Average VDV calculated on the navigation bridge, on the main deck and in the engine room (□) –EAV limit; (■) –ELV limit

b) Parallel between vibration dose value, calculated at the floor, in the 3 cases: on navigation bridge, on main deck and on engine room
Figure 3 shows that all calculated values are below the EAV limit ($9.1m/s^{1.75}$) for people on the navigation bridge, the main deck and the engine room (where an extremely high value was reached: $56.3m/s^{1.75}$).
c) Parallel between time periods to reach the exposure value which triggers the action and time periods to reach the limit exposure value
Another value interesting value for studying vibrations which are transmitted to the crew is the time period necessarily to reach the exposure value which triggers the action. Figures 4÷6 clearly show that these values are particularly low for the staff on the navigation bridge: T_{EAV}=1.14h and T_{ELV}=6.05h and on main deck: T_{EAV}=1.35h and T_{ELV}=7.15h for mooring. For the engine room workers the values are dangerously small for all maneuvers: T_{EAV}=0.04-0,06h (2-3 min) and T_{ELV}=0.23-0,35h (14-21 min).

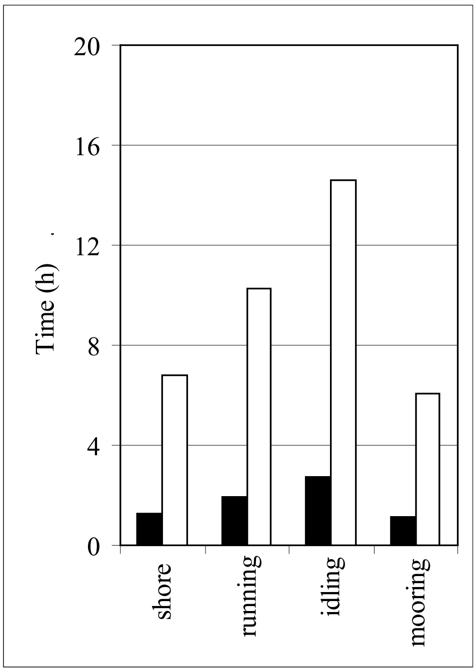

Fig. 4.
Parallel between T_{EAV} (■) and T_{ELV} (□): Navigation Bridge

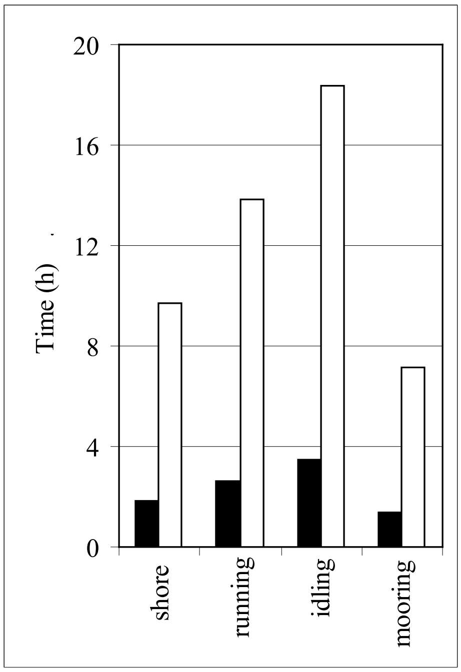

Fig. 5.
Parallel between T_{EAV} (■) and T_{ELV} (□): Main Deck

In conclusion, this paper analyses the vibrations to which the crew of a cargo ship is exposed while travelling on the Danube. It can be seen that all values characterizing the vibrations transmitted by the ship to the hole body of the sailors (A_w, VDV, T_{EAV}, T_{ELV}) lead to the same conclusion: it is necessary to improve working conditions. Of all the areas on the ship, the most dangerous is the engine room; the legal norms are exceeded a few dozen times. The 8h work schedule or even more, in such conditions is extremely harmful to people's health.
It is imperative to improve the working conditions of crew members. All solutions that can be applied according to the specificity of each ship (gloves, boots, supports, antivibration mats) will be used. The antivibration supports will be replaced if damaged and will be installed where they are missing. Where possible, soundproofed and antivibration rooms will be built for the mechanics to use while supervising the engine room and when they are not working on a repair. The remarks on the high level of discomfort caused by vibration-producing equipment will have to be taken into account as early as ship design and material selection.

Abstract: The transportation sector is directly related to almost any activity in Europe. Transportation and mobility play a fundamental role in today's world. The European Commission's aim is to promote the mobility that is efficient, safe, secure and environmentally friendly, serving the needs of citizens and businesses. At the European Union level, the transportation sector aims to promote efficiency on the European single market and to sustain connectivity on a global scale. To achieve these goals, EU must implement actions of decarbonization, digitalization, investment, people's benefits, innovation and global leadership, which are sustainability components Transportation has a major impact on Europe's social, economic and environmental development. That is why this is considered a strategic sector of the EU economy. At the local and regional levels, transportation contributes to economic growth, creating new jobs, helping SME's global competitiveness and trade and helping people and goods to move across Europe. From this perspective, the creation of a waterway which links the Baltic and the Black Seas fits perfectly into the objectives of the European Union. From this perspective, in this paper we analyze the sustainability of this project idea, taking account of the economic, financial, operational, social and environmental considerations. The analysis of these factors presents a clear and concrete situation of the decisions to be taken by the policymakers. This paper examines the feasibility of establishing a navigable route along the Vistula-Prut rivers waterway, connecting Baltic and Black Seas through the Danube River. The new transport waterway will became an alternative with the competing modes of rail and road. The waterway service offers an alternative from energy and carbon to roads and railway freight. The inland waterway transportation (IWT) could have a high potential in the Eastern Europe countries, with an inland waterway which will connects the Black and Baltic Seas under some conditions (e.g. improving infrastructure, increasing the size of vessels, increase cooperation between authorities). Inland transportation will gain a competitive advantage against other modes of transportation, particularly in the junction area with roads and seaports handling facilities.

Keywords: inland navigation; challenge; Black Sea, Baltic Sea, sustainability.

1. Introduction

The transportation sector is directly related to almost any activity in Europe. Transportation and mobility play a fundamental role in today's world. The European Commission's aim is to promote the mobility that is efficient, safe, secure and environmentally friendly, serving the needs of citizens and businesses.

At the European Union level, the transportation sector aims to promote efficiency on the European single market and to sustain connectivity on a global scale. To achieve these goals, EU must implement actions of decarbonization, digitalization, investment, people's benefits, innovation and global leadership, which are sustainability components represented in Figure 1.

This paper examines the feasibility of establishing a navigable route along the Vistula-Pruth rivers waterway, connecting Baltic and Black Seas through the Danube River. The new transport waterway will became an alternative with the competing modes of rail and road. The waterway service offers an alternative from energy and carbon to roads and railway freight.

The inland waterway transportation (IWT) could have a high potential in the Eastern Europe countries, with an inland waterway which will connects the Black and Baltic Seas under some conditions (e.g. improving infrastructure, increasing the size of vessels, increase cooperation between authorities). Inland transportation will gain a competitive advantage against other modes of transportation, particularly in the junction area with roads and seaports handling facilities.

Creating an inland waterway on the Prut River to connect the Baltic Sea and the Black Sea is not a new idea. Since 1926, the state authorities from Romania and Poland made diplomatic efforts to open a new waterway connecting the Prut, Dniester, San and Vistula rivers. Recently according to European strategies, which aim to develop a North-South transport corridor, the member states and their partners have the possibility to establish an integrated approach to economic and social opportunities.

The Black Sea is today a complex economic area undergoing development. From a strategic point of view, the Black Sea is located between Europe and Asia, being connected with the Mediterranean Sea. The economic activities are diverse, besides the transportation and tourism sector, the energy sectors, the exploitation of the natural deposits and the agricultural sector are growing.

The Baltic Sea is a developed economic space, with the riparian countries making efforts to systemize and streamline the cross-border cooperation methodologies. From this perspective, the European Union's strategy is to connect the Baltic Sea with other regions of Europe through a waterway system.

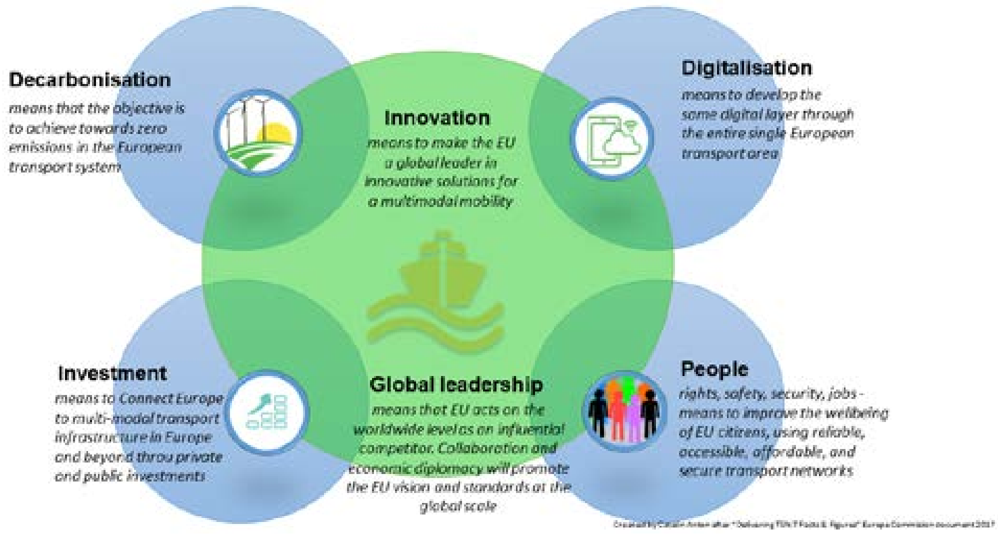

Fig. 1.
Actions to implement the EU transportation policies

Furthermore, the project to create a navigable channel between the Baltic Sea and the Black Sea is in line with the North-South European transportation corridor and it will bring to the same table Romania, Moldova, Ukraine and Poland, countries that will have to work together to complete this ambitious project. Navigation on the new waterway will begin at Gdansk in Poland, will continue on the river Vistula, will go on the San River, which will connect with the Dniester river and will continue on the Prut River, going to the Danube, near the city of Galati (Romania). From Galati it can be reached the Black Sea by two ways, the Sulina branch or the Danube-Black Sea canal having the final port of Constanta.
The Gdansk-Galati inland waterway would have a length of 1,900 km, of which only 72 km would involve excavated channel areas to make connections between the rivers the Vistula - San - Dniester – Prut. (Fig. 2) The distance between the Baltic Sea and Black Sea will be reduced from 7911 km (4272 nm) to 2068 km (1117 nm). The Prut River is the eastern border of the European Union, with a length of 716 km. The Prut River basin has an area of 28,396 square km, out of which 10,990 square km in Romania. The sectors on which the course should be modernized are the upper sector - from the source to the exit of the mountains, the Cernăuţi area, the Cernăuţi district to Ungheni and the Lower Prut, from Ungheni to the Danube, to Galati.
Aside from the economic and political benefits of the project, which more than justify the complex development of the Prut River, the current context poses an unique historic opportunity which requires consideration and acknowledgment.

2. Methodology

The EU Transportation Strategy defines sustainability in transportation systems as having economic, financial, operational, environmental and social dimensions. When we discuss about the IWT industry in Europe, these dimensions can be interpreted as components:

Economic sustainability. This involve the management of all resources of economic interest, which is necessary to meet the needs, in a manner that provides lasting positive economic value to society as a whole. With regard to IWT, the management of waterways (inc. their infrastructure) and riverboats towards securing adequate and reliable operations without compromising the needs of other water users.
Financial sustainability. The transportation sector must have access reliable and sufficient funds for the construction, operations and maintenance necessary for the availability of the offered services. Infrastructure owners and operators as well as service providers meet their financial needs through a multitude of sources ranging from public and/or private funds to revenue from end users.
Operational sustainability: The capability in terms of management, technical and technological issues to construct IWT infrastructure, and to operate and to maintain an increasingly busy and sophisticated inland waterway transport system more efficiently, safely and reliably.
Environmental sustainability: The inland waterway transport industry should meet ever-increasing political and public expectations of environmental high standards, including the energy efficiency and low carbon generation, as well as more stringent environmental regulations;
Social sustainability: This component ensures that the inland waterway transport industry is as a good partner of riparian communities that caters for the livelihoods of all affected by its presence.
These five dimensions are interdependent. If the inland waterway transport policy does not touch any of these components it may have an adverse impact on the others. For example, the industry will not be able to afford the adequate environmental standards if it is not financially sustainable. Similarly, if it is not environmentally sustainable, then it will not be able to meet its social sustainability commitment. Inland waterway transport policies need to address all the components of sustainability.
In order to have a tool for components evaluation in terms of sustainability, we have identified a number of 14 results areas (Figures 3, 4, 5 and 6) and 30 monitoring indicators. These indicators which belong to the sustainability components need to be scored on a scale from -3 to 3 (see scoring scale below – Figure 7).

ECONOMICS and FINANCIAL

1	INDICATOR	DESCRIPTION	SCORING RANGES								INDICATOR SCORE
The ability of the IWT industry to offer, maintain and continuously improve competitive transport services to freight customers in accordance with market needs and in a way that is financially viable.	Increase and diversify IWT traffic levels	Please indicate on a scale from -3 to 3 and clarify with examples	No, strong negative effects	No, considerable negative effects	No, weak negative effects	No changes	Yes, weak positive effects	Yes, considerable positive effects	Yes, strong positive effects	No Data	
			-3	-2	-1	0	1	2	3	X	
				-2							
	Maintain or increase modal share carried by IWT	Please indicate on a scale from -3 to 3 and clarify with examples	No, strong negative effects	No, considerable negative effects	No, weak negative effects	No changes	Yes, weak positive effects	Yes, considerable positive effects	Yes, strong positive effects	No Data	
			-3	-2	-1	0	1	2	3	X

3. Results

The present work will describe next the challenge of a possible future role of the inland navigation between the Baltic Sea and the Black Sea. The goal is to present a sustainability analysis with reference to the economic & financial, operational, environmental and social components. Taking into account the EU transport policy objectives the present study will summarize the main issues which have to be analyzed towards the long term sustainability of IWT. The results will be divided into those concerned with the **navigation infrastructure** (i.e. channels, locks, ship-lifts, navigation aids etc) – Figure 8 – to the **ports** (Figure 9), and to the **transport services (barging) industry** (Figure 10).

Economic and financial sustainability will be treated together, through their close interdependence with the operational, environment and social sustainability.

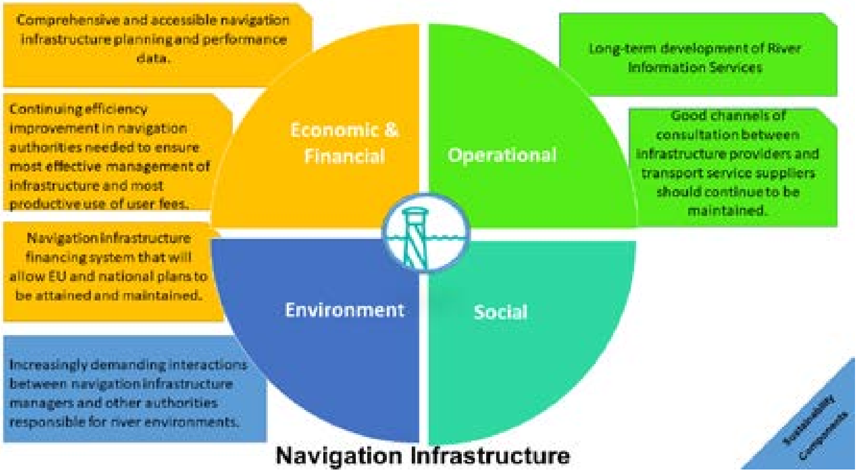

Fig. 8.
Sustainability components – Navigation Infrastructure

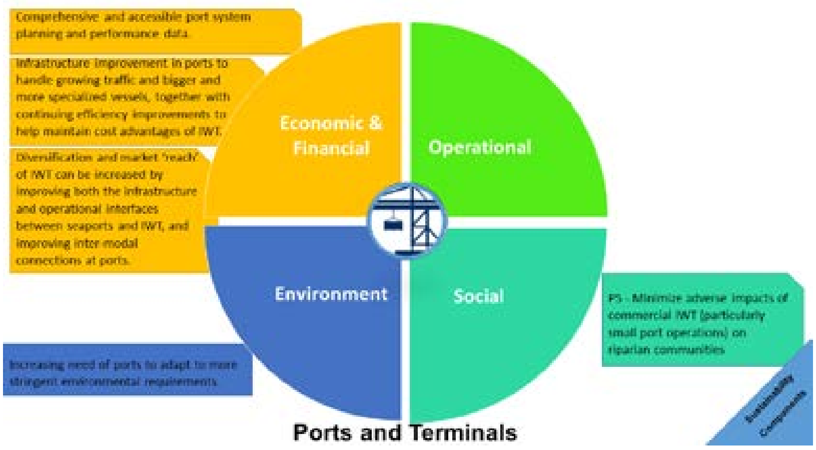

Fig. 9.
Sustainability components – Port and Terminals

Fig. 10.
Sustainability components – Barge Transport Industry

In this next stage, there is summarized the proposed monitoring framework for the project sustainability. Detailed observations are given on the right part of the figures below. As noted, the framework is indicative rather than definitive, and it can be adapted by every involved country to include or exclude particular result areas, for the figure of Economic & Financial (Figure 11), Operational (Figure 12) or Environmental and Social (Figure 13) or to modify the performance indicators to be monitored within each result area. It can also be implemented in stages over time, depending on the development of the information systems.

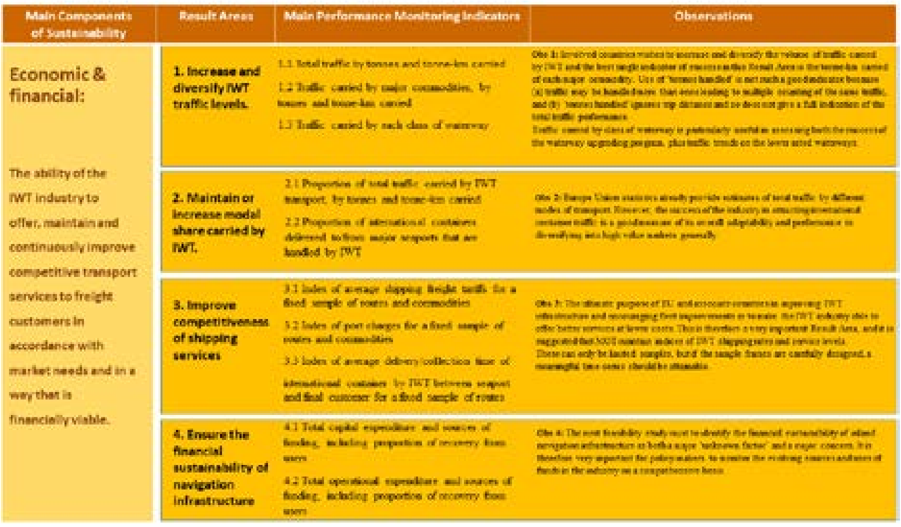

Fig. 11.
Sustainability of the IWT Industry - High-level Results Framework (Economic & Financial)

Fig. 12.
Sustainability of the IWT Industry - High-level Results Framework (Operational)

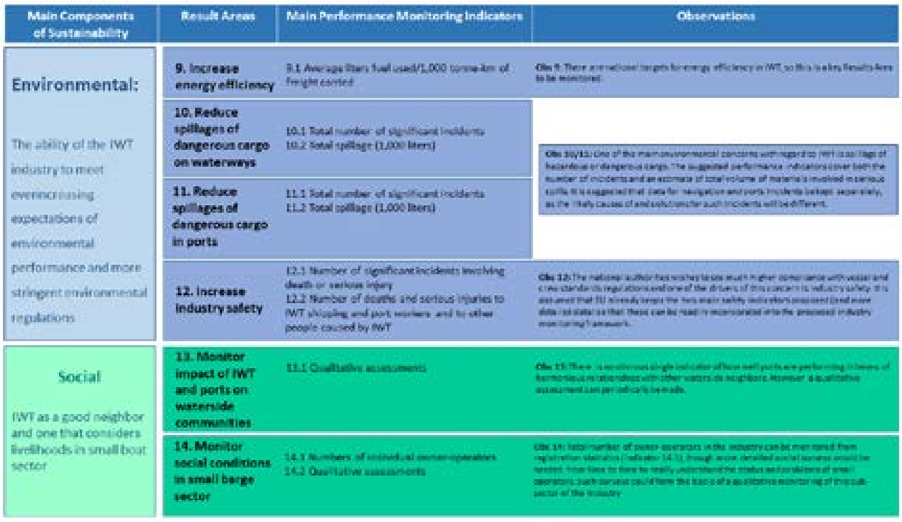

Fig. 13.
Sustainability of the IWT Industry - High-level Results Framework (Environmental & Social)

4. Discussions

In the European Union, there are fewer documents that look comprehensively across all transport modes, including IWT. Table 1 shows estimates the marginal costs of construction and maintenance of infrastructure, of the safety, emissions and other environmental costs of the three main modes of inland freight transport in the EU.
The major EU study in terms of GHG emissions, estimated that CO2 emissions per tons/km in EU freight transport are 672 grams for airfreight, 86.3 grams for road freight (in 40 tons-trucks), 34.4 grams for inland waterways vessels, and 29.4 grams for railways.

Table 1
EU Estimates of External Costs of Transport (EUR/100 tons-km)

Mode of Transport Construction and	Maintenance Costs	Safety, Social and Environmental Costs	Total External Costs (Excluding Operating Costs)
Roads	0,51	1,94	2,45
Railways	1,86	0,43	2,29
IWT	0,82	0,1	0,92

Source: Prognos Consultants, estimates for the European Commission

Sustainability of the IWT components is closely interconnected. If we refer to “Improve the competitiveness of shipping services” result area from Economic/Financial component, this has correspondent to 6,7 and 8 positions from operational table, respectively “Increase the efficiency of administration of navigation”, “modernize the barge fleet” and “improve port performance”. Similarly, we can discuss any of the components.
Using tool for components evaluation in terms of sustainability, with indicators scored from -3 to 3 scale, results a final sustainability indicators table (Table 2) and indicator-based assessment graph which you can see in figure 14.

Table 2
Sustainability indicators table

COMPONENTS	INDICATORS AND AREAS		SCORE
ECONOMICS & FINANCIAL	Increase and diversify IWT traffic levels.	Total traffic by tonnes and tonne-km carried Traffic carried by major commodities, by tonnes and tonne-km carried Traffic carried by each class of waterway	**2**
	Maintain or increase modal share carried by IWT.	Proportion of total traffic carried by IWT transport, by tonnes and tonne-km carried Proportion of international containers delivered to/from major seaports that are handled by IWT	
	Improve competitiveness of shipping services.	Index of average shipping freight tariffs for a fixed sample of routes and commodities Index of port charges for a fixed sample of routes and commodities Index of average delivery/collection time of international container by IWT between seaport and final customer for a fixed sample of routes	
	Ensure the financial sustainability of navigation infrastructure.	Total capital expenditure and sources of funding, including proportion of recovery from users Total operational expenditure and sources of funding, including proportion of recovery from users	
OPERATIONAL	Implement the EU plan and provincial navigation plans	Total length of waterways of each class operational at the end of each year, in total and compared to plan targets Total number of new berths of various types/capacities operational at the end of each year in total (and compared to plan targets if available)	**2**

COMPONENTS	INDICATORS AND AREAS		SCORE
	Increase the efficiency of administration of navigation	Indices of productivity for each navigation administration and in total (e.g. cubic meters dredged/dredging employee, or river-kms maintained/maintenance employee)	
	Modernize the barge fleet	Total fleet numbers by barge type/class Average capacity, power rating and age by barge type/class Number of new vessel registrations by barge type/class	
	Improve port performance	Total port and berth numbers by berth type/class Average capacity of berths by type/class Index of vessel turnaround times for a fixed sample of port terminals Number of ports with regular rail service connections	
ENVIRONMENTAL	Increase energy efficiency	Average liters fuel used/1,000 tonne-km of freight carried	**1,25**
	Reduce spillages of dangerous cargo on waterways	Total number of significant incidents Total spillage (1,000 liters)	
	Reduce spillages of dangerous cargo in ports	Total number of significant incidents Total spillage (1,000 liters)	
	Increase industry safety	Number of significant incidents involving death or serious injury Number of deaths and serious injuries to IWT shipping and port workers and to other people caused by IWT	
SOCIAL	Monitor impact of IWT and ports on waterside communities	Qualitative assessments	**0,5**
	Monitor social conditions in small barge sector	Numbers of individual owner-operators	
		14.2 Qualitative assessments	

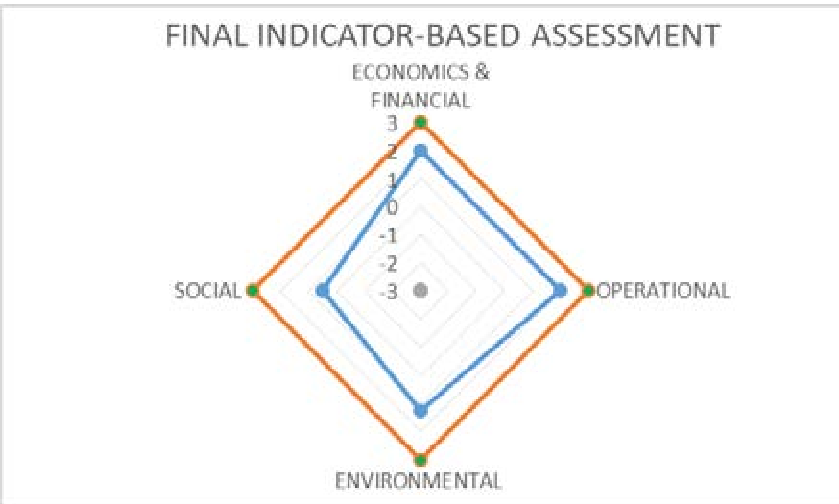

Fig. 14.
Indicator-based assessment graph

Inland navigation in Europe and in this case the waterway transportation between the Baltic and the Black Seas is neither automatically damaging nor beneficial to any sustainability component. This can be a very environment-friendly means of transport of goods and people if it is made within a framework of conditions: IWT have had and it always has some certain limits. With a careful planning and thoughtful consideration of how and under what circumstances navigation can be carried out it is possible to achieve a sustainable IWT.
For this, it is necessary that persons which are engaged in protecting the environment and managing water bodies to define more clearly the limits of the river related to the navigation. In a similar manner, the navigation managers should clarify the current and future needs of the inland navigation and how they want to achieve those most important objectives (not only in terms of infrastructure) in an environmentally sensible way.
A challenge – a new Vision requires:

- Taking into account the special environmental quality and requirements of each water body and the river sections and its tributaries;
- Working within the legal and policy frameworks that exist for integrated the river basin management and inland waterway development;
- Learning new experiences from other areas about the feasibility or negative impacts of certain waterway transportation, as well as about the introduction of the modern, integrated techniques of waterway and vessel design, market and logistics conditions, that limit or improve such transport;
- Before taking the investment decisions, sharing the information on the interests and needs of developing and the navigation strategies and actions for the waterway and river basin management that take account of these needs.

To achieve a Vision for a sustainable transportation there will be a need to focus on both questions of process and specific technical considerations related to the specific projects that form part of an overall strategy. A SWOT analyze is useful for developing a coherent mid-term vision which is affordable, sustainable and socially and economically acceptable (figure 15).

Fig. 15.
SWOT analyze for developing IWT mid-term strategy

The goal of this process is to achieve an agreement among the stakeholders involved in development and maintenance of the navigation/waterway transport and in managing the quality of revering resources – based upon the principles and criteria of the sustainability. It is a goal that is both necessary and realizable for all interests.
The challenge of a new waterway between the Baltic and the Black seas means to serve a wider social and economic purpose than they have in the past. The proposed Gdansk-Galati waterway can, therefore be expected to have a wide range of economic impacts:

- Tourism and recreation – the tourist and locals can offer opportunities for the economic impact for IWT;
- Boating – the new project offers the possibility to construct or to hire boats which can be used for the waterway activities;
- Visitors to the waterway – a new IWT will become attractive for the local residents and for tourists. For these groups, is necessary planning and investment which is required to maximize the level of activity that can be supported. If we are looking from an economic perspective, the attracting and retaining tourists from outside the area is very advantageous;

- Iconic structure – to complete the IWT it will be necessary to choose an engineering approach to overcome the height difference in this area. This is a good opportunity for the project to develop an iconic structure visible to the millions of visitors;
- Place shaping – is connected to both the recreational uses of the IWT and the iconic structure, the use of place shaping is to establish a local or regional identity and communicate it nationally or internationally;
- Transport is the natural use of the waterway system, competition from road and railways has meant that the waterways network in Europe is now used for bulky, non-perishable goods and some limited passenger transport. There are EU policies to increase the use of waterways as a transport conduit to reduce the social and environmental impacts from other forms of transport;
- Ecosystem services – IWT provides a range of what are known as ecosystem services, like as flood control and water transport. While these benefits are difficult to cost, they contribute to a sustainable economic development; and
- Property uplift and regeneration – Waterfront locations will raise the value of properties located close to them, for the residential properties by up to 20% of their value.

Prut River has been the object of several development projects and initiatives in the past decades. Hydropower potential was the primary objective of those initiatives, but the economic benefits could also result from its development as a navigable route.
Prut River had a strategic interest for policymakers and decision-makers from the three riparian countries: Ukraine, Moldova and Romania. Even if these interests have been often opposed or competitive, the riparian countries have understood that a sustainable development of the river based on mutual trust is necessary for the context in which Romania is already a member of the European Union and Moldova and Ukraine aspire to join the EU.
For the Prut River area, the economic, social or environmental benefit is included in the new concept of development for the river:

- A hydropower potential, the total estimated power of projects proposed in this concept is around 120 MW, which is a needed for Moldova who imports 80% of its energy requirement;
- Creating the navigable facilities of Prut River provides an alternative, more cost-effective exit to the Black Sea and a cheaper alternative to the rail and road transport, especially since all of Romania's existing waterways are concentrated in the south;
- The construction of the new bridges across the river would strengthen commercial ties between the three riparian states;
- The development of the irrigation networks and secure water supply for communities along the river;
- The implementation of flood protection systems.

The political impact of this initiative could improve the bilateral relations between Ukraine and Moldova with Romania and with the European Union, receiving support for integration and the adoption of the democratic values and principles towards a common future.

5. Conclusion

The conclusions can be structured on some relevant directions as follows:
1: A feasibility study is necessary to define the scope of best processes, institutional responsibilities and resource requirements for the implementation of a Comprehensive Inland Navigation Database for the new inland waterway.
2: Financial experts are commissioned to design a detailed financial investigation of the needs and funding sources of the inland waterway navigation infrastructure, including provincial, national and trans-border uses and sources of funds; quantify the long-term need and case for national and provincial budgetary financial support for every country.
3: The performance of countries' navigation authorities should be considered as a matter of the importance to the long-term sustainability of the inland waterway transport; their performance in terms of financial and operational records should be gradually improved to enable monitoring and comparisons of the value for money in the use of funds; the navigation authorities should be encouraged to undertake the pilot programs of the competitive maintenance procurement (including both specification-based and/or performance-based dredging and other maintenance contracts).
4: High priority is to be given to implementing the EU transport policy objectives, including for non-EU countries.
5: The navigation authorities from Romania, Ukraine, Moldova and Poland must continue to contribute actively to the inter-departmental consultations and planning of the water resources to ensure that the interests of the inland waterway transport are positively and comprehensively represented in decisions, policies and projects that may have an impact on the inland waterway transport industry; and similarly that the channels of communication with all stakeholders in the transport services industry, and with major freight shippers, are kept active and harmonious.
6: The port reform policies need to encourage more diverse participation and investment, and higher private participation in the specific terminals and competition in the port services where feasible.
7: The participant countries need to investigate how the market reach of the inland waterway transport can be expanded by improving the infrastructure and operational interfaces between the seaports and inland waterway transport and by improving inter-modal access at river ports, where such connections may be shown to be economically desirable.

8: The participant countries will prepare and disseminate the guidance to the inland waterway transport ports and operators about the importance of harmonious relationships with the local communities, the need for compliance with prevailing environmental standards, and practical measures that can be taken for the inland waterway transport activities to become a better 'neighbour' to others who live and work alongside rivers.
9: Market-based policies existing today for the barge transport services industry will be retained in which the competition is encouraged, industry capacity quotas and tariff regulations are avoided, and standards-based regulation is retained to ensure the navigational competence, safety and environmental performance.
10: The navigation authorities from Romania, Ukraine, Moldova and Poland must consider the case for the progressive introduction of vessel engine efficiency and emissions standards while increasing their efforts to ensure by the provincial navigation authorities comply with all EU environmental, safety and competency standards for vessels and crews.
11: Long-term policies for the sustainable development of the inland waterway transport industry should explicitly contain the mitigation measures for those small entrepreneurs, property owners, barge operators, who may be adversely affected by the modernization process.

ON A RIVER-COSTAL TUG OPERATION SAFETY ASSESSMENT IN IRREGULAR WAVES

Burlacu Elisabeta[1] , Pacuraru Florin[2], Domnisoru Leonard[3]
[1,2,3] *"Dunarea de Jos" University of Galati, Faculty of Naval Architecture, Romania*

Abstract: For inland and costal harbours cargo transport and special operations between the shipyards, a specific type of tug has been designed to cover the river-costal routes. One of the design criteria for the tug operation safety assessment is based on the seakeeping analysis in irregular waves. As study case we have analysed the behaviour of a river-costal tug with 48 m total length, one loading condition. The design route includes the connection between the Romanian harbours and shipyards, at the Danube River and at the Black Sea Coast. According to the navigation scenario in irregular waves, the statistical significant wave height limits are considered with maximum levels on the river route 2 m and on the costal route 4 m. The extreme condition of 5 m irregular wave significant height is also considered. The numerical analysis is done using the eigen program DYN, modules for seakeeping (OSC), with two main steps: response amplitude operators and statistical significant response in irregular wave's computation. The analysis is developed considering: speed range 0-20 km/h, wave significant height range 0-5 m and heading angle range 0-360 deg. This study analyzes the river-costal tug navigation capabilities on inland and costal waterways, by the design seakeeping safety criteria.

Keywords: river-costal tug, irregular waves, safety operation on inland and costal waterways, design seakeeping criteria.

1. Introduction

For the Romanian inland and costal waterways transport, one of the most used navigation route is between the harbours and shipyards at the Danube River and those at the Black Sea Coast (Figure 4). Besides the standard cargo transport with barge convoys, special operations as floating docks or ship construction blocks relocation between the shipyards have to be done. For this purpose, several river-costal tugs have been designed (ANR, 2006), that have to navigate also in irregular wave conditions. Among many design criteria by shipbuilding rules (DNVGL, 2018), the tug navigation operations (DNV, 2014) have to be assessed by the seakeeping safety criteria. This study is focused on the seakeeping analysis of a Romanian river-costal tug for the navigation safety assessment, under several wave conditions.

2. The Seakeeping Analysis Method

The seakeeping analysis method is based on a linear strip hydrodynamic theory for response amplitude operators *RAO* computation (Söding, 1982; Voitkunski, 1985; Domnisoru, 2001; Kornev, 2012) and the short-term statistical response prediction in irregular waves' theory (Price and Bishop, 1974; Bertram, 2000; Lewandowski, 2004, DNV, 2014).
For the numerical seakeeping analysis we have used the eigen program DYN (Domnisoru, 2017), with the logical scheme presented in Figure 1, with five main modules. The last version of the DYN program has been validated by towing tank experimental data, including head, beam and follow sea cases (Obreja et al, 2017).
Module 1 includes the pre-processing of the input ship data: CAD model of the external shape, mass diagram, hydrostatic curves, still water equilibrium position and transversal stability diagrams. Also, the ship's speed range and the irregular waves' characteristics are selected.
Module 2 includes the computation of the hydrodynamic radiation, inertial and damping, terms of the motion equations system, by a 2D potential flow model, where the ship's stations are parameterized by a conformal transformation (Voitkunski, 1985; Domnisoru, 2001), being constant in time and taking as reference the ship's still water position. Also, the hydrostatic term is computed, using a linearized formulation. The hydrodynamic diffraction term is computed for a regular wave excitation with unit amplitude.
Module 3 includes the computation of the response amplitude operators *RAO*, by solving in the frequency domain the motions equation system for regular wave with unit amplitude. There are considered the following parameters: the wave circular frequency in the range ω=0-3 rad/s, with step 0.001 rad/s; ship-wave heading angle in the range μ=0-360 deg., with step 5 deg.; tug speed values v=0, 5, 6, 10, 12, 15, 18, 20 km/h. For the river-costal tug the motions on heave, pitch and roll are analyzed.
Module 4 includes the computation of the short-term statistical most probable *RMS* motions and RMS_{ac} accelerations for a selected irregular waves' power density spectrum. At the Black Sea area, for many years the sea state has been recorded, including also several extreme storms (Rusu et al, 2014). For the Romanian Black Sea Coast the long-term wave significant height histogram is presented in Figure 6, with the occurrence probability of 99,5% of the waves in the range of H_s=0-4 m. Figure 5 presents the Black Sea Romanian Costal average wave power density spectrum $\Phi_w(\omega)$.
Module 5 includes the computation of the admissible polar diagrams for the navigation safety, expressed in terms of limit significant wave height $H_{slimit}(v,\mu)$ and Beaufort level $B_{limit}(v,\mu)$. The polar diagrams are obtained by the seakeeping criteria, formulated as most probable admissible values, applied for: vertical motion at aft, mid and fore; pitch and roll motion; heave, pitch and roll accelerations. For the navigation capabilities assessment of the river-costal tug the following limit significant wave height levels are considered: on the river route IN 0.6, 1.2, 2 m and on the costal route C 2.5, 3, 4 m.

Seakeeping Analysis / Package code DYN – modules OSC

Module 1
- Input data: ship shape and mass, speed range, wave's characteristics
- Computation of ship still water equilibrium position
- Computation of the transversal stability diagrams

Iterations on ship speed range $v = v_{min} \div v_{max}$
and on ship-wave heading angle $\mu = 0 \div 360\, deg$.

Module 2
Computation of the terms of the time domain motion equations system for regular wave with unit amplitude $a_w = 1$ and a range of circular frequencies $\omega = 0 \div \omega_{max}$.

$$([M]+[A(\omega_e)])\{\ddot{Q}(t)\}+[B(\omega_e)]\{\dot{Q}(t)\}+[C(\omega_e)]\{Q(t)\}=\{\overline{F}_w(\omega_e)\}e^{-i\,\omega_e t}\,;\ \{Q(t)\}=\{\overline{Q}(\omega_e)\}e^{-i\cdot\omega_e t}\,;\ \omega_e=\omega-\omega^2/g\ v\cos\mu$$

- the ship's own mass matrix: $[M]$;
- hydrodynamic radiation (inertial and damping) and hydrostatic matrix: $[A(\omega_e)],[B(\omega_e)],[C(\omega_e)]$;
- hydrodynamic diffraction vector from the regular wave excitation: $\{\overline{F}_w(\omega_e)\}$;

where: g is the gravity acceleration, ω_e is the ship-wave encountering frequency, $\{\overline{Q}(\omega_e)\}$ is the motion amplitude.

Module 3
Computation of response amplitude operators RAO_j for j motion components, solving in the frequency domain the motions equation system for regular waves $a_w = 1$ and $\omega = 0 \div \omega_{max}$.

$$\{\overline{Q}\}=[D(\omega_e)]^{-1}\{\overline{F}_w\};\quad \{\overline{Q}\}=\{Q_1\}+i\,\{Q_2\};\quad [D(\omega_e)]=-\omega_e^2([M]+[A(\omega_e)])-i\,\omega_e[B(\omega_e)]+[C(\omega_e)]$$

$$RAO_j(v,\omega,\mu)\big|_{load\ case}=\sqrt{Q_{1j}^2+Q_{2j}^2}$$

Module 4
Computation for each response component j the short-term statistical most probable motion RMS_j and acceleration $RMS_{ac\,j}$ values for irregular waves with power density spectrum $\Phi_w(\omega_e)$.

$$\Phi_j(\omega_e)=RAO_j^2\cdot\Phi_w(\omega_e);\ m_{0j}=\int_0^\infty \Phi_j(\omega_e)d\omega_e\,;\ m_{4j}=\int_0^\infty \omega_e^4\Phi_j(\omega_e)d\omega_e\,;\ RMS_j=\sqrt{m_{0j}}\,;\ RMS_{ac\,j}=\sqrt{m_{4j}}$$

Module 5
Computation of the admissible polar diagrams in terms of limits for significant wave height $H_{s\,limit}(v,\mu)\big|_{load\ case}$ and Beaufort level $B_{limit}(v,\mu)\big|_{load\ case}$, by the seakeeping criteria on the main ship's dynamic components.
- vertical motion at aft, mid and fore, by combination of heave, pitch and roll motions most probable values:

$$RMS_z\big|_{aft,fore}=RMS_\xi+RMS_\theta(L/2\pm LCF)+RMS_\varphi\,B/2+H_s/4\,;\ RMS_z\big|_{mid}=RMS_\xi+RMS_\varphi\,B/2+H_s/4$$

$$RMS_{z\,max}\big|_{aft,mid,fore}=H_{aft,mid,fore}-F_s-T_{aft,mid,fore}\ge RMS_z\big|_{aft,mid,fore}\ ;\ RMS_{\zeta ac\,max}=0.1g\ge RMS_{\zeta ac}$$

- pitch motion most probable values:

$$RMS_{\theta\,max}=3\,deg.\ge RMS_\theta\ ;\ RMS_{\theta ac\,max}=max\{0.15g/(L/2\pm LCF)\}\ge RMS_{\theta ac}$$

- roll motion most probable values:

$$RMS_{\varphi\,max}=8\,deg.\ge RMS_\varphi\ ;\ RMS_{\varphi ac\,max}=0.1g\cdot 2/B\ge RMS_{\varphi ac}$$

Plot diagrams: $RAO_j(v,\omega,\mu)\big|_{load\ case}$ and $H_{s\,limit}(v,\mu)\big|_{load\ case}$ & $B_{limit}(v,\mu)\big|_{load\ case}$ / END DYN

3. The River-Costal Tug Numerical Model

The numerical seakeeping analysis is developed for a Romanian river-costal 4000 HP tug with the main characteristics presented in Table 1 and the offset-lines presented in Figure 2. The tug hull numerical model has 83 stations, with finer division at both extremities. Figure 3 presents the computed tug righting lever curve. The tug has a significant transversal stability, making possible to linearize the roll restoring term over more than 15 deg. roll angle.

4. The Response Amplitude Operators of the River-Costal Tug

For the river-costal tug (Figure 2, Table 1) the response amplitude operators on heave, pitch and roll motions are obtained, by program DYN (Figure 1) modules 2 and 3.

Figures 7.a,b and Figures 8.a,b present the heave and pitch *RAO* for the speed 0 and 20 km/h, heading angle 0, 45, 90, 135, 180 deg. Figures 7.c,d and Figures 8.c,d present the heave and pitch *RAO* for heading angle 90, 180 deg. and the full range of tug speed 0 – 20 km/h.

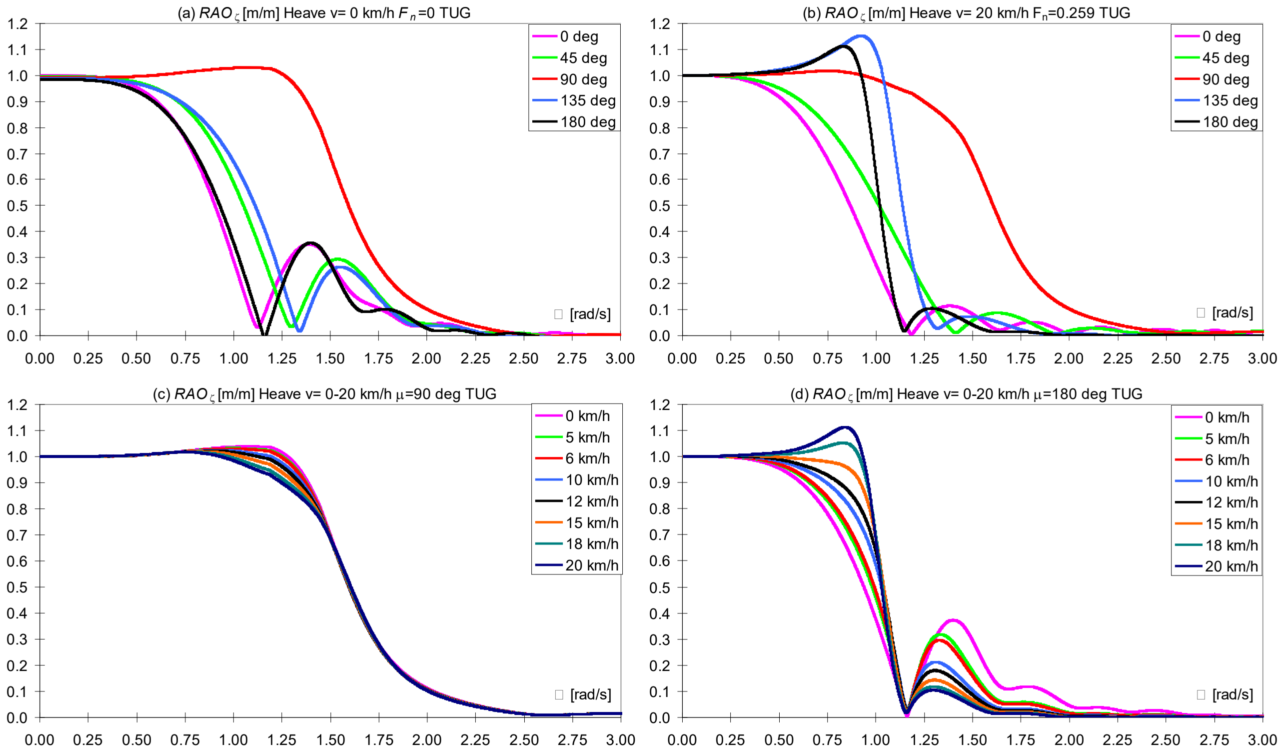

Fig. 7.

RAO_ζ[m/m] heave : a) v=0 km/h; b) v=20 km/h; c) v=0-20 km/h μ=90 deg; d) v=0-20 km/h μ=180 deg

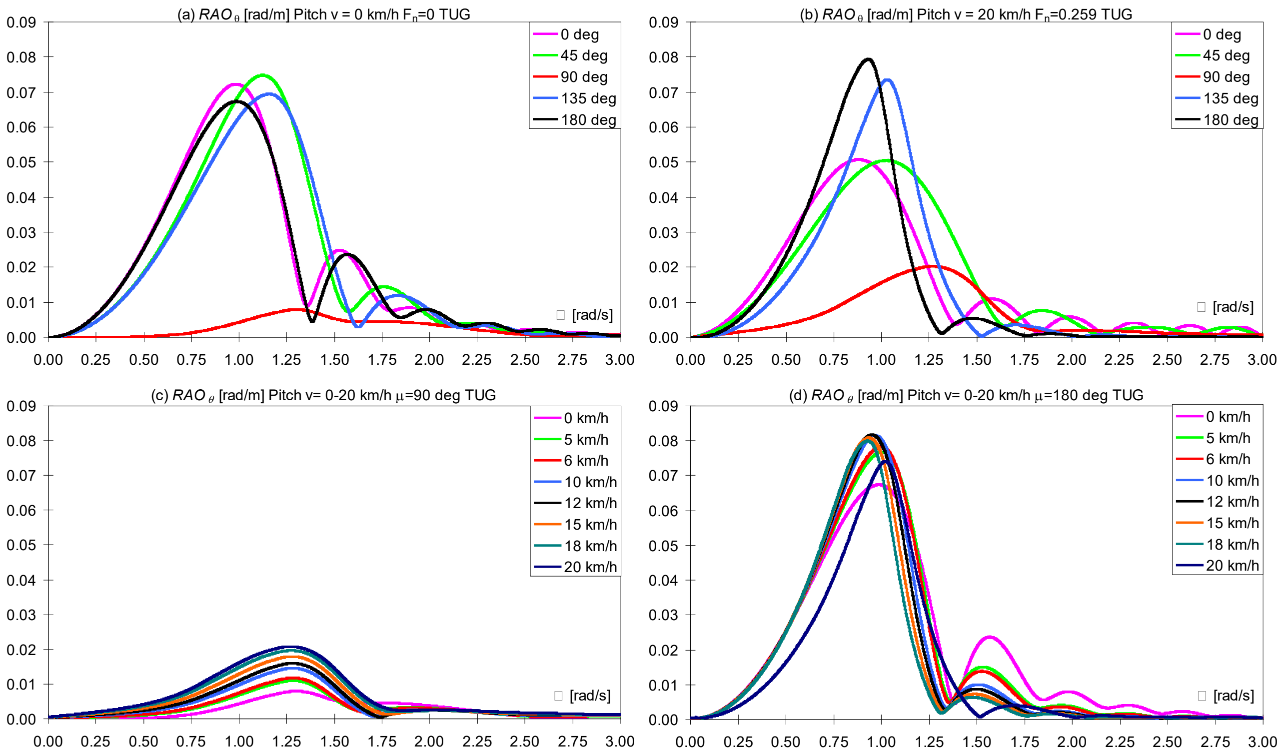

Fig. 8.

RAO_θ[rad/m] pitch : a) v=0 km/h; b) v=20 km/h; c) v=0-20 km/h μ=90 deg; d) v=0-20 km/h μ=180 deg

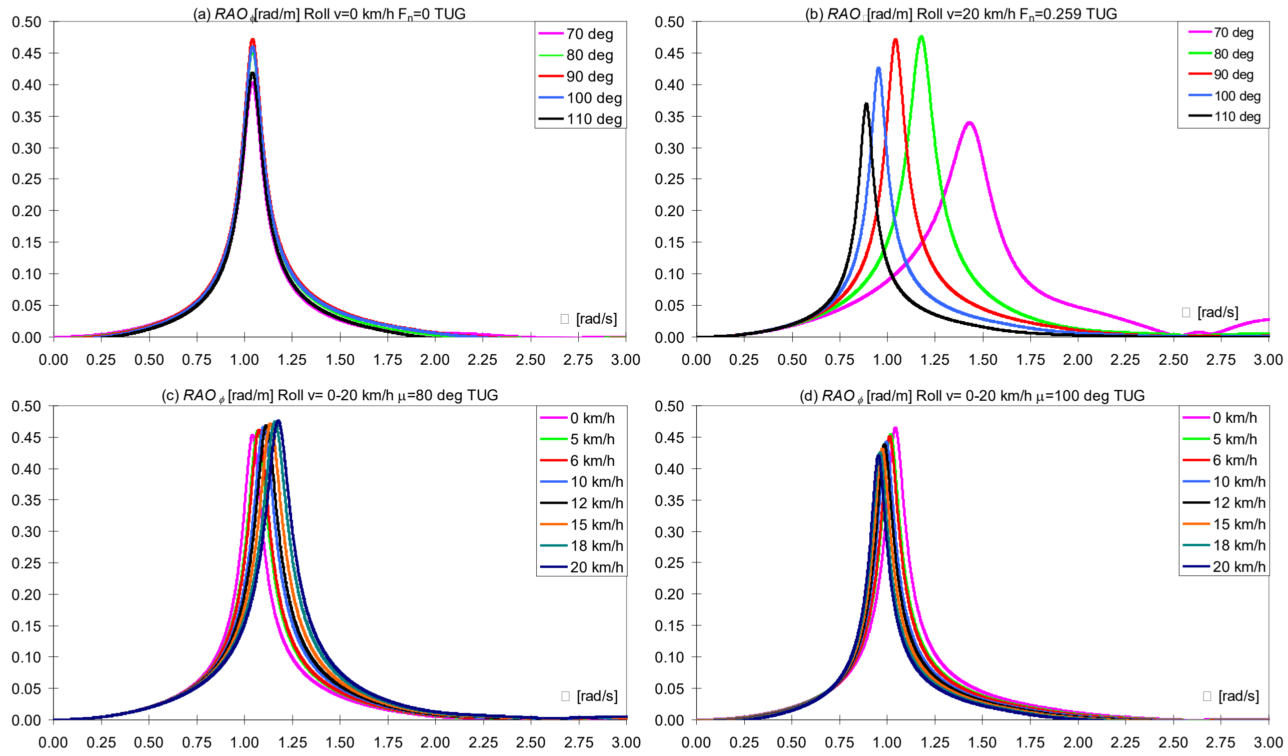

Fig. 9.

RAO_{φ}[rad/m] roll : a) v=0 km/h; b) v=20 km/h; c) v=0-20 km/h μ=80 deg; d) v=0-20 km/h μ=100 deg

For beam sea condition (90 deg.) the tug speed influence on heave and pitch *RAO*’s is very reduced. For head waves condition (180 deg.) the tug speed influence on heave and pitch *RAO*’s is significant.
Figures 9.a,b present the roll *RAO* for the speed 0 and 20 km/h, heading angle 70, 80, 90, 100, 110 deg. Figures 9.c,d present the roll *RAO* for heading angle 80, 100 deg. and the full range of tug speed 0 – 20 km/h.
Although for 90 deg. heading angle the tug speed has no influence on roll *RAO*, in the range of 70-110 deg. the speed influence occurs.

5. The Statistical Short-Term Response of the River-Costal Tug

For the river-costal tug (Figure 2, Table 1) the statistical most probable response *RMS* on heave, pitch, roll motions and accelerations are obtained, by DYN program (Figure 1) modules 4 and 5, using the *RAO’s* function from Section 4 and the irregular waves with the power density spectrum from Figure 5. Based on the significant wave height histogram (Figure 6), the waves' probability of occurrence and exceeding are predicted.
For the vertical motion there are considered three reference points, aft-side, mid-side, fore-side, so that a combined heave, pitch and roll motions criteria is applied. Due to the non-symmetric hull at amidships reference, we have considered the maximum between aft and fore vertical pitch induced accelerations.
Figures 10.a,b,c present the maximum statistical most probable response for combined vertical motions.
Figure 11.a and Figure 12.a present the maximum statistical most probable response for pitch and roll motions.
Figure 10.d, Figure 11.b and Figure 12.b present the maximum statistical most probable response for heave, pitch and roll accelerations.
Considering the tug speed 0 and 20 km/h, for the extreme sea state condition H_s=5m with 0.1% probability of occurrence (Figure 6), Table 2 presents the maximum maximorum most probable tug motions and accelerations. Also, the admissible values for the seakeeping criteria (Figure 1, module 5) of the river-costal tug are presented in Table 2.
The highest speed influence is on heave and pitch accelerations, medium on heave and pitch motions and very reduced on roll motions and accelerations. Vertical aft and fore motions, heave acceleration, pitch motion and acceleration have the maximum values in head waves conditions. Vertical midship motion, roll motion and accelerations have maximum values in beam sea conditions. The highest overcome is recorded on the pitch acceleration criteria, by 39.49%.
Figures 13.a,b and Figures 14.a,b present the polar diagrams for navigation safety in terms of wave significant height $H_{s\ limit}(v,\mu)$ and Beaufort level $B_{limit}(v,\mu)$ for the river-costal tug, by the seakeeping criteria from Figure 1, module 5.
Considering the main heading angles reference, follow and quarter-stern sea condition (0-45 deg), beam and quarter sea condition (70-110 deg.), head and quarter-bow sea condition (135-180 deg.), Table 3 presents the resulting sea state level limits for tug navigation safety and Table 4 presents the seakeeping criteria leading to restrictions. For the inland waterway there are no restrictions IN(2.0). For the coastal waterway, for the speed range 0-6 km/h the main restrictions occur at beam sea condition C(3.80) and in the speed range 10-20 km/h the main restrictions occur at head and quarter-bow sea condition C(3.67) – C(2.41).

6. Conclusion

The operation safety of a river-costal 4000 HP tug (Figure 2 and Figure 3, Table 1) has been analyzed by eigen program DYN (Figure 1), with seakeeping criteria formulated on the main motions and accelerations, heave, pitch and roll (module 5, Figure 1) and irregular waves specific to the river-costal navigation route (Figure 4), from the Danube River (H_s≤2m) to the Black Sea Coast (H_s≤5m), (Figure 5 and Figure 6).
The analysis of the response amplitude operators *RAO* (Figures 7,8,9.a,b,c,d) points out that the tug speed changes in the range of 0-20 km/h lead to the increase of the heave and pitch motions at head sea condition. At beam sea condition, for the tug main motions the speed influence becomes much reduced. Taking as reference the extreme condition of the irregular waves with significant height H_s=5m on the Black Sea Coast (Figures 5,6), for the tug speed changes in the range of 0-20 km/h, the maximum most probable *RMS* values (Figures 10,11,12) exceed the admissible seakeeping criteria (Table 2) as following: vertical combined motions aft 14.08-18.69%, midship 25.44-26.03%, fore max. 4.26%; pitch motion 8.12-8.79%; heave acceleration max. 25.32%; pitch acceleration 39.49%. The tug roll motion and acceleration are in the limits of the seakeeping criteria, due to the significant transversal stability (Figure 3). Based on the tug speed influence on *RAO*'s functions and the maximum statistical most probable responses, the seakeeping criteria that lead to restrictions for the river-costal tug navigations are indentified (Table 4). Taking as reference the navigation safety polar diagrams H_{slimit}, B_{limit} (Figure 13 and Figure 14, Table 3) for Danube River waterway the tug has no navigation restrictions, H_{slimit}=2m. For Black Sea Coast waterway, for the tug speed range 0-10 km/h the navigation restriction is H_{slimit}=3.67-3.80m, close to the H_s=4m limit, B_{limit}=6.70, with the exceeding probability $P[H_s>3.80\text{m}]\approx 0.9\%$, and for the tug speed range 12-20 km/h the restriction is H_{slimit}=2.41-3.15m, B_{limit}=5.26-6.13, with the exceeding probability $P[H_s>2.41\text{m}]\approx 4.8\%$. It results that in order to ensure the 4000 HP tug navigation safety on the costal waterways, the tug speed should be reduced bellow 10 km/h, according to the sea state conditions.

Abstract: Passenger ports are providing maritime services that are necessary to satisfy the demands of the users and serve also to provide a direct service instead of using road connections in the narrow places. Here, a model for optimizing the size of a ferry fleet in a passenger port is proposed. The model is done in the case of the Boka Kotorska Bay where there is an intensive need to provide a ferry service of passengers at the proposed routes. The numerical experiment includes the heterogenous fleet in transport capacities. Here, the possibility to transfer passengers inside the bay is of utmost importance especially during the summer peak season. In addition, the analysis also reports the environmental aspects in the sense of emission estimation that affects the inhabitants located at the coast of the bay. However, this paper represents one of the initiatives to improve the ferry passenger service in the area.

Keywords: passenger port, analysis, model, ferry service.

1. Introduction and Related Literature

Investigations about the ship fleet size have been investigated a lot in the previous period. In this paper, we pay attention to the ferry passenger service necessary to transport local inhabitants and tourist to the appropriate locations similarly as done in Škurić and Maraš (2017). We combine the estimation of emission produced from the ferry ships and calculate the level of NO_X, SO_2 and PM that are recognized as ones of the biggest air pollutants. The investigation of emission inventories represents a very important aspect of the environmental protection of the coast. Generally, together with cruise ships, ferry ships are treated to be significant polluters in the passenger ports. To calculate the level of emissions, it is necessary to analyze the effects of the transport of ferry ships, which are primarily related to their engines. Despite the fact that diesel engines achieved fuel efficiency in consumption, they are still not insignificant source of emissions of NO_X, SO_2 and PM. By combining propulsion characteristics of ferry passenger ships, the aim is to point out their differences and the possibilities for reducing emissions through the optimal allocation of the fleet. Regarding the calculation of emission from ferry passenger ships, it should be noticed some assumptions regarding the navigational characteristics of the area. Winebrake et al. (2005) applied MIP in the case of New York and New Jersey passenger ports for calculating NO_X and PM. Some of the important investigations are done by Saxe and Larsen (2004) and De Meyer et al. (2008) that calculated emission for Dannish and Belgian ports. On the other hand, one of the most important studies for passenger ports are done by Cooper and Andreasson (1999), Cooper (2001), Corbett and Farrell (2002) and Tzannatos (2010a,b). Similar methodology has been used in Chang and Wang (2012) where authors compared the techno-economic effectivity of the ships at the Port of Kaohsiung. The cruise ship emission inventories are described and reported in Dragović et al. (2015) and the cases of Dubrovnik and Kotor cruise ports. Ship-activity phases in ports from the perspective of calculating emission inventories are presented in McArthur and Osland (2013), Castells Sanabra et al. (2014), Song (2014), Maragkogianni and Papaefthimiou (2015) and Tichavska and Tovar (2015a,b).
However, the analysis provided in this paper comprehends modeling the optimal ferry passenger fleet size in the case of minimizing the level of emission from the ferry ships. The structure of the paper is as follows. In Section 2 is provided the integer linear model formulation. Numerical experiment is described and validated in Section 3 while Section 4 reports the results obtained from the case study. Section 5 gives concluding remarks.

2. Model Description

In this section, we describe the model and input data for calculating emission level from ferry ships. It also includes the model formulation in the case of minimizing the emission inventories. Such study has been previously done in Dragović et al. (2015) for the cruise ships. The methodology provided in initial emission calculation is accepted from mentioned study.
Like in many other papers, in the case of ferry ships, the role of main and auxiliary engines is necessary to calculate the emission. These engines are characterized to be diesel and the load factor of auxiliary engines is accepted to be 43% according to the analyses provided by ENTEC (2002), CARB (2004) and ICF (2009). Additionally, the load factor of main engines is 45%. In the case of transporting passengers in Boka Kotorska Bay (Figure 1), ferry ships are passing through three different phases: reduced speed zone with the speed limit of 12 knots, maneuvering while approaching the port and berthing or anchoring. The data with regards to the load factor for each ship-activity phase are given in Table 1. Similarly, in Table 2 are given emission factors for each ship-activity phase and in accordance to the different air polluters (CARB, 2004).

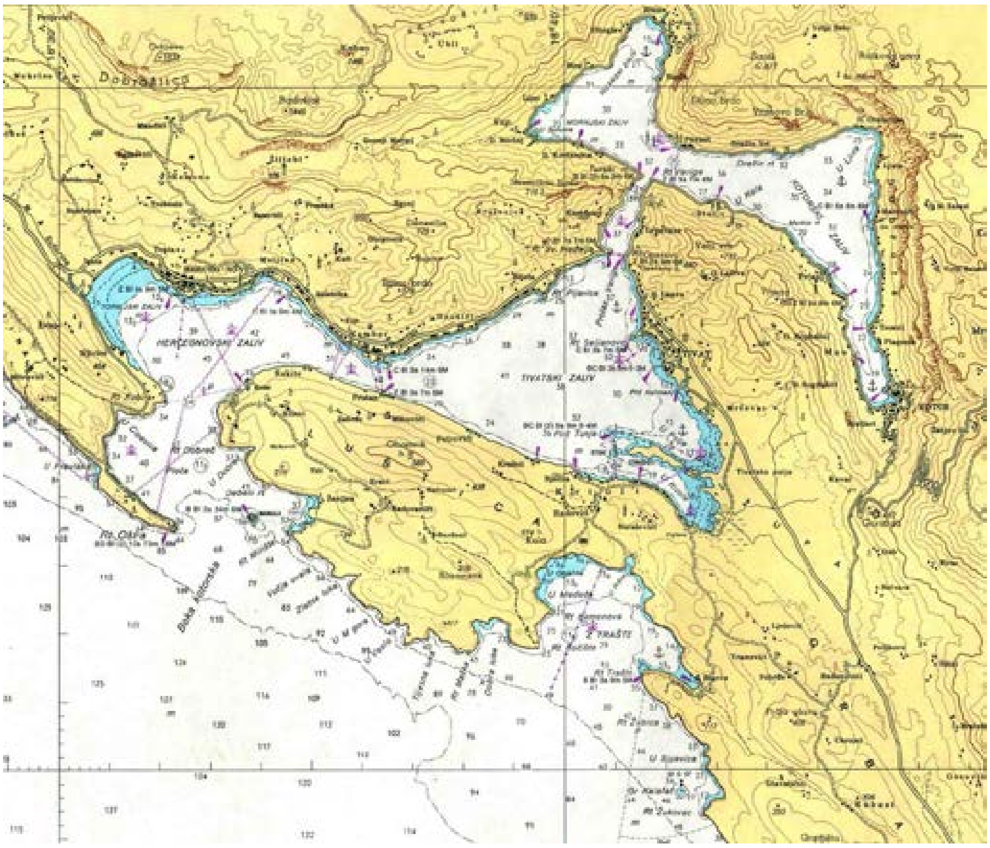

Fig. 1.
Boka Kotorska Bay: study area (PKAD, 2015)

Table 1
Load factors of ferry ships

	Reduced speed zone	Maneuvering	Berth/Anchor
Main engine (ME)	0.45	0.45	0.20
Auxiliary engine (AE)	0.43	0.43	0.20

Table 2
Emission factors of ferry ships

Emission factor (g/kWh)	**Ship's activity**	
	Reduced speed zone/ Maneuvering	**Berth/Anchor**
NO_X	5.10-15.34	11.6
SO_2	11.7-12.9	12.6
PM	0.20-0.70	0.08

The emission produced from the ferry ships can be calculated according to (1) and applied in the case of NO_X, SO_2, and PM.

$$E = E_{RB} + E_M + E_{V/S} \tag{1}$$

where E_{RB} represents the emission of ferry ships in the first activity phase (reduced speed zone), E_M is the emission of ferry ships during a maneuvering and $E_{V/S}$ represents the emission of ferry ships at berth or anchor. Based on the methodology applied in Dragović et al. (2015) and data from Tables 1 and 2, for each activity the emission is separately calculated (formulae (2-4)).

$$E_{RB} = [T_{RB} \cdot [(P_{ME} \cdot LF_{ME} \cdot \sum EF_{ME_e}) + (P_{AE} \cdot LF_{AE} \cdot \sum EF_{AE_e})]_{RB}] \cdot 10^{-6} \tag{2}$$

$$E_M = [T_M \cdot [(P_{ME} \cdot LF_{ME} \cdot \sum EF_{ME_e}) + (P_{AE} \cdot LF_{AE} \cdot \sum EF_{AE_e})]_M] \cdot 10^{-6} \tag{3}$$

$$E_{V/S} = [T_{V/S} \cdot [(P_{ME} \cdot LF_{ME} \cdot \sum EF_{ME_e}) + (P_{AE} \cdot LF_{AE} \cdot \sum EF_{AE_e})]_{V/S}] \cdot 10^{-6} \tag{4}$$

where T_{RB}, T_M and $T_{V/S}$ represents travel times of each activity in hours, P_{ME} and P_{AE} are main and auxiliary engines' power in kW, LF_{ME} and LF_{AE} are load factors of main and auxiliary engines while $\sum EF_{ME}$ and $\sum EF_{AE}$ indicate sum of all emission factors *e* for each polluters for main and auxiliary engines in g/kWh.

2.1. Formulation

After the calculation of total emission produced by ferry ships, we propose a model for minimizing the total ship emission and the allocation of the ferry fleet. The integer linear programming model is based on the supposed demand for transportation that is expressed as a number of passengers that need to be transported. Therefore, we have the following parameters and decision variables:

n – number of ferry ship types,
r – passengers' demand,
x_{ij} – number of ferry ship of *j* type that are assigned to the demand *i*,
e_{ij} – emission (in tons) per one ferry ship of *j* type that is available for demand *i*,
p_{ij} – capacity of ferry ship of *j* type in planning horizon available for demand *i*,
P_i – number of passengers that needs to be transported in planning horizon according to the demand *i*,
t_{ij} – operational time (in hours) of ferry ship of *j* type available for demand *i*,
T_i – maximal time (in hours) needed for passenger transportation by ferry ships according to the demand *i*.

The objective is to minimize the level of emission.

$$\min \sum_{i=1}^{r} \sum_{j=1}^{n} e_{ij} x_{ij} \tag{5}$$

s.t.

$$\sum_{i=1}^{r} \sum_{j=1}^{n} p_{ij} x_{ij} \geq P_i \tag{6}$$

$$\sum_{i=1}^{r} \sum_{j=1}^{n} t_{ij} x_{ij} \leq T_i \tag{7}$$

$$\sum_{i=1}^{r} x_{ij} \geq 1 \tag{8}$$

$$x_{ij} \in \{0,1\} \qquad i = 1,2,\ldots,r \qquad j = 1,2,\ldots,n \tag{9}$$

The objective (5) is related to minimization of total ferry ship emission. Constraint (6) represents the condition of available seats for passenger transportation onboard ferry ship that needs to be equal or greater the demand. Constraint (7) implies that the operational time of ferry ship cannot be greater than the service time (maximal time of passenger transportation). More than one ferry ship can be allocated to each demand as proposed in constraint (8). Constraint (9) implies the status of *n* and *r* as well as the binary status of x_{ij}.

3. Numerical Experiment

The numerical analysis is done for the Boka Kotorska Bay and the demand for passenger transportation during a specified time in September 2015. Applying formulae (1-4), the total emission per hour of ferry ships is calculated. After that, the integer linear programming model is applied and coded in MATLAB 7.12.0. The output results indicate the optimal allocation plan and assignment of ferry ship necessary for minimizing the level of emission for NO_X, SO_2 and PM. The input data for the model are given in Table 3 and according to the ferry ship data obtained from http://www.naviecapitani.it/. Here we propose the five types of ferry ships' capacity denoted as FT1, FT2, FT3, FT4 and FT5. The sum of available ships is 18. Their total capacity is 4275 passengers per day. The details for these ships are also provided in Table 3.

Table 3
Input data

	Number of ships	Total engine power (kW)	Ship's capacity	Total ships' capacity
FT1	3	820	499	1497

FT2	4	1402	134	536
FT3	3	2162	350	1050
FT4	4	162	48	192
FT5	4	1646	250	1000

The real-case emission and ferry ship assignment are provided in Table 4. Applying (1-4), in Table 4 are given the output results of the total emission per ferry ship type. The calculation is done for five days with specified operational time and supposed demand of transportation. The emission in tons per hour and total emission during a day is reported. The total emission for five days is 14.142 tons.

Table 4
Assigned ships

Date	Operational time (h)	Demand	Assigned ships					Emission (t/h)	Total emission (t/day)
			FT1	FT2	FT3	FT4	FT5		
1/9	5.66	335	0	0	3	0	4	0.144	1.852
	7.20	1511							
2/9	8.00	1742	0	0	3	0	4	0.144	1.843
	4.80	130							
3/9	8.00	696	2	0	0	0	0	0.015	0.336
	14.40	130							
4/9	7.20	1755	0	0	3	0	4	0.144	3.341
	16.00	34							
5/9	4.80	2023	3	4	3	0	4	0.217	6.770
	8.00	1325							
	8.80	172							
	9.60	135							

4. Model Application: Results

Using the integer linear model and formulae (5-9), the improved results about the total level of emission of ferry ships and their assignment per daily demand is reported in Table 5. As it can be noticed, the level of emission is drastically reduced to 7.7292 tons. The model reached to optimize the total emission (to minimize it) as to propose a new allocation of ferry ships to satisfy the passengers' demand.

Table 5
Results of a model

Date	Operational time (h)	Demand	Results of assigned ships					Emission (t/h)	Total emission (t/day)
			FT1	FT2	FT3	FT4	FT5		
1/9	5.66	335	3	0	0	3	1	0.044	0.5660
	7.20	1511							
2/9	8.00	1742	3	0	0	3	1	0.044	0.5632
	4.80	130							
3/9	8.00	696	2	0	0	0	0	0.014	0.3136
	14.40	130							
4/9	7.20	1755	3	0	0	1	1	0.041	0.9512
	16.00	34							
5/9	4.80	2023	3	0	3	3	4	0.171	5.3352
	8.00	1325							
	8.80	172							
	9.60	135							

It is interesting to note that in the first demand from the date 1/9, the model outputs seven ferry ships that are available to transfer 1891 passengers (45 more than the demanded number). Seven ferry ships are also allocated to the second demand that can transport 19 passengers more than requested. Third case includes two ferry ships and 173 extra seats for passengers, while five ferry ships with 1795 passenger seats are enough to satisfy the demand in fourth case. Regarding the fifth date, 13 ferry ships are allocated to transfer 36 passengers more than requested. Even though the model provided better results for the emission and allocation of ferry ships, there is a space for further improvement of the model that can be pointed out to its complexity.

5. Conclusion

The optimization of ferry passenger fleet size is analyzed in this paper. The numerical experiment is provided in the case of local ferry passenger transportation in Boka Kotorska Bay. The methodology is combined with the estimation and minimization of emission from ferry ships. The analysis included three polluters, namely: NO_X, SO_2 and PM. The optimal allocation of ferry ships is formulated by the integer linear programming model.
The obtained output results indicate that with the optimal assignment of ferry ships, the emission can be drastically reduced. The methodology for calculating emission is consisted of the data regarding the ship-activity phases. In addition, for this experimental analysis, statistical data had to be provided. Since the expectations are that the number of passengers i.e. local inhabitants and especially tourist will grow even more in the next period, this research can be improved in the sense of including some other parameters and work on its complexity. On the other hand, further research should be directed to the promotion of super-low-emission-ferries that can operate on the local level such as the area of Boka Kotorska Bay. This will affect the sustainable development of the whole area.

Abstract: High energy consumption, CO_2 and other emissions related to transport require a transformation of the mobility system. Although recently e-mobility is being discussed as a possible solution, neither a breakthrough of technology, nor market penetration happened so far. The approach of the multi-level perspective (Geels, 2012), which explains socio-technical system change, might be helpful to understand the barriers for a transformation of the system towards sustainable mobility based on technological innovation. The model describes how innovation is absorbed by and transforms an existing "regime", consisting of economy, society, politics, technology, etc. We used this approach to examine the potential of e-mobility for systemic change in a case study of Lake Constance region. The analysis focuses on cooperation between the stakeholders in e-mobility, illustrating the regime's response to the technology. Barriers and starting points to support a transformation process were identified. Even if electric mobility is not necessarily sustainable, the case study allows for general conclusions concerning the spread of new technologies and mobility concepts. Thus, findings may be applied to the change process of todays' fossil fuel driven mobility regime. Results reveal a fragmented e-mobility market with various technical standards, players and their offers. Information about services and accessibility is difficult to get for customers. Partially cooperation between operators of charging stations exists in roaming agreements, which allow customers to use charging stations independently of their original providers – but they do not cover the whole region. At the same time there is potential for joint mobility services, e.g. connecting public transport with e-bike rental. Although experts clearly see the need for joint mobility services, the interest of the relevant players is low. They wait for external actions rather than actively shaping the transformation towards e-mobility. Thus, a change of the current mobility regime requires coordination and cooperation within different fields, ranging from technical standards over information to interlinking different services, including existing public transport and active mobility modes.

Keywords: transformation, governance, e-mobility, stakeholders.

1. Introduction

In Europe, e-mobility is being forced in order to reduce greenhouse gas emissions and emissions of particles within cities. For example, the German government has been promoting electric mobility for years and 2016 even intensified related measures. The goal is to bring one million electric vehicles onto Germany's roads by 2020. The support programme focuses on temporary purchase incentives, the expansion of the charging infrastructure and public procurement of electric vehicles (BMWi, 2018). France also supports electric mobility with a purchase bonus and subsidises the construction of charging stations (Electrive, 2017). With these measures, France plans to terminate the sale of cars with internal combustion engines by 2040 (BBC, 2017). Although these policies are meant to increase sustainable mobility, it has to be mentioned that electric mobility is not synonymous with low CO_2-emissions and resource consumption in general. If driven by alternative energy electric mobility might contribute to lower such emissions (e.g. Van Mierlo, Messagie and Rangaraju, 2017; Hawkins *et al.,* 2013), but energy and resource consumption remains critical if mass production of electric vehicles takes place (Althaus *et al.,* 2010). The study reported here does not investigate the potential for emission savings, but the potential distribution of a new technology. Results should also allow to derive conclusions for other technologies or mobility concepts more clearly supporting a transformation of the transport system towards sustainable mobility.

2. Potential and Barriers for System Transformation in Mobility

2.1. System Change Through Technical Innovation

New technologies provide options to improve the mobility system but simply implementing them is not enough. Technologies would need to be integrated in the given system by both stakeholders and users. The approach of the multi-level perspective MLP provides a model to describe and analyse the comprehensive process of change as a socio-technical transformation, where the 'socio-technical regime' as a structure with its actors and their behaviour, thinking and interaction is being changed in interaction with innovation out of a 'socio-technical niche'. Push factors for this change arise from the 'socio-technical landscape', including trends or processes leading to pressure on a given system (Geels, 2002 & 2004; for mobility see also Geels and Kemp, 2012).

2.2. E-Mobility at Lake Constance Region

Within the framework of the project E-Destination e-mobility supply and infrastructure in the Lake Constance region were investigated. Related to system transformation and the model of the multi-level perspective the situation could be interpreted as a regional e-mobility niche. Thus, the potential and barriers for integration in the mobility regime shall be estimated based on this case study. The project focused on the examination of the existing interconnections between

[1] Corresponding author: merja.hoppe@zhaw.ch

various stakeholders and the potential for cooperation in order to promote electric mobility. The analysis was limited to electric mobility services, i.e. rental and sharing of electric cars and electric bikes and the charging infrastructure.
The area under investigation was defined as the Swiss cantons of Thurgau and Schaffhausen, the district of Constance and the Lake Constance district in Germany, as well as all other municipal areas in Austria, Germany and Switzerland that are located within a 10 km radius around the shore of Lake Constance. The analysis was based on secondary research, a standardized stakeholder survey and an expert workshop. Existing rental, sharing and charging infrastructure was recorded. Since the survey took place in June 2016, the infrastructure that is shown below is based on this state of data. The cooperation between the stakeholders was analysed by a standardized stakeholder survey conducted with 73 regional stakeholders from mobility, e-mobility, administration and tourism. In particular, they were asked about the current and potential cooperation between the stakeholders. In a concluding expert workshop, we were able to deduce measures and recommendations for promoting electric mobility in the region.

3. Results

While landscape pressure for todays' mobility system can be found in trends of increasing pressure to react on climate change, the need to reduce local emissions and to reduce resource consumption for mobility might lead to the development of different niche innovations. As the impact of different technologies and mobility concepts on the regime would lead to specific changes, any innovation would need to be analyzed solely. Although, certain barriers for change as well as supporting factors might be similar. Thus, the following analysis of e-mobility and rental/shared mobility in a niche for Lake Constance region as well as their potential for regime transformation provide some general insights on systemic transformation.

3.1. E-mobility in a Niche in the Lake Constance Region

The mobility system in the region – as elsewhere – is dominated by the regime of individual motorised transport based on internal combustion engines complemented by public transportation, cycling and walking. The niche of e-mobility in the field of rental, sharing and charging within Lake Constance region can be characterised as follows.
The region offers a variety of electric bike rental stations, predominantly at the shores of Lake Constance and in the bigger communities (Fig. 1). The market is very heterogeneous and characterized by many different operators. *Rent a Bike* is the only larger provider, though its operation area is limited to Switzerland. In Germany two providers offer more than one rental station, while the majority of the rental stations is operated by individual providers. In most cases the rental of electric bikes is not the main business activity of these companies. With the exception of *Rent A Bike*, cooperation between the various providers is lacking.
Sharing or hiring opportunities of electrically powered cars are very limited in the region with only two larger car sharing providers offering electric cars (*Stadtwerk am See with emma/Caruso*). In addition, eight rental stations are run by various providers, such as municipalities, companies and individuals. There was no connection identified between the operators of rental stations for electric cars and those for electric bikes.
The large number of electric bike rental stations indicates a niche for e-mobility in the region. The availability of electric cars for rent or sharing is still very low. In this regard the niche is just about to emerge. However, the niche seems to be already embedded in the mobility regime, due to the integration of the rental services of one of the two large providers *(Stadtwerk am See*) within the car sharing service of *Deutsche Bahn*, an important player within the German mobility system.

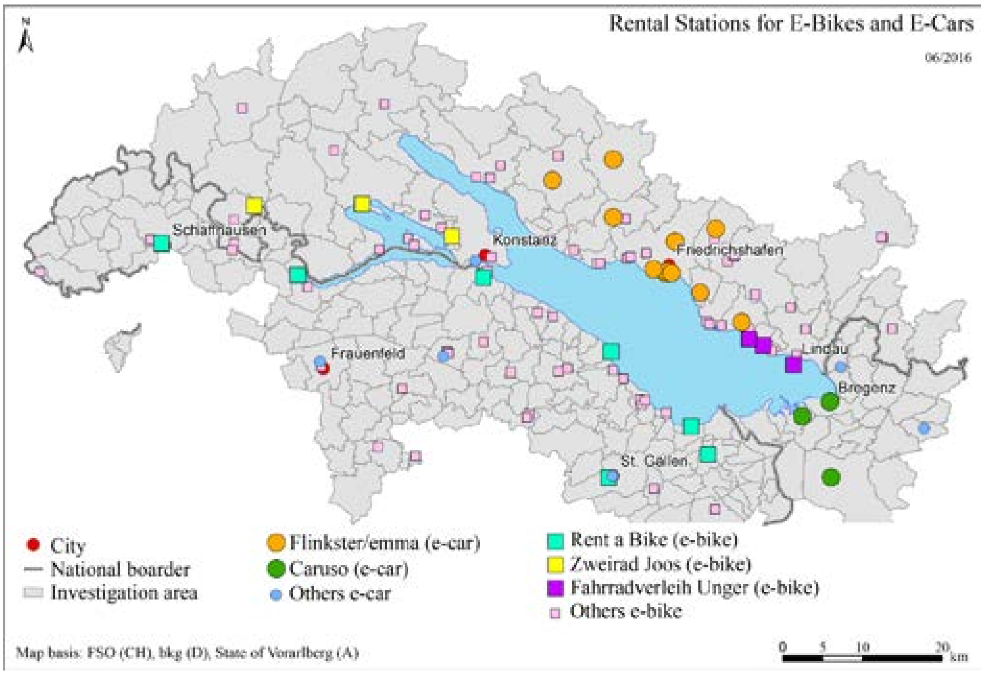

Fig. 1.
Rental Stations for E-Bikes and E-Cars

The charging infrastructure plays an important role in the establishment of e-mobility (Biresselioglu et al., 2018). Since e-bikes can be charged at any domestic power socket, the following results of the analysis refer to charging stations for electric cars. With around 300 recorded charging stations the density in the area is quite high, whereby the number of stations has grown since the investigation in 2016 (Chargemap, 2018). The stations are mainly located in cities, urban areas and in tourist destinations (Fig. 2). About 1/4 of these stations are domestic power outlets (SchuKo in Germany and Austria, SEV1011 T13 in Switzerland). Though these can in principle be used for charging electric cars, they are not designed for a permanent load with the usual maximum amperage and are therefore not suitable for long-term usage (e-Stations, 2016). However, from supply side the market is very fragmented. There are 18 players that operate more than one station and/or act regionally, nationally or internationally. These provide about half of the stations, the remaining stations are run by individual operators. Most of the providers of charging stations have limited market areas. Furthermore, with the exception of the Austrian *Vorarlberger Kraftwerke* no operator is active across borders. In the German and Austrian investigation area, the market areas are rather regionally limited. In Switzerland, on the other hand, several operators act nationally (e.g. *EVITE*, *MOVE*, *easy4you* and *swisscharge*).

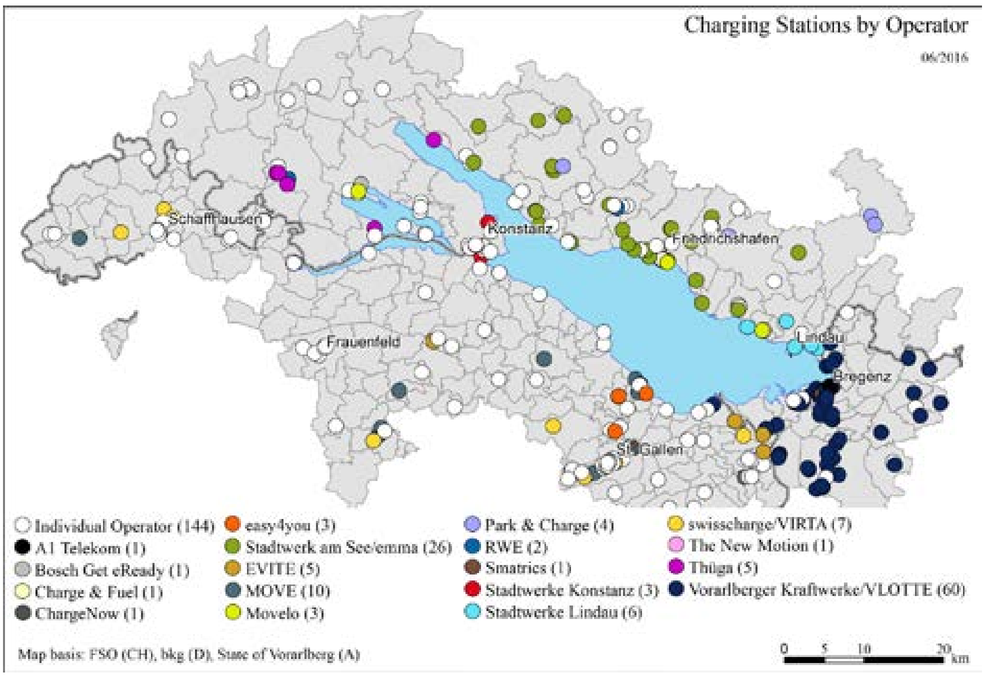

Fig.2.
Charging Stations by Operator

The problem arising with the large number of providers is that each of them uses its own access system for customers to use the charging stations. Depending on the provider, access and payment are carried out via RFID card, QR code, app, EC card, Credit Card etc. This diversity poses a barrier to the use and thus the establishment of electric mobility. Consequently, cooperation between charging station operators is of particular importance - e.g. by roaming agreements allowing the customers of a specific provider to use the stations of others. Figures 3 and 4 show the interconnection between charging station operators by country. The large dots represent "charging networks" including operators of charging stations as well as companies only integrating charging stations from operators and making them available to their customers. The small dots are charging stations and the connections between the dots show which charging network allows their customers to charge at which charging station.

The density of cooperation varies greatly between the three countries. The German part of the area is characterized by little cooperation between the operators, except for *Intercharge* and *Plugsurfing,* with many stations not integrated into a charging network. The situation in Austria is different: the market is dominated by one utility company *Vorarlberger Kraftwerke,* which is also very well connected to many other charging networks. In Switzerland, on the other hand, numerous charging stations are not part of a charging network. Similarly, there is hardly any collaboration between these charging networks - with the exception of two companies (*Intercharge* and *The New Motion*) having roaming agreements with other providers.

From the multi-level perspective on systemic change e-mobility developed in a niche within the Lake Constance region so far leading to a variety of players on the market, which is increasing complexity for users and thus preventing a development out of the niche for both, e-mobility and rental/shared mobility.

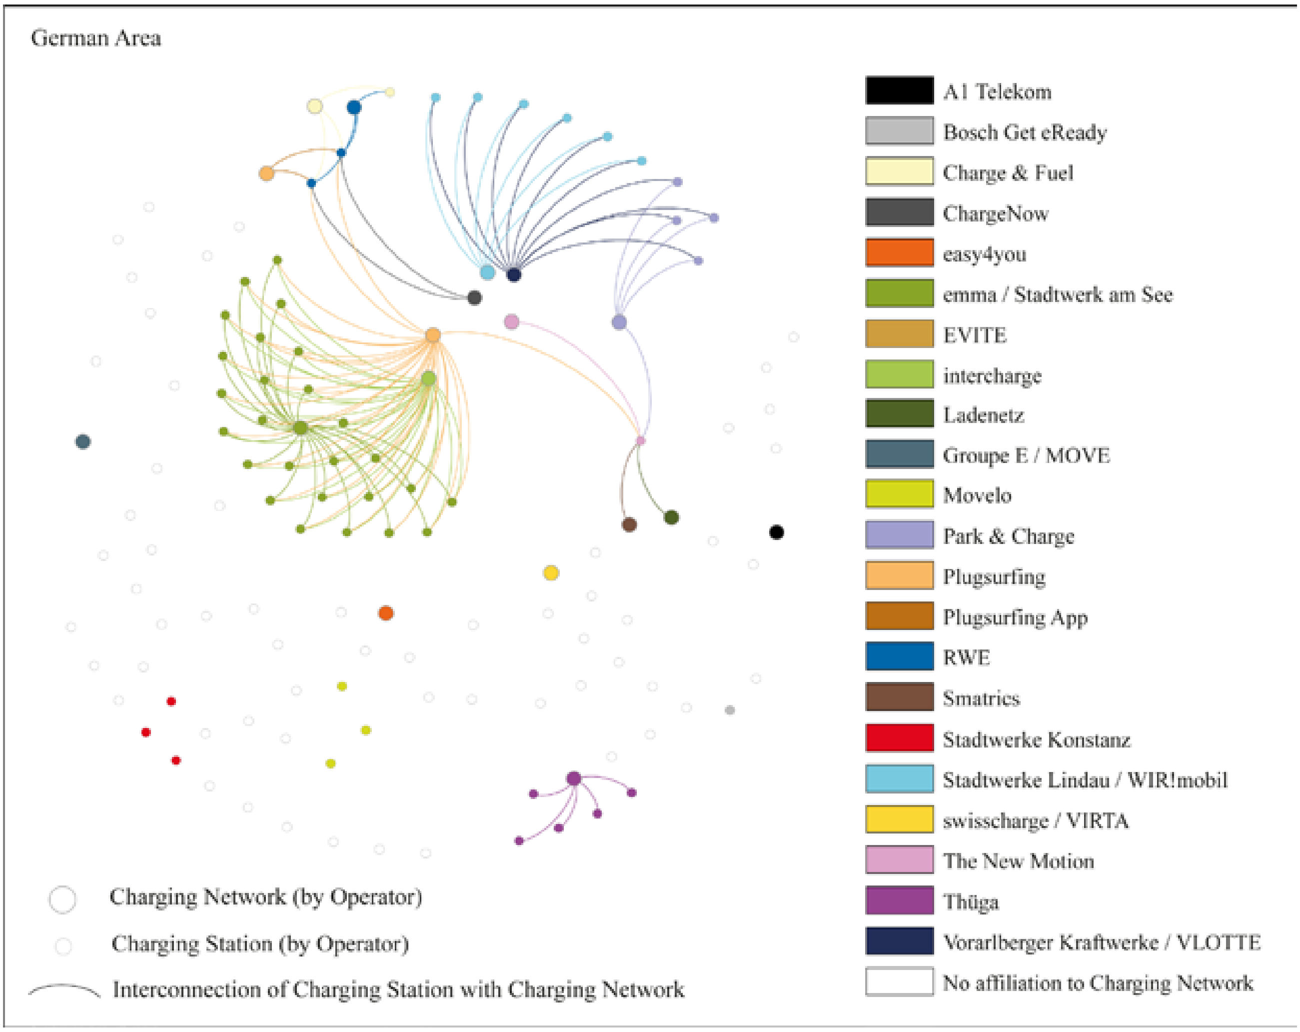

Fig. 3.
Interconnection between Charging Networks by Country, German Area

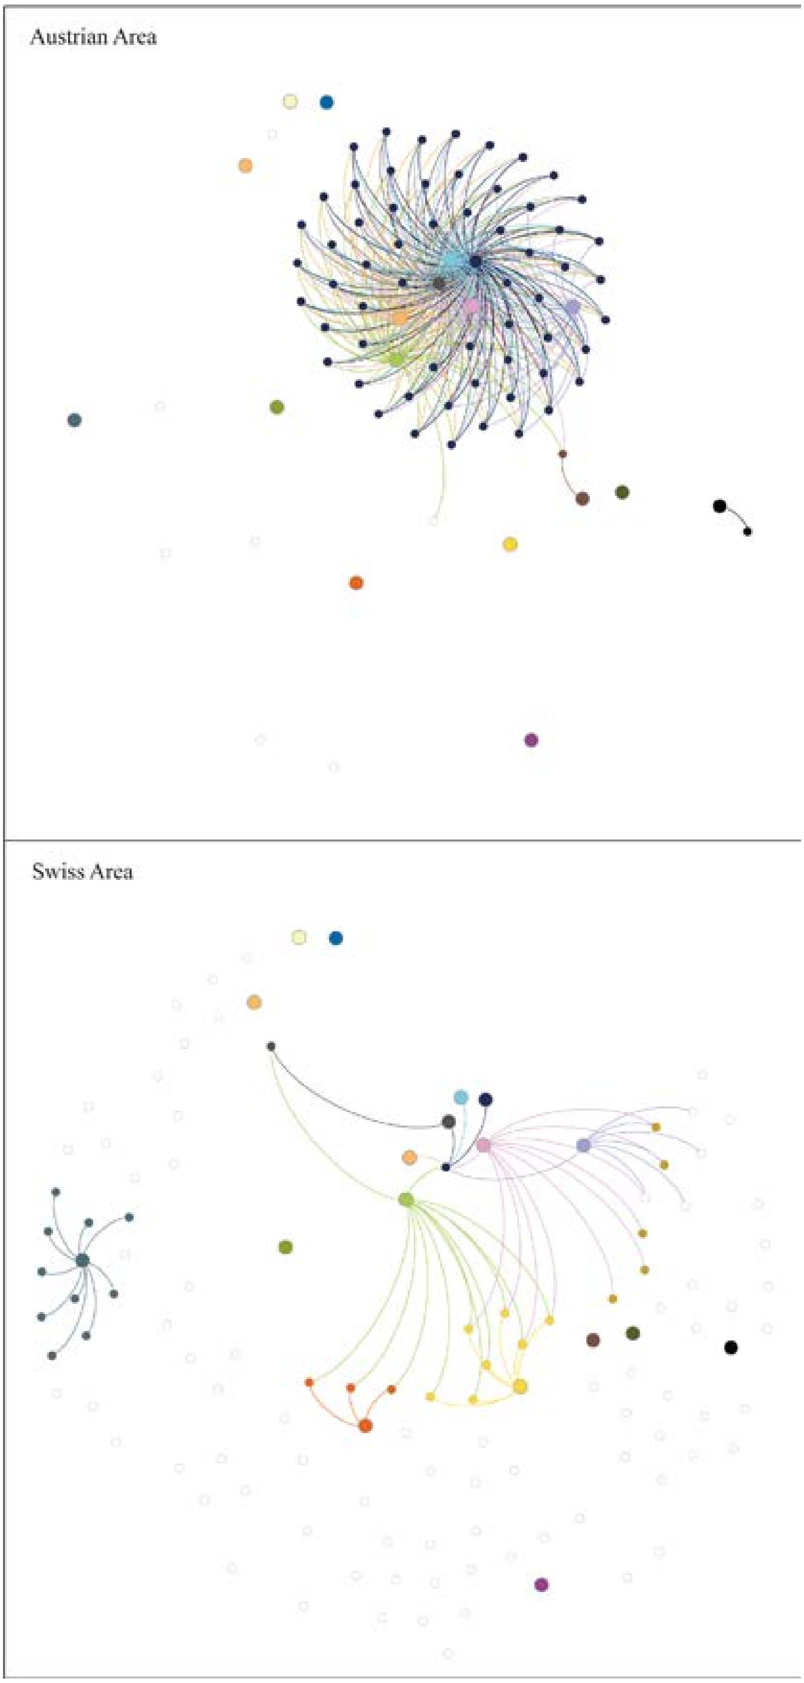

Fig. 4.
Interconnection between Charging Networks by Country, Austrian and Swiss Area

3.2. Potential of System Transformation at Regime Level Trough Cooperation

The analysis reveals the existence of an e-mobility niche in the region. However, system transformation at the regime level has not yet taken place. Lacking cooperation between the actors and low integration of services on the supply side have been identified as significant reasons. The stakeholder survey not only confirms the importance of more cooperation for the expansion of electric mobility but reflects stakeholders awareness about the topic. When asked about the importance of different aspects for the spread of electric mobility, stakeholders evaluate those aspects related to cooperation and greater networking throughout as more important than the further development of the charging and rental infrastructure.

One form of cooperation could be realised by joint mobility offers that integrate electric vehicle renting with existing mobility services such as public transportation. By this means, longer distances could be covered by public transport and the last mile by e-mobile vehicles. Such solutions could not only promote the use of public transport, but also reduce individual motorised transport and thus enhance system transformation at the regime level towards sustainable mobility. On the Swiss side such an intermodal service already exists with the cooperation of the (e-)bike rental company *Rent a Bike* with the Swiss Federal Railways, various private railways and other partners. However, there is a lack of such collaborations in the German and Austrian parts of the region. The stakeholder survey and discussions with industry representatives show limited interest in such collaborations, both from the side of public transport providers and rental companies. This is due to the fact, that the rental of e-bikes is usually not part of the core business of the rental companies. Another reason is the large number of providers, which makes it much more difficult to establish such collaborations.

In this context, greater cooperation between providers of electric vehicles would be even more important. Nevertheless, the stakeholder survey shows that the interviewed rental and sharing companies have a limited interest in a stronger cooperation with other rental or sharing operators. Only one of the participating 14 rental and sharing companies is interested in greater cooperation in the fields of "shared mobility services" and "booking and payment". Two of the respondents would like greater cooperation in the area of "advertising and communication". The rental and sharing companies are much more interested in cooperating with partners from tourism and charging station operators, especially regarding communication and advertising, but also in terms of joint mobility services.

As described in 3.1., cooperation among charging station operators is greater than among the rental and sharing companies of electric vehicles. However, there is still potential for greater collaboration, especially in Switzerland and Germany and on an international basis. In many cases, one reason for the lack of networking is due to the business models of the charging station operators. Most of the providers are regional (public) utility companies that offer the charging infrastructure for their customers and have no ambitions to operate beyond their regional market or internationally, with few exceptions. As a result, the supply side seems fragmented making it difficult for users to gain overview and access e-mobility, sharing/rental and charging opportunities; it is not a surprise that there is no market uptake of electric mobility technology and rental/sharing.

Some operators, which do not operate their own stations but base their business model on the connection and integration of the existing charging stations of other operators may help to solve the problem. These integrators (e.g. *Intercharge* and *Plugsurfing*) enable a barrier-free use of the charging infrastructure and thus of electric mobility; they serve as drivers for a system transformation at the regime level. At the same time, it is also noticeable that an increasing number of energy supply companies are discovering electric mobility as a new business area, thus also opening up opportunities for system transformation. Concerning the regime level, it can be concluded that one of the barriers for cooperation and coordination to a better integration of services is that some companies do not operate as part of the mobility system. If charging or mobility services are offered as an add-on to other businesses there is less interest of contributing to a better organized mobility system. Changing a regime means building a new regime – with all relevant stakeholders included; in this case alliances still have to be formed as well as ways of organizing the use of the new infrastructure and of cooperating to offer it to the users have to be set up.

3.3. Supportive Interventions and Measures

The analysis shows that there is a niche for e-mobility in the fields of rental/sharing and charging in the Lake Constance region and that it is gaining stability. In particular, the infrastructure is available and is being further expanded. However, in order to take the next step towards the integration into the recent mobility regime, there is a need for organization and collaboration within the niche, as well as with the existing regime. Obstacles for cooperation result from the large number of providers, their unwillingness to collaborate and the fact that cooperation in the region is constrained by national borders and corresponding legislation. These circumstances make a bottom-up transformation more difficult.

A common vision and strategy for e-mobility could help as a central element of a future development of e-mobility in the Lake Constance region. For instance, this could take place under the auspices of regional organisations (e.g. *Internationale Bodenseekonferenz, IBK*). The IBK is a cooperative association of the states and cantons around Lake Constance. It is a platform of governments and administrations for common topics regarding education, research, economy, environment and social affairs (IBK, 2018). Such a vision and strategy could, for example, be integrated into the IBK mission statement “Leitbild Bodensee 2030” and thus provide a framework for future regional and national decisions. An e-mobility strategy could promote different measures. An important step would be to bring the various actors together and facilitate an ongoing dialogue. An important field of action involves the promotion of joint mobility solutions such as the integration of public transport and e-mobility rental services. In this respect, the aim should be to collaborate with existing services, e.g. with mobility and tourism packages (e.g. *Bodenseeticket* or *Bodensee Erlebniskarte*). Another way of promoting cooperation between the various mobility services would be a coordinated creation of connected mobility hubs, for example at railway stations, tourist attractions or other important junctions. A

further aspect is the creation of a common data platform to ensure the communication of the various services - based on existing platforms and data sources instead of setting up new ones.
With regard to infrastructure, experts do not see a need to support a further expansion of the rental and charging infrastructure for e-bikes. In the case of rental, there is already a market sufficiently regulated by supply and demand; an expansion of the charging infrastructure for e-bikes is technically not required and is not profitable. Nevertheless, there are still no e-bike sharing systems in the region, the development of which could certainly be encouraged by the municipalities. In addition, the promotion of the increased use of electric cars should be considered. One possibility could be opening up commercial vehicle fleets to e-car sharing systems, whereby many organisational obstacles would have to be overcome. Furthermore, on the technical level standards and uniform modalities for the use of charging stations are necessary.

4. Conclusion

The analysis of the situation of e-mobility in terms of infrastructure, rental/sharing, stakeholders and cooperation showed that electric mobility has been developed within a technological niche in the Lake Constance region so far. Barriers, challenges and starting points to push the transformation of todays' mobility regime towards e-mobility have been identified.
While distribution of charging infrastructure within the region is good, supply side is suffering from fragmentation of technical standards, information about and accessibility of locations for charging and renting/sharing. Cooperation on the supply side as well as connectivity to the existing (public) transport system is underdeveloped. This situation leads to a lack of information for customers and to disorientation concerning available mobility services from the users' perspective preventing them to change their mobility mode. In order to support regional distribution of e-mobility, market uptake of the technology and new mobility concepts like renting/sharing – leading to a new mobility regime in the end – more coordination and cooperation is necessary. The case study also showed that technical, informational and organizational borders replace political and administrative ones. Thus, cooperation and coordination would need to be supported within this fields aiming to provide overall information and accessibility for users.
The results are not only relevant for the case study Lake Constance but serve as an example for barriers and challenges other regions, new technologies and mobility concepts have to face. Identifying relevant stakeholders, fields of cooperation and supply-demand fit are good starting points in order to support a regime change in mobility.

EMERGING TRENDS IN TRANSPORT TECHNOLOGIES: THE POTENTIAL FOR TRANSFORMATION TOWARDS SUSTAINABLE MOBILITY

Merja Hoppe[1], **Thomas Trachsel**[2]
[1, 2] Zurich, University of Applied Sciences, Technikumstrasse 9, 8400 Winterthur, Switzerland

Abstract: The global increase of CO_2 emissions requires a transformation of the transport system. This paper aims to provide an overview of emerging cutting-edge transport technologies and mobility services that may have the potential to enable a transformation of the transport system towards sustainability. Thus, innovative transport technologies and mobility services were identified, focussing on non-scientific literature to keep track on the latest developments. The future trends for four technology categories of vehicles, engines, materials and infrastructure/operating technologies were assessed concerning their potential for supporting a change of the mobility system towards sustainability. Based on this, gaps and blind spots in current transport research activities were revealed. Especially autonomous driving systems appeared as emerging trends in all modes of transport. Several prototypes of unmanned cargo ships and aircrafts are currently in trial operations and indicate a large-scale implementation of the technology first in the freight sector. The major breakthrough though is expected in passenger transportation, where besides prototypes of autonomous vehicles several other innovations such as autonomous passenger drones already exist. Results further indicate a trend towards new business models and mobility services (e.g. Mobility as a service or on-demand systems) as several cities already announced to ban cars from their urban centres through implementation of these new mobility solutions. Related to these developments, new stakeholders will enter the mobility market and realign the initial competitors' landscape. Finally, technological developments as part of the emerging Industry 4.0 (e.g. additive manufacturing) will significantly influence traditional manufacturing processes and lead to a fundamental reorganisation of the transport industry in the future. Results of the trend analysis show that many new mobility options are arising from innovation, providing the potential for system transformation towards sustainable transport and mobility. However, this potential will only be realized if guided into the right directions by stakeholders, regulation and society as the study further revealed that innovations imply the danger of accentuating today's problems. Thus, a focus on mobility paradigms, sufficiency principles and strategies in both transport research and policies are of crucial interest.

Keywords: Trends in transport technologies, system transformation, sustainable mobility.

1. Introduction

Climate change, and in particular its adverse effects on large parts of our society, is one of the major challenges facing humanity in the coming decades. One of the main contributors to climate change is the transport sector, which features with 27.9% the highest growth rates of CO_2 emissions in the European Union compared to any other industrial sector (EEA, 2016). This goes back to the development of the combustion engine, which - in combination with the growing prosperity in industrialized countries and a lack of covering the external costs of mobility - made individual motorized mobility accessible and popular to a broad public. Besides the increasing CO_2 emissions, congested roads, safety issues and an increasing loss of cultural landscape by expanding transport infrastructures are just a few of many other negative impacts. A transformation of the transport system towards sustainability is necessary to address these challenges as well as to ensure innovation, efficiency and long-term competitiveness of the transport sector in the future.

In this regard, technological progress is often seen as a panacea. However, some emerging technological innovations in the transport sector "at first glance" seem to be clean and sustainable but raise severe questions and doubts with regard to their overall eco balance. The aim of this paper is therefore to provide an overview of cutting-edge transport technologies and mobility services that are currently emerging and that may have the potential to enable a transformation of the transport system towards sustainability.

2. Methodology

As a starting point for the literature review underlying this work, a **model of a transport system** has been applied. The model was developed in the initial stage of the *Swiss Competence Center for Energy Research - Efficient Technologies and Systems for Mobility (SCCER Mobility)* research project. The main objective of *SCCER* is to develop the knowledge and technologies essential for a transition from the current fossil fuel based transportation system to a sustainable one, including minimal CO_2 output, primary energy demand as well as virtually zero-pollutant emissions (SCCER Mobility, 2018). As a theoretical foundation, the model draws on the multi-level perspective (MLP) introduced by Geels (2002), a framework to explain systemic transformation processes.

The structure of the model was elaborated through questioning experts from the transport sector on their perception of the mobility system and its constituents. This resulted in a systemic delineation of mobility that addresses the 'mobility system' through its holistic nature with mobility related aspects, drivers and transport-related fields. In addition, it provides a framework, to understand past and current developments in the different fields of the system, as well as to project possible pathways for a future transformation of the system. The model consists of six thematic fields: (1) Technology / R&D, (2) Policy, (3) Economy, (4) Society, (5) Transport sector and (6) Spatial order. Each of the six thematic fields consist in addition of various components that interact with each other or have an interrelationship. This

[2] Corresponding author: trah@zhaw.ch

results in a total of 14 components, which further subdivide the main thematic fields of the systemic model (Hoppe and Michl, 2018).
For the specific purpose of the present research project, the model of the transport system has been reduced to those system elements that are expected to play a major role in future transportation and that are reflecting promising research areas, especially with regard to a transformation of the system towards sustainability.

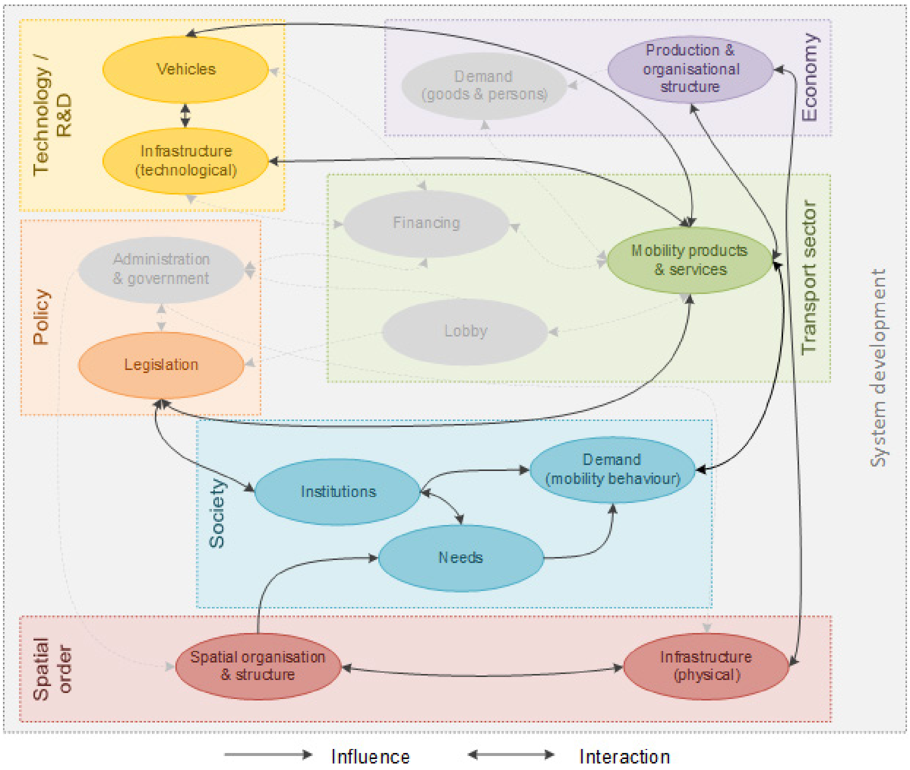

Fig. 1.
Model of the transport system
Source: Hoppe and Michl (2018)

According to this framework model of the transport system, current trends and developments in the mobility system were identified systematically in a broad-based **literature review**, collecting information from project reports, trend studies, transportation websites, future-oriented blogs, news reports and journal articles. Thereby the focus lied deliberately on non-scientific sources, to capture the latest trends in the various fields of research. In a final step, each identified trend was assigned to the corresponding system element within the underlying systemic framework model. This resulted in a detailed and extensive description of emerging trends and developments in the transport system, having the potential to significantly influence the current system and lead to a transformation in the future.

3. Large Scale Trends in Transport Technologies

The transport sector is currently changing through several emerging technological innovations. Some of these trend-technologies were newly developed; other technologies have existed for several years already, not able to exceed their current state as a niche technology yet. Aside from their current state of diffusion, the majority of today's trend studies assigns new technological developments a key role in the transformation process of the transport system. Whether it is about the reduction of CO_2 emissions through optimization of combustion engines, the electrification of propulsion systems or the development of new battery technologies, all these developments and forecasted trends have a major potential to change the mobility system towards sustainability in the future.

3.1. Trends in Vehicle Technologies

In the field of vehicle technologies, **autonomous driving systems** are one of the major trends emerging on a large scale. Over the past decades, cars have been equipped with all kinds of driving assistance systems like cruise control, collision warning and lane-keeping support and are gradually approaching full autonomy. Autonomous vehicles offer a great potential to change people's initial way of thinking about cars, resulting in a new perspective on mobility where commuters, for instance, make better use of time by preparing for work while travelling from A to B (Rauch, 2017). In addition, autonomous vehicles may provide greater safety, reduce emissions and increase road capacity through optimized traffic flows (Davies, 2016). Although an integration into the transport system would already be technically feasible, non-technical issues (e.g. consumer confidence and legal aspects) as well as difficulties involved in controlling a vehicle in unpredictable and challenging traffic conditions are some of the major constraints the transport industry is currently facing (Delle Site et al., 2012). Wadud et al. (2016) estimate a complete integration of autonomous vehicles into the transport system not before 2030.

Besides the automotive industry, the trend of autonomous driving systems is also taking place in the other modes of transport. In the **maritime industry**, northern European countries take a pioneering role in the transformation process towards autonomous shipping by aspiring to implement autonomous cargo vessels on coastal routes by 2019 (Birger, 2017). In the **aeronautical sector**, the two major global players *Boeing* and *Airbus* are both testing autonomous systems. While *Boeing* is pursuing concrete plans for autonomous aircrafts, its competitor *Airbus* is focusing on a concept of a self-driving vehicle that can be converted into a drone (Futurezone, 2017). In October 2017, the Chinese aircraft manufacturer *Longxing UAV Systems* performed a successful maiden flight of an unmanned cargo aerial vehicle that operates in both, autonomous and remote pilot modes and is particularly suitable for cargo operation in remote areas (Aerospace Technology, 2017). Ultimately, autonomous systems are also being tested in the **railway industry**. While there already exist a few prototypes for passenger transportation, the industry's focus lies mainly on autonomous systems for shunting and cargo operations. An Australian mining company, for example, runs the world's first fully autonomous freight train in operation since 2017 (Leary, 2017).

Another major trend in vehicle technologies are **drones**. Formerly mainly used in the military sector, drones are nowadays increasingly being tested in private and commercial applications. According to Dobie et al. (2016), 600'000 drones are currently in commercial use in the United States and about 1.9 million in private ownership and by 2020 these values are even expected to triple. Although numerous logistics companies are testing drones for goods and distribution logistics, legal framework conditions for regular commercial operations are still insufficiently worked out (Amazon, 2017). In addition, there are also several concepts for passenger transportation emerging. In 2016, the Chinese drone manufacturer *Ehang* presented its concept of a single-seater aircraft that claims to be the first of its kind to transport passengers autonomously (Cavanagh, 2017). First successful tests of this autonomous passenger drone have been carried out in Dubai in 2017. However, a mass production is not yet foreseeable and drones for passenger transportation remain a niche technology for now (Schmid, 2017).

3.2. Trends in Engine Technologies

In the field of engine technologies, one of the major trends currently influencing the industry is the **electrification** of conventional drivetrains. Already affordable middle class electric cars reach nowadays 300 kilometers and more with one single battery charge and the trend continues to improve (Cobb, 2016). However, there remain several constraints concerning the overall eco-balance of electric vehicles. According to Romare and Dahllöf (2017), the production of one single *Tesla* battery causes about 17.5 tons of CO_2. This equals emissions of about 150 to 200 kilograms CO_2 per kWh battery capacity. In addition, global production of cobalt and lithium would have to increase between twenty and thirty times to the present level to ensure a complete switch from conventional to electric drivetrains (DWN, 2017). Nevertheless, market shares of electric vehicles are constantly growing and are predicted to account for 25 to 40% of new vehicle registrations worldwide by 2030 (Arzt, 2017).

Besides the automotive industry, the trend of electrification is also taking place in the other modes of transport. In the **maritime industry**, Scandinavian countries again play a leading role in the transformation process towards electric drivetrains in Europe. A number of electric ferries are already in operation on local connections and several orders for new electric ferries have been placed recently (Feusi, 2017). In the **aviation industry**, a growing number of aviation companies are investigating the potential of hybrid-electric propulsion technologies. A cooperation between *Airbus*, *Rolls-Royce* and *Siemens* recently announced a maiden flight of a hybrid-electric aircraft by 2020 with the primary goal to provide a commercially viable hybrid passenger jet for regional air services by 2030 (Hollinger, 2017). Finally - against the common belief - electrification of drivetrains is still an important issue with regard to sustainable **rail transportation**. In Germany for example, only about 59% of all railroads are electrified and diesel-powered locomotives are still widely used, especially on peripheral railroads. Various research projects are therefore focusing on clean fuel technologies. However, the costs of an additional supply infrastructure as well as the conversion of the existing drive technologies are currently the biggest challenges (BMVI, 2017).

A further trend that is anticipated to take on major influence in the development of sustainable engine technologies is the **hydrogen fuel cell** technology. Although hydrogen propulsion shows a vehicle-side efficiency from around 45%, the production of hydrogen itself is still very energy-intensive. The International Energy Agency (IEA) estimates a fuel cell vehicle (FCV) market share of about 17% by 2050 with 35 million annual unit sales (Arena et al., 2017). Further trend studies estimate that hydrogen fuel cell technology could become the fastest growing propulsion technology in the automotive market by 2050 (Jaffery, 2016).

3.3. Trends in Material Technologies

In the field of material technologies, **additive manufacturing** is one of the major trends emerging on a large scale. Formerly mainly used for the production of prototypes, 3D printing is becoming increasingly important for industrial mass production of individual components in the course of the emerging Industry 4.0 (Richter and Wischmann, 2016). According to Wood (2016), 3D printing technology could substantially disrupt conventional manufacturing practices by offering modular production alternatives, onsite manufacturing, and the ability to create parts, tools and even complete

vehicles on-demand. In 2015, the world's first car - at least in parts - was produced using additive manufacturing technology (Schroeder, 2015).
Besides the automotive industry, 3D printing is also attracting more and more attention in the other modes of transport. In the **aerospace industry** for example, the world's most important manufacturer of aircraft engines, *GE Aviation*, uses already today more than 300 3D printers in its factories and aims to produce by 2020 about 100'000 additive parts per year (GE Reports Staff, 2017). In the European **railway industry**, the *Deutsche Bahn (DB)* - the largest railway operator in Europe – produces annually about 1'000 spare parts using 3D printers and in the future the company plans to extend its production capacity up to 15'000 spare parts per year (Global Rail News, 2017). Finally, in the **maritime industry**, Britain's royal navy plans to use 3D printed unmanned ships by 2030 (Hedstrom, 2015).
Another technology trend that is gaining increasing popularity in combination with 3D printing is **lightweight construction**. The main objective of lightweight construction in the transport industry is to save raw materials and energy due to lower vehicle weights (IAI, 2016). There have already been several concepts for lightweight vehicles emerging in recent years. In December 2017, the Swedish start-up *Uniti* presented a lightweight electric vehicle (about half a ton), which is specially designed for commuting in urban areas. Series production is scheduled for 2019 and with *Siemens* as one of the main partners, a fully automated version of the vehicle is expected to enter the automotive market in the near future (Schäfer, 2017).
Similar goals to those of lightweight construction - especially with regard to energy optimization - are pursued with **aerodynamic optimization**. The main objective of aerodynamic optimization is to design the form of vehicles and infrastructures (e.g. tunnels) in such a way that air resistance and consequently the energy required for locomotion declines. The *German Aerospace Center (DLR)* is investigating in this field of research with planning and construction of the *Next-Generation-Train* (DLR, 2013). Other examples of aerodynamic improvements are to be found in the Japanese high-speed train *Shinkansen* (Railway Technology, 2017) or the *Hyperloop One*, in which a transport capsule moves in an air-evacuated tube with considerably lower air resistance than conventional trains (Bradley, 2016).

3.4. Trends in Infrastructure and Operating Technologies

In the course of digitization and the advancing Smart City movement, **Intelligent Transport Systems (ITS)** are rapidly emerging. ITS-technologies optimize traffic flows and the use of infrastructure by intelligently managing and directing the different traffic elements. According to Kantowitz and Le-Blanc (2006), the following three types of communication can be differentiated within ITS-technologies: Vehicle-to-Infrastructure (V2I), Infrastructure-to-Vehicle (I2V) and Vehicle-to-Vehicle (V2V). Practical applications for V2I and I2V technologies can be found in car park management, traffic management, usage-based cost accounting or navigation applications. V2V communication technologies (e.g. adaptive cruise control, lane departure assistance or active brake assistance) have become widespread standard in all newer vehicle models, mainly due to the current developments in the automotive industry towards (partly) autonomous driving. V2V communication comprises a wireless network where vehicles send messages to each other with information about what they are doing right now. This data includes for example speed, location and direction of travel, which can be further processed - using complex algorithms - to alert drivers about hazardous situations ahead (Howard, 2014).
A further emerging trend in V2V technology is **Truck Platooning**, where trucks are connected with each other in such a way that they automatically move one after the other at a constant distance. This intends to relieve the drivers and save fuel by using slipstreams at reduced vehicle distances. Furthermore, Truck Platooning is also expected to induce road safety improvements. While a human driver has a reaction time of about 1 to 2 seconds, V2V communication can reduce the response time up to 0.2 seconds according to a study of the German vehicle manufacturer *Daimler* (Wilkens, 2017). After a successful multi-day test drive with six different truck manufacturers participating in 2016, Truck Platooning could be technically applicable in Europe by 2020 (Wilkens, 2016).
A final technology that needs to be mentioned in the context of V2V-technologies is the development of **swarm/collective intelligence**, which includes by definition that specific actions of individuals can evoke intelligent behaviours in the community through communication and networking activities (Dambeck, 2011). An example of an application relevant to mobility is the concept of community-based parking, which has been introduced by the German *Bosch Group* in 2016. The concept intends that a large number of vehicles participate simultaneously in the search of free parking spaces scattered throughout a city, thus making it much easier for the community to locate a free space than if each car had to search on its own. Once a "transmitter vehicle" detects a free parking space, this data is transmitted to a cloud where it is further aggregated and processed into a digital parking card. Based on this data, the "recipient vehicles" receive a precise indication, where free parking spaces are currently available (Greis, 2016).

3.5. Emerging New Mobility Products and Services

In the course of digitization and following the previously described technological developments, several **new mobility products and services** have emerged in recent years. According to Rauch (2017), digital networking does not only provide for more mobility offers. It creates rather a completely new layer on the mobility structures and the exchange of data between road users, vehicles and the surrounding infrastructure achieves the next level of mobility: a self-controlling system of real-time traffic planning, on-demand availability and smooth transitions from one mode of transport to another. According to a study of *Frost & Sullivan*, more than 20 million vehicles could be removed

annually on urban roads as a result of a further growth in new mobility services (ride-sharing, ride-on-demand services, etc.) as from 2025 (Briggs and Sundaram, 2016).
A major trend in the field of new mobility products and services are **sharing systems**, which originate from a fundamental rethinking in the ownership of mobility products, turning from ownership of transport modes to the use of transport modes (Delle Site et al., 2012). Especially in mature economies societies, a shift towards shared economies is currently evolving. However, this tendency is more evident for younger generations (Generation Y) and car ownership in general is highly affected by new attitudes and behaviors (Corwin et al., 2016).
Another important trend is a growing range of **mobility as a service (MaaS)** products evolving. MaaS organizes the entire transport chain for the mobility users, including planning, booking and accounting of trips in a mostly smartphone based system through all modes of transport. Several MaaS projects have emerged recently in Europe. The city of Helsinki for example has announced its intention to eliminate the need for privately owned cars by 2020 through the implementation of MaaS (Franckx, 2015).
A final trend in the field of new mobility products and services are **on-demand services** that are ordered individually and on-demand by the consumers. In particular, road-based services have established themselves recently on a large scale so far and further research is being intensified to achieve a complete autonomous operation of these systems (Dvorsky, 2017). As an example, the German car manufacturer *Volkswagen* presented its on-demand concept of a fully electric ride-pooling service called *MOIA* in 2017. Core of this concept is an electric vehicle with a capacity for six passengers that has been designed specifically for ride-pooling services in cities. Besides the vehicle, the concept also consists of a customer app, enabling passengers to book and pay for the ride on a smartphone based system. The main objective of this new mobility service uttered from the operator is to remove one million cars from the roads of major cities in Europe and the United States by 2025. In 2018, the service will be first launched in the city of Hamburg (Intelligent Transport, 2017).

4. System Transformation Towards Sustainability?

Besides effects of the single technologies on the transport system, general developments with their likely impacts on sustainability can be identified based on the trend overview:

1. Related to the **transport system** almost all new technologies and services create and require higher interconnectivity in terms of data and information exchange on different levels: Within vehicles, between vehicles and different modes, between vehicles and infrastructure as well as to transport system users. As a result, the transport system becomes more complex concerning data handling and system control on one side – allowing to optimizing the system in terms of resource consumption, energy efficiency and emissions on the other side.
2. On the **transport market**, the diversity of innovative solutions and new players is leading to higher complexity in the area of communication, coordination and use of new services and technologies. The transport market is about to be reorganized in terms of stakeholders, rules and supply-demand relations, which requires adaption to new frame conditions from both supply and demand side. This variety would allow for supporting the best solutions in terms of sustainability, in an ecological, social and economic sense.
3. As the implementation of technologies and services depends on user acceptance, **social and economic developments** are deciding factors for the direction of future development in transport. Innovation would only lead to fundamental change if they initiate a process of socio-technical development. In the past new options in mobility (as elsewhere) have promoted use of them and thus increased demand with the familiar effects of rebound in resource consumption and total of emissions in transport. Even if the potential of the described innovations contribute to sustainable mobility, the danger of reverse effects is high.
4. Regulation and **transport policies** will be crucial in this context setting the frame for implementation of technologies, success of related mobility services and the overall development of the transport system – especially when it comes to sustainability. Strategies of enabling what is possible would lead to increase of mobility options with strong rebound effects (as in the past), while transport policies aligned with European climate goals in combination with the described innovations have the power to push for a systemic transformation towards sustainable transport.

To conclude, results of the trend analysis reveal that innovation in technology and mobility services have the potential for both fundamental change of the transport system and a push for sustainable mobility. On the other side, they come with high uncertainty bearing the danger of negative side effects of the developments. As crucial factors within this context, decision making of stakeholders and users will play a major role and thus would need to be considered. Social and technological system development in interconnectivity will decide upon the future direction in terms of sustainability, which needs to be taken into account from a very early stage of innovation development.

5. Conclusion

The main objective of this paper is to provide an overview of cutting-edge transport technologies and mobility services concerning their potential to enable a transformation of the current transport system towards sustainability. In the field of transport technologies, results indicate that autonomous vehicles can be expected to have a strong disruptive effect on the transportation system and the current mobility behavior patterns and could lead to a substantial rethinking of established business and ownership models in the future. In addition, the expected increase in efficiency in traffic flows and a possible reduction in the number of vehicles through autonomous on-demand services could have a significant impact on the sustainability of the transport system in the future. However, it remains unclear how fast the technology will be able to establish in passenger transportation. Systemic effects of autonomous driving as well as of other technologies or services like MaaS will strongly depend on (political) frame conditions, user acceptance and transport market development.

When it comes to sustainability in transport, results concerning the likely future developments in transport reveal gaps in both perspective of research and policies. A variety of new mobility options are arising from innovation, providing the potential for system transformation towards sustainable transport and mobility. This potential would need to be guided into the right directions by stakeholders, regulation and society as innovations also imply the danger of accentuating today's problems by increasing demand of mobility with its side effects. Thus, a focus on new mobility paradigms, sufficiency principles and strategies in both transport research and policies are of crucial interest.

Within this context, the next step in the underlying research project will be to conduct qualitative interviews with experts from the transport sector. This will serve as a basis to formulate hypotheses concerning the evolutionary development of the transport system with a special focus on the aforementioned new paradigms, principles and strategies. The hypotheses will be validated in a subsequent online survey to ultimately identify gaps and blind spots in transport research.

POLITICAL IMPERATIVES IN TRANSPORT A LONG-TERM VISION FOR THE DECISION MAKING PROCESS

Norman Döge[1], Massimo Moraglio[2], Johanna Ostendorf[3]
[1,2,3] Technische Universität Berlin, Germany

Abstract: This paper illustrates the findings regarding Political Imperatives, those influencing the future of the European transport sector. The identification of the European Political Imperatives in the transport sector is guided by the influence they can have in being 'game-changers' for the whole sector. This has led to analysis of 130+ Political Imperatives as produced both within and out of Europe, focusing on the different actors developing those Imperatives. Based on frequency and relevance, the report lists circa 60+ claims/demands and an equal number of Intentions as suggested by those Political Imperatives. As a final outcome, a comparison of formulated demands/ claims to and identified notices of intentions by the political sphere allows to identify those imperatives that are not yet part of the political agendas but might gain importance in the future. The core analysis shows which political imperatives are currently dominating the discourse and are thus important starting points for creating an image of the future transport sector. Imperatives that are amongst other aspects directly or indirectly having the goals of reducing GHG emissions by supporting modal shift, substituting the source of energy (EV's, alternative fuels) or using existing infrastructure more efficiently are making up the majority. Forward looking imperatives are especially touching urban transport and data issues. Here it can be stated that the imperatives coming from the European stakeholders were much more forward looking and that topics like intelligent transport systems, MaaS, green logistics have – although quite weak – already found entrance into some strategy papers. The deliverable has created an initial snapshot of the current state of imperatives with relation to the transport sector. However, it has to be expressed that a deeper and especially longer lasting assessment of the international sphere and national sphere also by integrating other methodological approaches like expert interviews into the research concept would have been able to create deeper insights or to validate the outcomes.

Keywords: Political imperative, transport policy, decision making, mobility future, transport sector.

1. Introduction

This paper is an outcome of INTEND, an H2020 project with the goal to deliver an elaborated study of the research needs and priorities in the transport sector. INTEND aims to develop a transport agenda to pave the way to an innovative and competitive European Transport sector. Three elements are considered relevant for assessing long- term strategies:

- Technological advances and forward-looking projects;
- Future transport concepts;
- Political imperatives.

This paper focuses on the Political Imperatives (hereafter PIs). PIs are relevant because policies are the direct and indirect result of political imperatives, and via direct regulation or via defining market rules, those policies address future transport concepts and technologies.
Considering INTEND goals and work-plan it is not the task to assess the identified Political Imperatives and their probability in developing real-world policy, or their importance for the future of the transport system. It is instead a central goal of this report to show a snapshot of predominant forward-looking Political Imperatives. This is done with relevance by type, spatial provenance, originator and addressee. They will moreover be clustered according to the dimension listed in the previous chapter.
In order to address this work, we identify four tasks:

1. Identification of relevant sector-specific Political Imperatives (hereafter PI) and visions in Europe;
2. Identification of relevant sector-specific PIs and visions outside of Europe;
3. Comparison of sector-specific European and non-European Imperatives and visions;
4. Identification of the most important ones to serve as an input for T 3.2.

It is important to clarify that a PI can be either the formulation of a demand/ claim or goal/ intention to reach a desired target state. But it can also be the formulation of a demand/ claim or goal/ intention to implement a certain policy or action in order to reach a previously defined target state.

2. Methodology

Considering the magnitude of the task, it is indeed necessary to develop an adequate approach and a sound methodology, those able to filter and structure the worldwide ensemble of existing PIs that are – at the moment – part of the political discourse or deemed as putatively relevant for the future development of the transport sector in , formulated by and to whom, are at the moment part of the worldwide political discourse or deemed as putatively relevant for the future development of the European transport sector?
The approach that has been developed to answer this question and therein included aspects is using Mayring's method of qualitative content analysis (Mayring, 2002). Seen before the background of a challenging timeframe and

[2] Corresponding author: massimo.moraglio@tu-berlin.de

limited capacities, this method shall guarantee that:

- Relevant sources containing important PIs are being identified and scanned (efficiency and effectiveness),
- Relevant PIs can be extracted from the sources identified,
- Interrelations between content, addressee and originator are made visible in a best possible way.

Following Mayring (2002), the main basic concept of qualitative content analysis describes the process of "…analyzing texts [material] in a systematical manner, by using a category system that is being developed, based on the material given in a theory-based way" (Mayring, 2002; p. 114; see also Ramsenthaler, 2013; p. 23 [translated by the author]).
This means that this method's main purpose is to summarize text and therein included messages (content) that are being "translated" into categories organized in a specific system. The resulting "coded" and "categorized" text passages form the basis for further content-related analyses and the interpretation of the results in relation to the formulated problem (Ramsenthaler, 2013; p. 23).
For this reason, "Content analysis is not a standardized instrument that always remains the same; it must be fitted to suit the particular object or material in question and constructed especially for the issue at hand. This is defined in advance in a procedural model, which defines the individual steps of analysis and stipulates their order." (Mayring, 2014; p. 39).
Mayring differentiates four central characteristics of the approach. These are as follows (Ramsenthaler, 2013: 25 [translated by the author]):

- Assignment to a communication model,
- Adherence to a systematic analytical procedure,
- Category-centeredness,
- Quality criteria.

These characteristics find their expression in the procedural model, depicted in Figure 1.

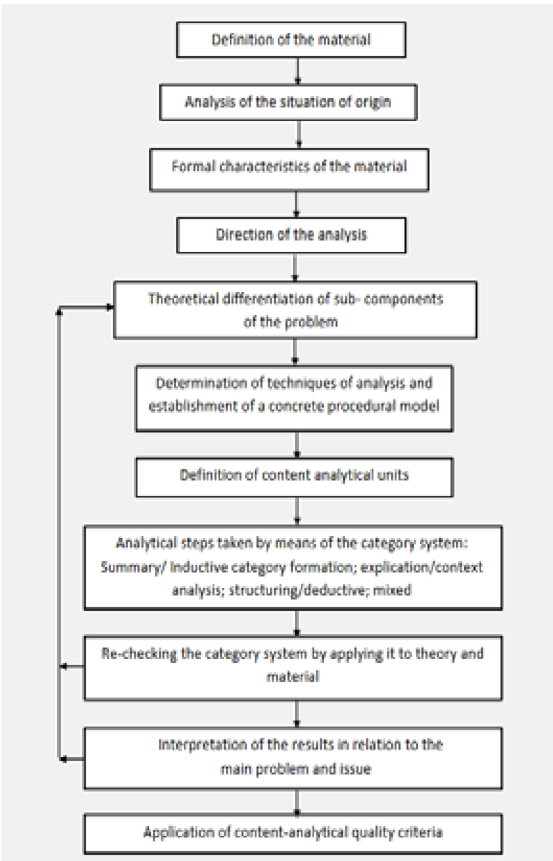

Fig. 1.
General content-analytical procedural model
Source: (Mayring, 2014; p54)

The model can again be summarized into four basic working steps:

- The first step comprehends a detailed examination of the research subject, the research question, the related material as well as of its communication model.
- The second step focuses on the determination of analytical techniques and the development of a concrete

procedural model for the analysis.

The third step consists of the actual analysis. Here the material is being reviewed based on an inductively, deductively, mixed form of both developed category systems. Thus, the content analysis can result in different kinds of outputs. These are as follows: summary, explication, structured material or mixed forms.
The fourth and last step aims at interpreting the results in relation to the main problem and issue.

2.1. Operationalization

As already mentioned in the preceding chapter, the content analysis is not a standardized instrument, hence its procedural model needs to be adapted to the specific analytical goal. In this specific case, we consider as first task to investigate define the research subject itself. This creates the main prerequisite for identifying adequate literature containing relevant PIs. Moreover, this very first step is – at the same time – delivering a part of the basic structure for building the before mentioned system of analytical categories.
Without wanting to anticipate the working definition of the term "Political Imperative" for INTEND, it is common understanding that imperatives are always target- or goal-oriented.
When a simplified communication model such as the one by Lagerberg (1975) – illustrated in Figure 2 below – is applied to the case of a PI, then it becomes clear that PIs can besides their main content distinguished by originator (source) and/ or recipient (addressee).

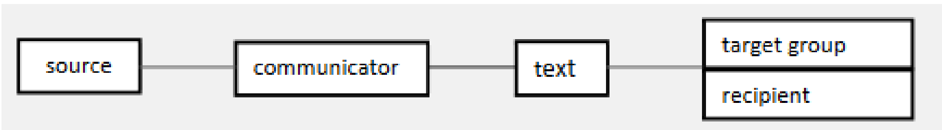

Fig. 2.
Simple content-analytical communication model (Lagerberg, 1975 cited by Mayring 2014:48)

Consequently, a reasonable approach for identifying relevant literature would be to investigate literature containing statements, declarations, demands, claims created by stakeholders having a relation to the transport sector.
An analysis of stakeholders that are influencing the discourse on transport related PIs – being originators, intensifiers and enunciators of PIs – has to be conducted. These stakeholders can be grouped in categories as follows:

- International non-governmental organizations (INGOs), Non-governmental organizations (NGOs),
- Important companies of the transport industry,
- Research institutions (in form of scientific publications),
- Supranational organizations, intergovernmental organizations,
- Governments/ ministries.

Although the European Economic Area is from an economic perspective the world's leading economic area, its future development is these days due to a further globalizing economy and emerging competitors more subject to external influences than ever before. This means that a stakeholder analysis and a search for adequate literature should also cover world regions beyond the European borders hence including also a spatial dimension.
As a result, we worked on a methodological model (see Figure 3).
After the finalization of step three – literature collection – the outcomes will be migrated to the Atlas.ti database. Atlas.ti is a scientific software for qualitative data analysis. With the help of this software, text passages containing transport related PIs can be coded (e.g. categorized according to Mayring). This is an approach that combines deductive and inductive category and it has been chosen in order to develop the category system. The deductive set of categories consists of the ones previously defined, namely geographic region of origin, kind of stakeholder being the originator, kind of stakeholder being addressed.

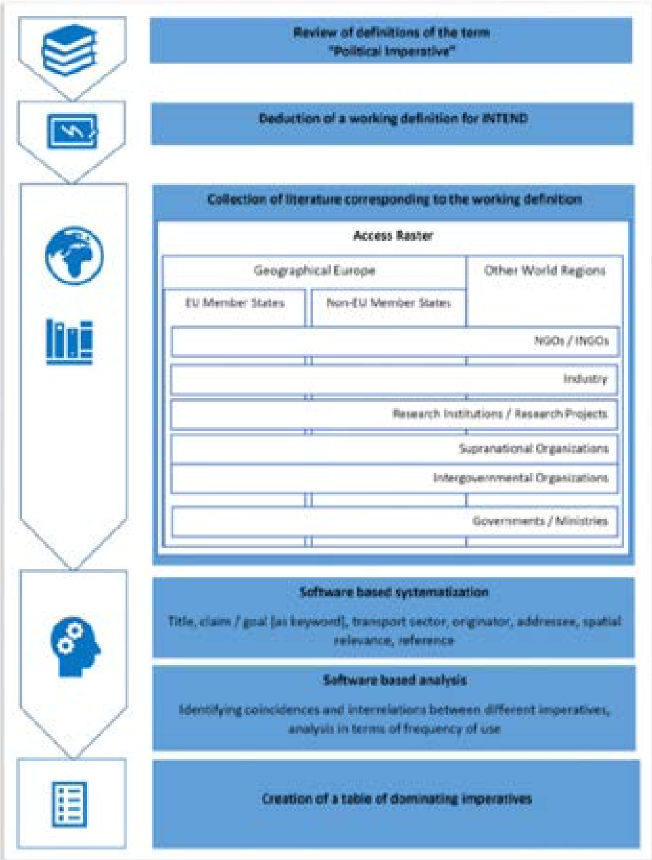

Fig. 3.
Methodological approach and research process for D 2.3

The inductive set of categories – the ones that are being developed during the literature review – consist of the content related ones, meaning the imperatives themselves (claim, formulated demand, notice of intention) and the part of the transport sector that is being addressed.
This asked for a reiteration of the research. In other words, after a first round of categorization, additional sources that may be relevant to the research subject and which have not yet been identified during the first step will also emerge. These texts are subsequently added to the collection of all sources and are also taken into account in the further procedure. Indeed, after approximately a third of the literature has been coded, the inductively developed set of categories – the content related ones – will have to be consolidated and reduced. This process is being performed by merging codes with the same meaning or generalization of existing ones in order to subsume a certain number of codes under a top-level code with a more generalized message.
The final product of this whole process is a database containing a huge amount of literature whose texts have been summarized and structured in form of codes. This allows to perform different kind of analyses in order to identify overlaps, as well as interrelations between different codes (categories). Moreover, the software also allowed to perform quantitative statistical analyses. This included analyses of appearance frequencies and overlaps with other codes (code-co-occurrence). In this way, the aforementioned category system can indicate which imperative was formulated in which region, how often by what kind of author to what kind of addressee.
These results will be summarized in form of table, and the identification of the more often appearing PIs. Since all the collected literature has been fully read, assessed and coded, the list will also contain PIs aside the mainstream, which let us to identify alternative paths that are not yet part of the political discourse. Here a comparative analysis will show which demands/ claims that have been formulated to the political sphere have found entrance to the discourse about the future transport system and are already part of the intentions formulated by the political sphere.
These working steps address the Objectives 1, 2, 3 as stated in Chapter 1. The final table will consist of the main columns, visible in Table 1.

Table 1
Column headers of the results table

Political Imperative Demand/ Claim, Intention (as keyword)	Origin	Frequency of Occurrence	Sector being addressed (Frequency)

Besides the development of the table comprising PIs as an input for Task 3.2, a sector-specific comparison regarding the European and Non-European imperatives and visions for the transports sector will be performed. This working step addresses the Objective 3, as stated in Chapter 1.

3. Defining the Term "Political Imperative"

It is not in the scope of INTEND to offer an in-depth and theoretical analysis of the term "Political imperative" (hereafter PI), nor to define its philosophical backgrounds in Western culture (which is mainly built after Kant´s deontological moral philosophy). Still it is useful to briefly assess the concept, so to better frame the activity of project and better address the H2020 call´s goals.

3.1. Semantic Change – A Review of Definition and Actual Use

In this regard a definition of what a PI has to be offered. Following Trebilcock, the variety of meanings about "normative" is "startling" (Trebilcock 2014, p. 9). Political imperative has been dubbed as political visions, or "political culture", "political agendas" or "political ends" (Savage and Kong 1993). In order to offer a common stand point, after Trebilcock´s suggestion, we assume that (political) imperatives are "perspectives or theories that purport to advise governments on what policies they should adopt in this context as a matter of efficiency, fairness, justice, or some other conception of right and wrong" (Trebilcock 2014, p. 9).

In this respect, Political Imperative looks like a very strong tool, which should address strategic view and public decision in every field of action of political actors. These PIs can be manifest or not. Some PIs don´t need any formulation, being part of a general political concept, universally accepted, which does not need to be explicit (for instance the idea of the state protecting its citizens, or the state´s monopoly in managing justice). This means we have no written PIs because around some arguments there is an unquestioned idem sentire de republica.

On the contrary, if PIs are manifest, this means that the value portrayed by the PI is not (yet) perceived as fully part of the political discourse. In these cases, the PI is the result of declining value previously given for granted, shifting perceptions, or new threat to social live. A pertinent example is the climate change, which asked a change in the existing policies and, thus, to reach new goals (as for Co2 emission reduction, energy saving etc.).

So, one manifest, the PI can have a variety of backgrounds and goals.

1. PIs are developed in order to enforce an idem sentire which is largely accepted, but still not fully in the political, social or economic debate and practise (e.g. Co2 reduction);
2. Explicit PIs are necessary in defining a sense of urgency and the need of action, which goes beyond the mere agreement on the issue (e.g. EU policy on climate change);
3. PIs can be a top-down action so to build an idem sentire on issue which are not yet portrait as crucial by a larger pool of stakeholders (e.g. industry competitiveness).

This let us to define the PI as a tool to shape the political debate and to inform consequently policies able to reach the designated goal.

It should thus be clear that PI´s goal - by its own nature – is addressing at large fundamental concepts, and "to advise governments on what policies they should adopt". In other words, a PI is an indication of a desired target. It is true that PI presents itself with very strong definitions, encompasses both the word "political" (e.g. the state monopoly of power) and the word "imperative" (e.g. something absolutely necessary or required; unavoidable), but the combination of the two into PI does not represent in se a policy. PIs are instrumental in nudging stakeholders and citizens to inform their actions towards desired goals. In this vein, a PI in se does not define (practical) action for the achieving of the portrayed goals, nor builds a roadmap.

In this regard, the concept of PI resembles normative scenarios, being the latter also used as a suggestion in formulating public policy able to reach a designed goal. This leads us to understand also why PIs and normative scenarios can overlap and how both can have strong value and clear target (e.g., 50% Co2 emission reduction for 2050), but they still have very vague strategy for the achievement of their targets.

Finally, PIs can vary according to time, geographies and "producers".

About time, if we focus on the transport field, it is interesting to remark how a (explicit) PI of the past was the motorisation of agricultural work and transport, with little or null awareness of the long-term consequences (Ladd 2008). The consciousness of externalities has changed this PI, and new PIs are now aiming to not-motorized transport solutions, especially in urban areas.

About geographies, PIs can vary, even dramatically, according to local characteristics and situations. Thus, PIs can be having divergent or even clashing goals. For instance, the role of climate change in formulating PIs is indeed crucial in many governmental circles, both in Europe and Asia, but is marginal (or even denied) in USA (at least at the federal level).

Indeed, the case of USA introduces to the question of the PI "producers". In that case, while the federal government is refusing to inform its policy and its PIs according to climate change and transition toward sustainability, several USA states still address their own PIs in line with those objectives. This leads us to define PIs as the result of national, international and supranational governmental bodies´ action. Just to add more complexity to the picture, also intergovernmental organizations are PIs producers. In this symphony of PIs, we can also aspect private actor's and stakeholder´s attempt to lobby their interests, and thus shape the debate and the PIs formulation.

3.2. Political Imperatives in Transport Research and Planning

Once we move to a more detailed understanding of PIs engaging the transport sector, still we realize the need of a preliminary and notional framing of the concept. We have seen as PIs are assuming the form of commendation in formulating public policy. But, often, and exactly because of their goals (large and general in the scope), not always PIs are precise in their devising. Some PIs are very clear and self-evident: EU´s PI of keeping European industry competitive in a global scale is a great example. Another good example is EU Co2 reduction goal: while many if not all of us can agree on this PI, it is also true that we need more information about the PIs, so to understand if they need to be part of our investigation about the transport sector. This is a slippery issue, because often PIs address issues which impact transport policy, though they don´t openly address topics or issues immediately linked to transport. PIs on Co2 emission reduction for instance deal with a more general environmental argument, but without doubt transport is of the main filed of implementation. Sometime the connection is less straightforward. Social inclusion is an important PI, with a growing relevance and here it comes the twist: the role of transport in shaping social exclusion (or vice versa to shape inclusion) is gaining traction…

This situation asks us to define two methodological line of action:

- In first place we need to identify those PIs which are really tied up with the transport sector, regardless of the definition of the topic;
- In second place, once the selection of those PIs is accomplished, we should consider and analyse only those PIs which are part of INTEND range of action and interpretation (e.g. "Identify the main transport research needs and priorities").

3.3. A practical Definition of PI

At this stage we can finally shape a practical definition of PI, one that fits the scope of the project and, more in detail, this deliverable.

We assume that, as Fig. 4 illustrates, PIs are of a dichotomous nature:

1. They are "…perspectives or theories that purport to advise governments on what policies they should adopt in this context as a matter of efficiency, fairness, justice, or some other conception of right and wrong" (Trebilcock 2014, p. 9).
2. In the context of specific perspectives and theories, Political Imperatives are notices of intention to implement specific policies/ to reach specific goals, in order to achieve efficiency, fairness, justice, or some other conception of right and wrong purported to be adequate.

This deliverable aims to identify PIs according to their actual field of engagement, regardless of their labelling or definition.

It, moreover, focuses on those major PIs affecting "economic efficiency, competitiveness, sustainability, user convenience and inclusiveness" (European Commission, 2015).

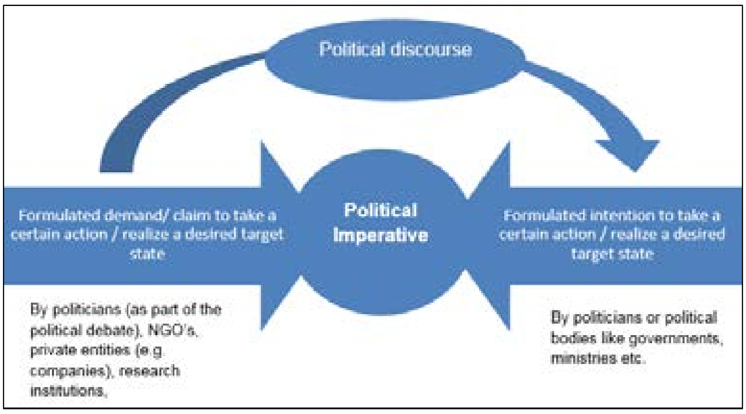

Fig. 4.
A practical definition of the term "Political Imperative" for INTEND

4. Stakeholder Analysis and Compilation of Political Imperatives in the Transport Sector

4.1. Stakeholder Analysis/ Collection of Literature

As described in Chapter 2, qualitative content analyses always bear the risk that the selection of adequate sources as well as the assessment of their contents are being influenced by subjective actions of the scientist/ person working on the analysis itself.

In order to minimize this risk Chapter 2.1 already underlined that clear criteria for literature selection and assessment have to be fixed right in the beginning. The involvement of more than one person, double-checking of the appliance of latter mentioned criteria as well as an intensive critical reflection of first results and a continuously critical reflection during the collection and assessment phase can also safeguard to keep the influence of bias as a result of subjectivity as minimal as possible.
During the phase of stakeholder analysis and literature collection, criteria have been applied as presented in Table 2 and Table 3
The global criteria were the guiding principles valid for the whole stakeholder analysis and collection of literature. The criteria presented in Table 3 have been applied stakeholder-type specific.

Table 2
Global criteria

Criterion	Description/ Explanation
Internet search engines	Google, Qwant, Yahoo, Bing
Search queries	For the literature research, the search terms were mostly entered directly into the search function on the websites of the specific stakeholders previously identified as relevant. The following search terms were used: 'future', 'transport', 'mobility', 'future of transport/mobility', 'transport strategy', 'transport policy', and 'infrastructure development plans'. Often it was also possible to get results through using the menu function on a certain webpage. When searching on research platforms, the terms were entered directly into the search engine of the specific scientific research platform.
Use of direct sources	• Only literature/ sources of information of the stakeholder itself or produced based on a subcontract have to be used. This shall safeguard capturing the intention/ demand that has been formulated by the stakeholder and not capturing the interpretation of another party that might be subject to influences of a third party. Example: Transport Strategy of a government instead of EC country reports. • Statements in press and media are not to be included for following reasons: 1. Statements in local/ regional/ national press and media are often depending on politics of the day and are thus seldom valid for a longer period of time. 2. Statements in press and media are often formulated in the respective national language. Thus they are seldom reaching the international discourse (only indirectly as an interpretation by international press agencies). Scanning national press and media as well as would have resulted in unpredictable additional efforts (language) and many uncertainties (gaining a balanced picture).
Actuality	• Only sources pointing to the near and far future have to be considered. This also includes statements regarding the assessment of the current • For transport strategies of governments/ ministries the year of this study (2018) had to fall into the period of validity of the concept/ strategy.
Language	• Only sources in English language have to be considered, for two reasons: • Publishing reports and statements in English language –especially via governmental/ ministerial channels – is an indicator that the publishing entity is actively participating in the international discourse. • Assessing reports and statements in other national languages would have been resulted in unpredictable efforts or resulted in an unbalanced picture of the discourse.

Table 3
Stakeholder-specific criteria

Stakeholder	Criterion
Websites and reports of International non-governmental organizations (INGOs)	• The reports and statements of interest should focus on a global scale or at least on one specific region covering more than one country.
Non-governmental organizations (NGOs)	• The reports and statements of interest should focus on a certain region or more than one country. • Reports and statements of national NGOs should not be included to avoid creating an unbalanced picture.

Important companies of the transport industry	• Companies of the transport industry have their headquarters in one country. In order to avoid creating an unbalanced picture only globally operating companies will be included. The sectors investigated are as follows: Consultants, Oil/ Gas Companies, Logistics Companies, Automobile Producers, Conglomerates, Maritime/ Shipping Companies • For the identification of the most important, globally operating enterprises in the field of transport, the ranking list of the business magazine Forbes was used, which can be found at the following address: https://www.forbes.com/global2000/list/. The first five
Supranational organizations, intergovernmental organizations	• Reports of supranational and intergovernmental organizations will be differentiated according to their spatial relevance: Global, Europe, Other world regions
Governments/ ministries	• State structures and ministerial organization/ responsibilities vary from country to country. • In order to include imperatives formulated by the political sphere of the most important economies official governmental websites of countries with the ten largest GDPs have been scanned. The underlying assumption was that these big economies with their huge transportation markets have an important influence on the direction of the discourse regarding the future transport system [science, research and development, production, consumption, implementation]. • Since Europe is the main focus of the Intend project, reports and statements by the political sphere in Europe are of special interest. • For the EU 28 governmental websites and websites of the respective ministries have to be scanned in order to extract relevant statements and reports. • Since countries of Geographical Europe have strong economic/ societal/ political/ scientific relations with EU member states or might be future member states reports or statements by their political sphere regarding the future of the transport system is of special interest as well. Therefore their governmental websites, independent from the country's size or economic power, have to be included in the scanning process.
Science	Research and science play a key role in developing concepts and scenarios for a future transport sector. Although the influence of third-party funded research is constantly rising – putting the research's independence at risk – publications in international journals have usually undergone profound review processes assuring that the results presented have been derived based on adequate research design. Therefore only peer-reviewed scientific articles will be included. The scientific search engines that will be used are: sciencedirect.com, scholar.google.com, and webofknowledge.com

In order to avoid bias resulting from subjective perceptions of the transport sector the internet has been scanned for potential sources by more than two researchers, possibly with different backgrounds. For each type of stakeholder group the results have been discussed afterwards before the respective stakeholder found its way onto the stakeholder map, presented in Annex 1 and before the related report/ statement became part of the literature list.

4.1.1. Results

As a result of the stakeholder analysis and literature collection altogether 135 sources for political imperatives have been collected. This material comprises around 7,920 pages of information. As stated before, the material identified can be based on the communication model assigned to certain groups of stakeholders.

With regard to these numbers it has to be sated that governmental reports are nearly forming a third of the material that has been identified as relevant. The reason for this is that this deliverable also tries to capture imperatives by the political sphere.

In order to guarantee a comprehensive snapshot of the "state of imperatives" in Europe as well as outside of Europe, governmental and ministerial homepages of all EU member states have been scanned for relevant sources. This also with the purpose of later associating the European "state of imperatives" with the context of the worldwide "state of imperatives".

Here, it has to be mentioned that for the different groups more material has been searched and initially assessed, but that only material of those stakeholders was finally included that fulfilled the global and stakeholder-specific criteria, that have initially been set. For stakeholders marked in "orange" no material in English language could be identified. Although French and German are also official European languages the international discourse is taking place in English. Therefore, it can be assumed that information that is not being provided in English especially by governments and ministries faces higher barriers to find entrance to the international – partly also European – discourse.

Moreover, some material has been produced/ published by the same stakeholder. This is for example the case concerning big organizations like the European Union or the World Bank.

The whole list of the collected material with clear references can be accessed via the publicly available INTEND deliverable D 2.3 under www.Intend-project.eu/publications.

4.2. Adding Literature to the Atlas.ti Database

The computer programme Atlas.ti offers the possibility to add different document types to the before created project and to use them for evaluation: not only text documents, but also web pages, geo data, audio and video files.
For this analysis text documents only e.g. PDF-files, HTML-files and doc-files were used, which were identified as suitable sources during the literature research. As described in Chapter 4.1., websites and reports of International Non-governmental organizations (INGOs), Non-governmental organizations (NGOs), important companies of the transport sector, supranational organizations and intergovernmental organizations, governments/ministries and scientific research were used. To prevent any interpretation by a third party, only sources directly from the respective stakeholder were used for the study.

4.2.1. Results

With regard to the imperatives themselves it can be stated that for each field – demand/ claim or intention – every time a relevant passage had been identified a new code was created or the passage was assigned to an already existing code. As a result, the huge number of imperatives had at the end of the assessment process a frequency of occurrence of "1", "2", or "3". Although most of the resulting imperatives could – during the phase of generalization/ merging – be assigned to a top-level code a huge number of imperatives only occurring once or twice could not been generalized respectively summarized with another code. Altogether the original amount of around 633 identified demands/ claims and around 847 identified intentions could be generalized to 137 demands/ claims and 149 intentions respectively. This results in higher frequencies of occurrence per imperative allowing to identify those that seem to be of more or less importance.
For the demands/ claims it can be stated that around two thirds of identified demands were less than four times found in the different sources that have been assessed and could not be further summarized respectively merged with higher frequency codes.
As a result, although demands/ claims with a frequency between 42 – 5 are only representing one third of the frequencies identified, they are representing 70% – around two thirds – of the marked passages in all sources.
For the intentions it can be stated that more than two thirds of identified demands/claims were less than four times found in the different sources that have been assessed and could not be further summarized respectively merged with higher frequency codes.
Although intentions with a frequency between 42 – 5 are only representing one third of the frequencies identified, they are representing 76% of the marked passages in all sources.
Again, it must be stated that also the process of generalization and merging is based on the interpretation of the content hence potentially subject to misinterpretation.
Moreover, naturally, imperatives vary with regard to their level of detail, why they are sometimes difficult to distinguish from each other what can sometimes result in overlapping.
For the demands/ claims the imperatives having the highest frequencies (7 – 45) of occurrence are shown in Table 4. Table 5 does moreover illustrate in what kind of source the respective demand/ claim has how often been spotted and what it is directed to.
Correspondingly, Table 6 and 7 illustrate the spotted formulated intentions, their origin and targets.
Demands/ claims and intentions with lower frequencies than 7 can be reviewed in the full INTEND Deliverable D 2.3. accessible via the website www.intend-project.eu/publications.

Table 4
Formulated demand/ claim to the Political Sphere - based on Atlas.ti Code (see results in Table 5)

No	Formulated demand/ claim to the Political Sphere - based on Atlas.ti Code (see results in Table 4)
1	Reducing climate related externalities (esp. GHG, noise emissions, land take of corridors/ hubs) by implementing different measures (climate action plans, sup. green private investments, enforcing cap trade etc.)
2	Supporting industries and science in developing and implementing innovative fuel technologies (battery technology, advanced bio-fuels), raising awareness for alternative fuels
3	Revision, enforcement of safety standards, industry-independent certifying organizations, integration of safety aspects in planning frameworks (SUMP), harmonization of regulations (speed limits, vehicle safety, zero alcohol tolerance, helmet wearing), European safety agency
4	Vehicle efficiency as a key factor to gain more energy efficiency/ reduce consumption
5	Closer public and private cooperation (private investments in the network need to become more attractive [incl. PPP])
6	Supporting modal shift (aviation to rail or inland waterway, motorized to public transport/active modes)
7	Modernizing/ extending (peak hours) Urban Mass Public Transport Systems (impr. energy efficiency, and marketing)
8	Raising investment in infrastructure development (modernization, capacity upgrade) in rural and urban areas

9	Standardization, harmonization,adaptation of regulations on EU level (cross-border road conventions, single European Sky Initiative)
10	Revision of fuel and power taxation as well as regulation standards (reducing subsidies, clear indexing [also of impacts] for comparability)
11	Reliable, economical, affordable and environmentally friendly energy supply
12	Combination of electricity, transport and heat sector based on renewable electricity, bio fuels (sector coupling)
13	Controlling or reducing travel demand
14	Further developments in technology necessary (also vehicle technology: EV's, modular vehicles, innovative materials)
15	Higher efficiency of transport systems
16	Incentives/ awareness raising campaigns for fleet electrification (buses, private vehicles, rail); public and commercial procurement
17	Increasing connectivity, intermodal access and fit-for-purpose network standards
18	Investments in research and development activities must be strengthened
19	Coherent EU framework for autonomous vehicles (infrastructure investments, safe deployment, regulations for the transitional phase, reform of vehicle safety approval regime, regulation, registration)
20	Digitization strategy/ regulations/ markets at national, European and international level (incl. transport sector)
21	Improving bulk transportation methods for long distance freight transport (rail/river)
22	Innovative research system (stronger evaluation and coordination of research policies and their impact, international research in strategic fields, long-term [basic] research, supporting side-paths
23	Political measures must be transparent and predictable
24	Exploitation, piloting of new technologies must be promoted/ regional test beds for experiments, failing should be part of the ecosystem
25	Harmonized development activities and systematically implement a comprehensive vision for a competitive and sustainable European transport system and industry
26	Higher rate of vehicle occupancy
27	Improved risk management (legislation, data and information sharing, risk quantification metrics, scenario planning, two way information sharing)
28	Increasing hub capacities (ports, airports, stations)
29	Market opening needs to go hand in hand with quality jobs and working conditions
30	Research and planning should follow a holistic perspective on transport and mobility (consumer preferences, perceptions, behavioral aspects)
31	Research related to autonomous vehicles (environmental impact, impact on mobility behavior, human-machine interfaces in vessels, cyber- and data security, infrastructure investments, planning policies)
32	Universal application and enforcement of high working standards (safety/security, environmental protection, working conditions, payment)

Table 5

Short-listed Demands/ Claims (Imperatives) to the political sphere

Table 6

Formulated intention by the Political Sphere - based on Atlas.ti Codes (see results in Table 7)

No	Formulated intention by the Political Sphere - based on Atlas.ti Codes (see results in Table 7)
1	Sustainable transition of energy supply and transport sector (low emissions, electrification, bio-fuels)
2	Improving safety standards (vehicles and infrastructures, incl. innovative technologies [C-IST]); safety training (emphasis on vulnerable groups)
3	Developing public transport systems (demand-responsive, comfortable, accessible, barrier-free, affordable, attractive, efficient, subsidized, innovative [mobility chains])
4	Improving connectivity within and of regions in a national and international (incl. European) context (incl. cross-border commuting)
5	Investments in transport infrastructure (arteries [incl. oil and gas distribution infrastructure] and gateways [airports, ports, train stations])
6	Improving intermodality
7	Increasing competitiveness and efficiency through organizational, management and functional optimization (incl. new
8	Implementation of intelligent transport systems (incl. autonomously driving vehicles)
9	Increasing efficiency and capacities (incl. elimination of bottlenecks)
10	Creating incentives for a modal shift, favoring environmentally-friendly modes
11	Fleet renewal and electrification
12	Supporting high speed connections, reducing travel times between cities
13	Strengthening national/ international competitiveness
14	Improving cost-effectiveness and sustainability of the financing system, developing innovative financing models
15	Reducing travel demand (e.g. by demand reducing land use structures, better communication infrastructures)
16	Improving security/ security training
17	Improving the quality of the railway infrastructure (TEN-T, freight corridors)
18	Minimization of negative impacts (externalities regarding health and climate) of transport and infrastructure
19	Improving accessibility (also for persons with reduced mobility)
20	Creating attractive infrastructures for slow modes
21	Research and development of new fuels and new transport technologies
22	Supporting ICT, open data
23	Development towards MaaS
24	Strategy development together with policy makers, science and industry
25	Improved connectivity to support growth of tourism industry
26	Increase competition in national rail market
27	Developing/ harmonizing rules concerning data collection (ownership, management etc. vehicle registration, road traffic crashes, drivers licenses, status of infrastructures), improving data quality, using innovative technologies for data collection
28	Transport sector should be privatized (passenger and freight)
29	Developing a climate change adaptation approach
30	Increasing capacities and qualities of airports
31	Creation of recharging and refueling infrastructure networks
32	Establishing a single African air transport market
33	Improving airport accessibility and predictability of first and last mile connections (passenger and freight)
34	Supporting local SMEs
35	Transport should promote environmental and urban sustainability

33	0	0	1	0	0	1	0	5	0	0	0	0	7	3	1	1	0	2	1	0	0	1	0	0
34	0	0	0	0	0	0	0	7	0	0	0	0	7	1	1	0	1	0	1	0	0	0	3	1
35	0	0	2	2	0	2	0	1	0	0	0	0	7	0	0	0	0	1	1	3	0	0	2	0

As a general outcome, it is remarkable that the imperatives with the highest frequencies are the ones that have the goals of making the transport sector more sustainable and safe and are thus targeting the whole sector. This includes PIs with goals of reducing GHG emissions by supporting modal shift, substituting the source of energy (EV's, alternative fuels) or using existing infrastructure more efficiently are making up the majority. For the demands/ claims 15 out of 32 imperatives are addressing this topic. For the intentions 13 out of 35 imperatives are addressing this topic.
On both lists the aspect of traffic safety received a quite high ranking (Demands/ Claims Rank 3, Intentions Rank 2) and the imperatives are over proportionally often targeting road transport.

4.3. Demands/ Claims

In general, it can be stated that the demands/ claims focus mainly on the creation and implementation of clear and reliable frameworks and regulations. This is the case for the demands/ claims 1, 2, 9, 10, 19, 20, 23, 25, 27 and 32 as shown in Table 5. Here an important point is especially the harmonization of standards, rules and regulations inside the European Union (e.g. soft-policy tools). Forward looking imperatives are especially touching urban transport and data issues. Here the imperatives are demanding:

- A standardized EU-wide framework for autonomous driving vehicles, including the transition phase;
- A digitization strategy for the transport sector (including clear and secure standards for data generation, management and privacy);
- Harmonized development activities and a systematically implementation of a comprehensive vision for a competitive and sustainable European transport system and industry (preserving the competitiveness of the fossil fuel industry).

According to the imperatives identified, the development and implementation of new technologies should be fostered by stronger financial commitment of the governments – also by regulatory measures like fair fuel taxes – but also by raising the attractiveness for private investors. Moreover, there are demands/ claims that are not exclusively targeting further growth, extensions of infrastructures. The imperatives 4, 12, 13, 15 and 26 are stressing the point of reducing the use of existing capacities, raise efficiency levels – e.g. by creating synergies via sector coupling – or increase levels of vehicle occupation.
Some demands are also stating that the costumer should be able to make informed decisions, as for example in the cases of mode choice, vehicle procurement, and fuel-consumption. According to the related imperatives this can be reached by implementing information campaigns, an implementation of transparent and comparable pricing standards, but also via an advance information tool (carbon footprints of possible mobility alternatives), as stated in the imperatives 2, 7, 10 and 30.

4.4. Intentions

The intentions are also mostly focused on the transport sector in general. The two most important targets are i) to realize the transition of the energy supply (electrification of the transport sector) and ii) to improve traffic safety. The latter imperative is mostly related to road transport. Altogether, 11 out of 35 imperatives formulated policy intentions to directly or indirectly reduce the negative impacts on the environment. In general, it can be stated that imperatives pointing to standardization, harmonization of regulations were in the short-list of the intentions – with one exception – completely missing.
Instead, the imperatives were more often pointing to a local, regional, national, international integration of physical networks to improve connectivity or accessibility and thus create a more attractive climate for enterprises. Here 8 out of 35 imperatives were directly or indirectly addressing this target. These were the intentions 4, 5, 12, 17, 19, 25, 32, 33. Another often mentioned topic was the one that targeted an optimization of existing networks (nodes and hubs) by reducing bottlenecks or extending existing capacities. This topic has been addressed by the imperatives 3, 5, 7, 9, 12, 30. A general observation that can already be made even by having a quick look of Table 6: the imperatives are in equal measure addressing most of the target sectors. While the demand/ claims were mostly focusing urban transport systems, it can be observed here that also rural transport seems to play an important role. Additionally, aspects like barrier-freedom or accessibility of vehicles and areas are more often mentioned. This is of course related to the kind of source and stakeholder.
So, the forward-looking intentions (imperatives) that have been mentioned are:

- Increasing competitiveness and efficiency through organizational, management and functional optimization (incl. new technological solutions);
- Implementation of intelligent transport systems (incl. autonomously driving vehicles);
- Improving cost-effectiveness and sustainability of the financing system, developing innovative financing models;
- Supporting ICT, open data;
- Development towards MaaS.

4.5. Demands/ Claims and Intentions with Relation to Research

Generally speaking, the sources used addressed more often demand and claim than intentions. Highest frequencies can be reported for the technology-based research, such as:

- Supporting industries and R&D in developing and implementing innovative fuel technologies (incl. battery technology, advanced bio-fuels), related infrastructure development as well as raising awareness for alternative [incl. electric] fuels;
- Research on traffic safety;
- Further developments in technology necessary (also vehicle technology: EV's, modular vehicles, innovative materials).

Other demands/ claims were formulating respectively suggesting a reform of the research environment itself or research on the impact of new technological solutions, transport systems:

- Investments in research and development activities must be strengthened;
- Innovative research system (stronger evaluation and coordination of research policies and their impact, international research in strategic fields, long-term [basic] research considering the innovation cycle, supporting side-paths in risky but promising research fields [where failing is too expensive for private research);
- Exploitation, piloting of new technologies must be promoted/ regional test beds for experiments, failing should be part of the ecosystem;
- Research and planning should be realized/ conducted following a holistic perspective of transport and mobility (consumer preferences, perceptions, mode choice, behavioral aspects);
- Research related to autonomous vehicles (environmental impact, impact on mobility behavior, human- machine interfaces in vessels, cyber- and data security, infrastructure investments, planning policies).

For the intentions only five imperatives related to research and development could be identified. These were more related to the development of strategic approaches or innovative policies:

- Improving cost-effectiveness and sustainability of the financing system, developing innovative financing models;
- Research and development of new fuels and new transport technologies;
- Strategy development together with policy makers, science and industry;
- Developing/ harmonizing rules concerning data collection;
- Developing a climate change adaptation approach.

5. Summary and Outlook

This meta-analysis has assessed altogether 135 different sources by stakeholders with relation to the European and global transport sector. A software supported qualitative content analysis of around 8,000 pages led to the result that altogether 286 political imperatives – 137 demands/ claims formulated to the political sphere and 149 intentions formulated by the political sphere– have been identified.

Imperatives that are amongst other aspects directly or indirectly having the goals of reducing GHG emissions by supporting modal shift, substituting the source of energy (EV's, alternative fuels) or using existing infrastructure more efficiently are making up the majority. For the demands/ claims 15 out of 32 shortlisted imperatives are addressing this topic. For the intentions 13 out of 35 shortlisted imperatives are addressing this topic.

Moreover, on both lists the aspect of traffic safety received a quite high ranking (Demands/ Claims Rank 3, Intentions Rank 2) and the imperatives are over proportionally often targeting road transport.

In general, it can be stated that the demands/ claims are rather focusing the creation/ implementation of clear and reliable frameworks and regulations. On the contrary imperatives pointing to standardization and harmonization of regulations were – with one exception – completely missing in the short-list of the intentions. Here, an important point is especially the harmonization of standards, rules and regulations inside the European Union.

Forward looking imperatives are especially touching urban transport and data issues. Here it can be stated that the imperatives coming from the European stakeholders were much more forward looking and that topics like intelligent transport systems, MaaS, green logistics have already – although quite weak – already found entrance into some strategy papers.

Nevertheless, there were still demands that might become more relevant in future and have yet not been sufficiently considered. These demands mostly relate to the development of long-term strategies in order to create also a reliable development for the economy. This touches topics like a digitization strategy for the transport sector, a strategy to apply and enforce high working standards also to safeguard a sufficient amount of workforce in the transport sector.

Other demands strongly point to research and development in sharing services, autonomous vehicles which are currently revolutionizing the transport sector. This requires innovative planning strategies and ways to regulate and develop new markets into the "right" direction, which opens-up another topic. Other demands/ claims were formulating respectively suggesting a reform of the research environment itself also by taking over a new rather holistic perspective on mobility and to orient research on societal needs. An interesting imperative that has been identified as a demand and intentions was to develop ways to reduce traffic demand and to escape from the growth-spiral.

Finally, the method chosen proofed to be adequate for delivering an initial snapshot of the current state of imperatives with relation to the transport sector. However, it has to be expressed that a deeper and especially longer lasting assessment of the international sphere and national sphere also by integrating other methodological approaches like expert interviews into the research concept would have been able to create deeper insights or to validate the outcomes. This was due to the limited amount of time not possible. This deliverable has, nevertheless, created a sufficient and most of all structured overview of the most important political imperatives can be valuable source for further analyses.

SMART TRANSPORTATION PLATFORM FOR BIG DATA ANALYTICS AND INTERCONNECTIVITY

Nandor Verba[1], Kuo-Ming Chao[2], Soizic Linford[3], Eleni Anoyrkati[4]
[1,2] Faculty of Engineering, Environment and Computing, Coventry University, United Kingdom
[3,4] Coventry University Enterprises Ltd, Coventry University, United Kingdom

Abstract: Innovations in Big Data Analytics and advances in Internet of Things have changed how we collect, interpret and analyses data from Smart City and Transportation environments. Advances in Fog Computing that suggests the extension of the Cloud to the Edge of the network using resources available to reduce latencies and improve reliability fit perfectly with concepts from autonomous and connected vehicles which have increasingly powerful processing capabilities. The use of such systems for congestion management, route planning, infrastructure management and other advances orchestration techniques requires the use of varying platform and technologies together. The existing proposals and platform are mostly designed to perform a fixed set of tasks, either purpose built or not generic enough to satisfy requirements from multiple use-cases. This paper analyses existing Fog Computing and Processing platforms characteristic data types and their brokers as well as existing Big Data cluster-computing frameworks like Apache Spark and Hadoop based on capabilities, data types and preferred use-cases. Supported by this analysis we propose a conceptual polyglot Fog Computing platform for Smart Transportation scenarios that can satisfy the needs of future smart city environments and can connect to multiple platforms and perform real-time, off line and hybrid processing of data as well. We provide a high-level framework for the integration of such platforms into collaborative clustering scenarios.

Keywords: smart transportation, fog computing, big data analytics.

1. Introduction

With rapid advances in autonomous vehicles and highly connected systems in the context of smart cities and transportation as well as the ubiquitous application of machine learning and data analytics in both local and cloud environments the field of future transportation and cities is rapidly expanding branching out into several research fields.
When considering Smart Transportation and smart, their interconnection in smart grid, opportunistic networks or clusters has become an increasingly appealing challenge. Especially with the introduction of concepts from Fog Computing with the local processing and decision making as an attempt to solve the scalability latency and some of the security issues inherent with cloud and centralized computing. This comes as there is an increased need for resource intensive processing and an increased concern over data-security and storage.
The recent Fog Computing framework proposals and IoT Middleware Reference architectures there is an increasingly clear consensus on the requirements of these gateways and of the use-cases in which they would be deployed. This makes possible the development of a system that can be can answer the required modularity, interconnectivity and lower level functionality abstraction to a degree where the development of management, control and analytics components for smart cities and vehicles becomes as trivial as mobile application development.
This paper proposes an IoT and Fog based Vehicle Centric Smart Transportation platform that look at the development of Smart Localities based on Wireless Sensor Networks (WSN) using Dynamic clusters based on fixed point gateways and mobile entities such as vehicles or other gateway enabled entities that cross these static regions and interact with them. Through this paper we will present a review of some of the existing middleware or gateway platforms, their advantages and drawbacks. Furthermore, we propose a dynamic application deployment and updating mechanism for these gateway for functionality extension as well as well as an experimental setup for the testing of the deployed systems.

2. State of the Art

When considering the background work that has been done for the development of these platforms there are several things that need to be considered. Concepts and Requirements need to be considered from the IoT domain that allow these gateways to be interconnected and for the connected devices or things to talk to each other in a protocol agnostic manner. Recent approaches require that the processing and other resources of the system be virtualizable and manageable to a level traditionally associated with Cloud computing. The paradigms and virtualization layers of new Fog computing approaches come into play in such systems, where some off the computational tasks can be offloaded to the edge, reducing costs and the strain on the network. These requirements and paradigms have led to several platforms being proposed that aim to solve portions of the problem. They range from Virtual Machine (VM), Container and shared environment solution, which offer varying levels of security and performance advantages.

2.1. Internet of Things

Internet of Things (IoT) is defined as the sensing analytics and visualization done anytime, anywhere and on anything (Gubbi et al., 2013) It can be considered the interconnected network of billions of devices as Gartner estimates at least

[1] Corresponding author: verban@uni.coventry.ac.uk

26 billion devices connected by 2020 (Rivera et al., 2013). When considering the application of its concepts for Smart Cities its main advantage is the seamless integration of a large set of heterogenous devices and systems (Zanella et al., 2014).

There are several views when it comes to the tasks of IoT devices. Some see the role of edge devices and systems simply that of data whereas other proposals as in (Gaur et al., 2015) show the possibility of giving more agency to these edge devices by allowing decision making and connectivity tasks to be performed in a decentralized manor. The work in (Papadimitratos et al., 2009) looks at more complex vehicular networks where the vehicles are the network creating a large peer to peer network while (Verba et al., 2017) looks at their structure.

When considering the interconnectivity proposed by the Internet of Things, the field of Cyber-Physical Systems looks at how these systems should gather data, make decisions and interact with their environment. An overview of this can be seen in (Rawat et al., 2015) where they provide an overview of the impact of CPS on Smart vehicle systems and the impact of delays and latencies on these. The requirements of such systems can be seen in (Madakam et al., 2015) where a review of agent based systems is performed and a need for interoperability, flexibility and extensibility of such gateways which are in line with the IoT Requirements.

The processing, routing and mining of data for Traffic Monitoring, Management and Vehicle control is a crucial part of Smart Transportation systems as shown in (Chen et al., 2016), where the challenges of gathering and processing this data is mostly related to the quantity of messages and the semantics related to these sometimes, simple sensor messages.

When considering all the research, it can be said that future IoT systems will require decentralized control and analytics within highly interconnected vehicles or devices that can interact with their surroundings through some sort of local or peer networks.

2.2. Middleware and Gateway Platform Review

When considering gateways for smart city and transportation scenarios they need to satisfy the above-mentioned requirements and follow the existing directions if they are to be used as future platforms. An overview of some of the technologies and containers being used can be seen in (da Cruz et al., 2018) The overview of a few platforms implementing Fog Computing paradigms in the context of connected devices has be shown in Table 1. where they are analysed for their compliance based on the system requirements shown above.

Table 1
Overview of Fog Computing Platforms

Platform	Inter-operability	Abstraction	Container	Cooperative Behaviour	Load Distribution
(Hao, J., et. al., 2015)	✓				
(Rathore, M.M., et. al., 2016)	✓	✓			
(Chen, F., et. al.,2015)	✓	✓	✓		
(Sanchez, L., et. al.,2014)	✓		✓	✓	
(Verma, S., et. al., 2016)			✓	✓	✓
(Bittencourt, L.F., et. al. 2015)	✓	✓	✓		✓

The platform proposed in (Hao et al., 2015) provides a CoAP and generic HTML based IoT Environment for message routing with an analysis of acceptable delays in such systems, but fails to offer on gateway processing capability or any means of static or dynamic load distribution. The solution in (Rathore et al., 2016) provides a polyglot, layered and hierarchical system view where the gateway has only a broker role. The data mining platform from (Chen et al., 2015) provides a higher-level data analysis for metadata extraction and semantics based on their layered app based architecture. The platform from (Sanchez et al., 2014) provides a large scale implemented network that is designed to facilitate future tests on IoT Systems. The proposal in (Verma et al., 2016) provides a way of deploying and managing Virtual Machines in a fog Server Tier. A similar proposal is suggested in (Bittencourt et al., 2015) that looks at high interconnectivity and migration support with device and message abstraction but without a cooperation mechanism.

2.3. Fog Computing

Solving the problem of processing large data-sets on the edge while maintaining some of the capabilities and benefits of cloud systems was attempted by Cisco in (Bonomi et al., 2012) where they proposed the offloading of processing tasks to the edge of the network through Fog Computing. This approach aims to solve some of the latency, security and cost issues with using cloud systems, while improving on the scalability of a private clouds through the pre-processing of data locally.

The distributed control of such Smart Transportation systems has been proposed in (Banks et al., 2018) while (Hou et al., 2016) provides an overview of the addition of vehicles as system nodes forming the Vehicles as Infrastructure initiative. Proposals such as in (Hao et al., 2015) look at Urban planning based on big data management.

Considering these proposals, Fog computing paradigms and approaches are being used to tackle some of the challenges posed by big data management and processing. Furthermore, consideration of scalability and security as well as platform lock-in are also important in similar systems.

3. Vehicular Fog Computing Architecture

When formulating the components and choosing the protocols for the Vehicular Fog Architecture, the main directions, requirements and approaches that were used in the research reviewed in the previous sections need to be considered. One of the most important components that is most often noted in IoT systems is the capability to interconnect devices from different platforms and physical communication backgrounds. To do this our system needs to be able to allow components from different platform to interact using a common protocol or messaging service. The generated messages need to be translated or their protocol specific characteristics need to be abstracted away. These platforms need to be able to do local processing if the direction of Fog computing is to be followed and they need to be able to cooperate through service and resource sharing while allowing the use of these to be improved through either global or load balancing optimization.

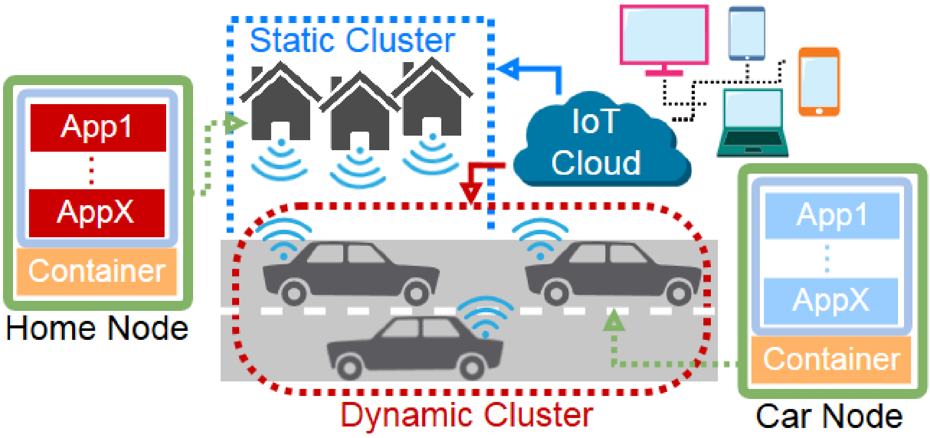

Fig. 1.
Overview of Smart Transportation Platform

Our approach is an extension of the work done in the PaaS approach from (Verba et al., 2017) for such a system that can be seen in Fig. 1. where a high-level view of the system is shown. Here we can see that the proposed Platform design is deployed on each Node on the system, which can be a Home based, Car based, Cloud based, Personal and other types of nodes. When these are considered the main difference between nodes is they mobility. Some nodes are static nodes that either don't or rarely change their location and peer group. The mobile or dynamic nodes change their location constantly as they could be a personal phone, a car, or other vehicles in the system. These varying characteristics are used to create clusters with different interdependencies and connectivity characteristics.
The IoT Cloud connection layer is available to all peers in the system and is designed to allow for higher level data analysis and processing tasks to be run where local information and data is not enough or higher-level decisions need to be made. The cloud layer is designed to incorporate different protocols and link them with the existing analysis and decision systems.

3.1. Fog Platform

The Fog Platform Deployed on all nodes, both static and dynamic have at their core the platform described in Fig. 2. This element relies on the fundamental idea that all components should be accessed in a unified way and the system needs to separate events and control commands that are crucial to transmit from data streams that require high bandwidth but where low reliability and higher latencies are acceptable.

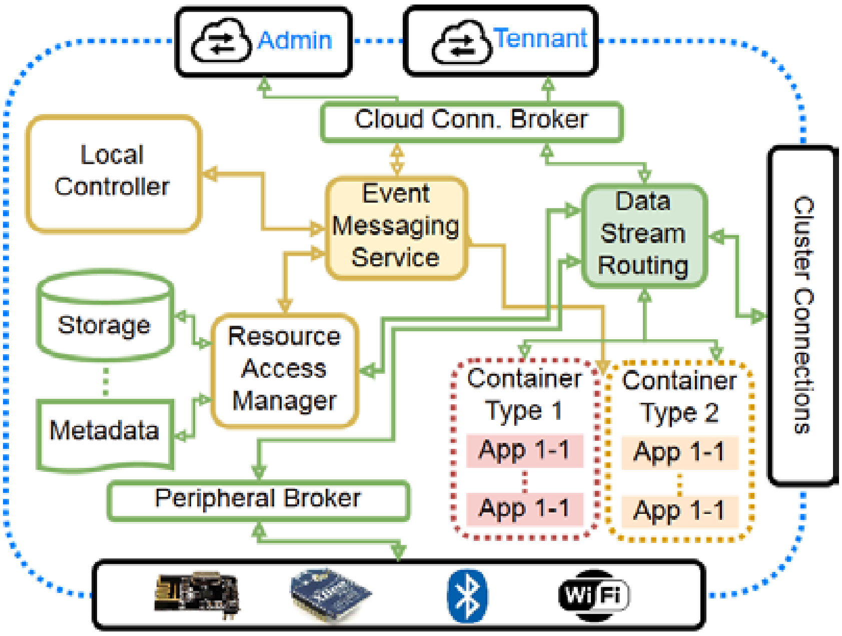

Fig. 2.
Overview of Smart Transportation Platform

The application containers on the system can vary based on use-case and requirements from, VM's to Docker images to Application deployed in shared environments. The main similarity between these is that they will have on message transmission system based on routing to send and receive information to peers. The same thing can be said for the peripheral, cloud and cluster brokers that take local events, messages and data then wrap these into the appropriate format for the sink they are sending it to. The Resource access manager controls the flow of information from apps and other peers to metadata information such as location, signal strengths etc. and varying storages. The local controller receives commands from on-site users and the administrative cloud which it uses to identify peers and control containers, the resource manager and the brokers.

3.2. Cloud Processing Layer

The Admin Cloud layer is tasked with performing centralized control commands on the deployed nodes and providing a user interface where the deployment schematics and system can be viewed. This layer is also tasked with authenticating nodes on the system and between each other. The management of users and region on these nodes is done locally. An overview of this and the tenant cloud layer can be seen in Fig .3.

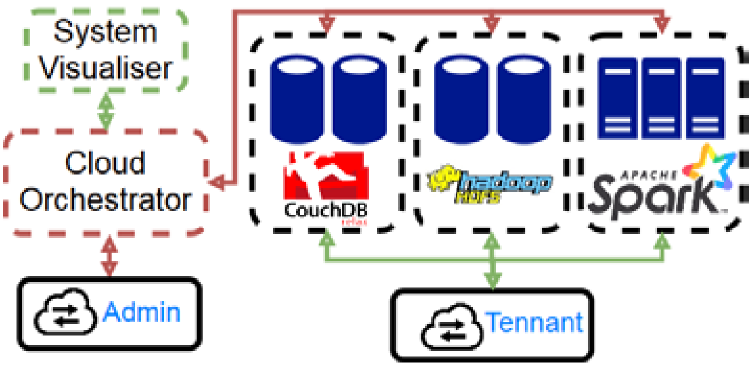

Fig. 3.
Cloud Orchestration and Processing Layer

The tenant cloud layer is designed to link the incoming data from application and nodes to the processing and storage units. The means and parameters of the storage are controlled by the cloud orchestrator which creates the databases and deployed the Hadoop or Spark tasks. This component is also responsible with configuring what happens to the resulting data.
The system visualizer or user interface allows managers and users of the system to have a graph based representation of the application deployed on the system and their interaction. This system aims to show at one time one node with all its applications and resources together with all the applications on other nodes it interacts with. This system aims to show all the apps that are deployed on other nodes but use information from the viewed node as well.

3.3. Clustering and Application Deployment

The creation of clusters and the temporary or permanent addition of peers is central to extending the functionality of IoT systems and realizing the requirements of Smart Cities and Transportation. The mechanism for clustering needs to be able to handle a highly heterogenous set of nodes and varying throughput of devices entering the system. For this to be achieved the authentication system needs to be able to gather information from the system and make decisions based on this. An overview of these phases can be seen in Fig.4.

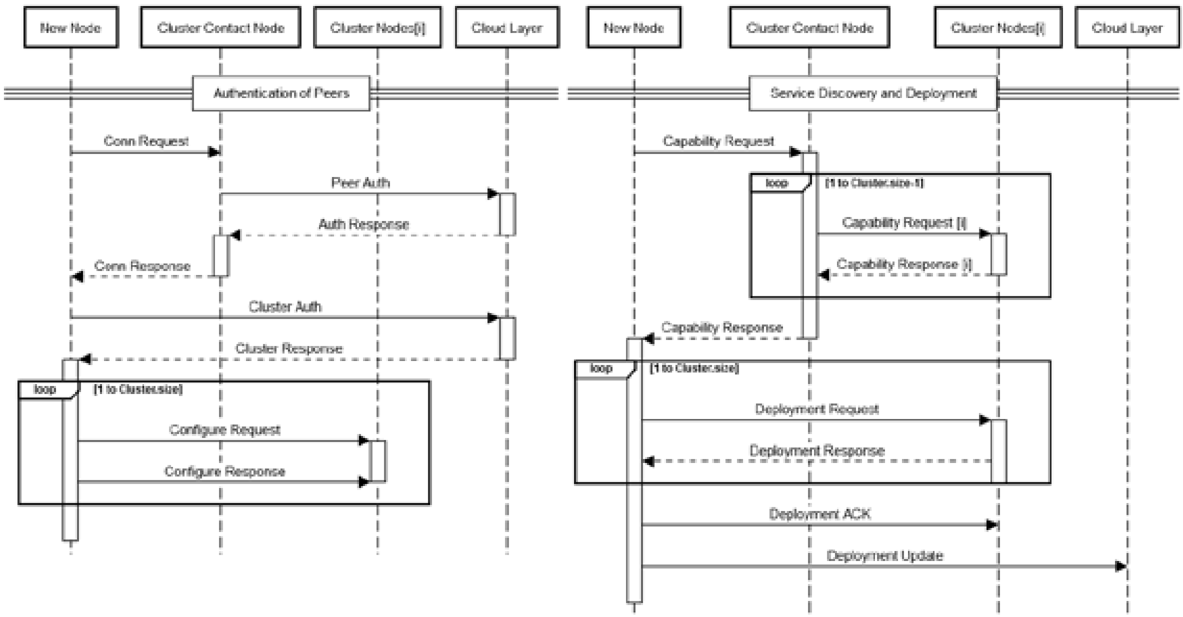

Fig. 4.
Authentication, Discovery and Deployment

The authentication process in based on simple two-way handshake between three entities where the cloud layer is the known and the safe one. The two entities verify each other in relation to the third one. This is done by the new node pushing a connection request to the first node in the cluster it discovered which is assigned a contact role. The contact node takes the information provided by the new node and verifies it through the cloud controller after which sends a response to the new node with the information it needs to authenticate the cluster and join. After the new node has then authenticated the cluster it joins in by sending the appropriate configuration requests to the new set of peers using the peer authentication parameters it received.
The Service Discovery and Deployment phase is designed for a new node to analyse the existing system and determine how it could extend the system functionality and how could the system extend the nodes functionality. The discovery is initiated by the new node by forwarding a request containing its own capabilities to the contact node which then queries the capabilities of its peers and responds to the new node by adding its own details as well. The new node than decides which apps it requires from the cluster and what endpoints and services it is interested in. It then sends the configuration request to each individual node, after which it configures itself. Finally, it sends a cluster wide acknowledgment to the nodes that it has successfully deployed everything after which it forwards and update of the system to the cloud layer.

4. Experimental Setup

The experimental setup is designed to test the functionality of the presented components and to allow us to evaluate how these behave in a real-life system. There were 7 types of devices used in the experimental setup in total. These range from the low capability Arduino and AtTiny based devices to the more powerful Nordic RF52 and to the Raspberry Pi Gateways carrying a varied set of sensors and actuators. An overview of these can be seen in Fig. 6.

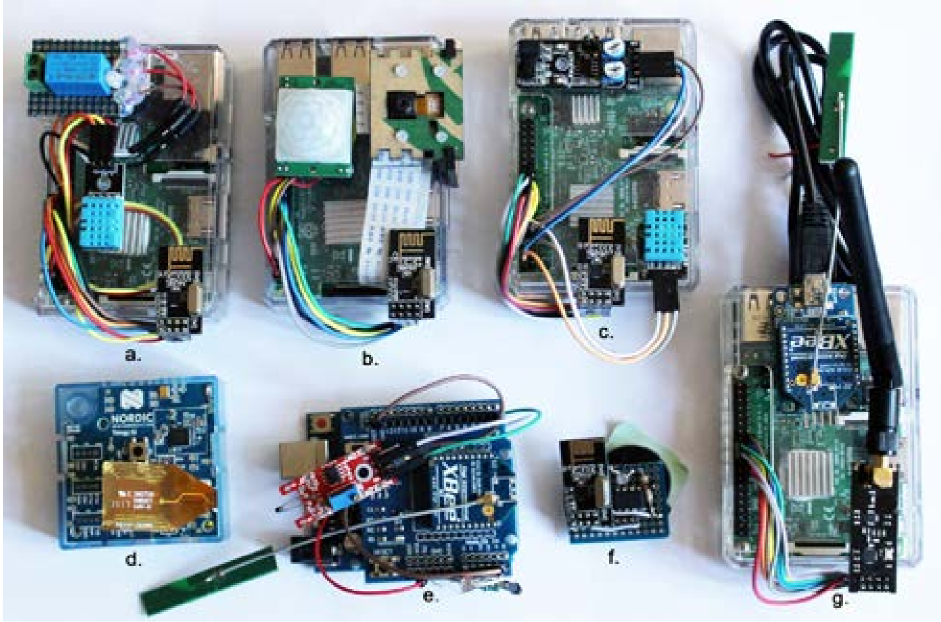

Fig. 6.
Experimental Devices

The Devices from Fig. 6 a,b,c and g are Raspberry pi 2 System on Chip Fog Nodes that have attached varying sensor that allow them to interact with their surroundings. Device a. has a relay, a temperature and humidity sensor and an RF24 wireless transmitter for communicating with peripheral devices. The Raspberry pi from b. is designed to be used with video surveillance, as it has attached a motion sensor and a Video Camera. The device c. has attached the temperature and humidity controller together with the RF24 module as well as a proximity sensor. The node in g. is designed to be a communication hub, as it can send and receive messages in all the testes technologies and has a higher range RF24 device. The device d. is a standard RF52 Thingy node that has a varying set of environmental sensors and communication devices but is used to tests the Low-Power Bluetooth connections with the Raspberry Pi. The XBee enabled Arduino board from e. has a light and temperature sensor for environmental monitoring attached to it. The AtTiny device from f. is designed to be a simple 3.3Volt powered monitoring device.

5. Conclusions and Future Work

The deployment of IoT systems for Smart City scenarios requires a platform that can deal with the scalability and interconnectivity challenges that come from these systems. They need to be able to allow highly heterogeneous application and devices to communicate seamlessly. Furthermore, due to the large computational requirements these systems need to be able to efficiently use the resources available at the edge of the network.
We have reviewed a significant section of the existing work that has been done in the field concluding the requirements and directions. Based on this review we propose a platform that aims to solve these issues using Dynamic and Static clusters based on node characteristics. Furthermore, we propose a dynamic application deployment and updating mechanism for these gateways and an experimental setup for the testing of the deployed systems. The proposed experimental setup looks at providing nodes with highly heterogeneous capabilities, both from the communication, sensor capabilities and use case perspectives.
Our future work will look at large scale deployments of such systems with several dynamic devices that can be attached to the system and evaluation of bottlenecks on the system, how these can be circumvented and the limitations of the clustering approaches. We will also consider the deployment of multiple containers and scenarios using characteristic models from the literature and the optimization of these deployments.

OLDER PEOPLE AND SAFER MOBILITY: HOW CAN INDEPENDENT, MOBILE LIVES BE EXTENDED?

David Morris[1], Eleni Anoyrkati
[1] *Centre for Business in Society, Coventry University, UK*
[2] *Coventry University Enterprises, Coventry University, UK*

Abstract: This paper brings together three major areas which are prone to be seen independently of one another. These are the wide-ranging, ubiquitous and rapidly advancing developments in transport technology; the impacts of a growing ageing population and urbanisation. The interaction between these megatrends forms the broad context against which developments in transport services and mobility must be planned and evaluated. This issue is explored through a consideration of the needs and preferences of older drivers who form a rapidly increasing proportion of the population.

Keywords: ageing society, extending mobility, ICT.

1. Introduction

This paper brings together three major areas which are prone to be seen independently of one another. These are the wide-ranging, ubiquitous and rapidly advancing developments in transport technology; the impacts of a growing ageing population and urbanisation. These "megatrends" are, of course, well known and have been much debated in applied research and policy contexts. However, little research has attempted to bring them together in specific application to older people and their mobility, rather than sustainable mobility in general, and the benefits of extending their active, independent and fulfilling lives through more sophisticated and integrated approaches which exploit new technologies in a targeted way. In particular, how do these trends interact to promote, or, alternatively, place barriers in the way of, extending the mobility of older travellers?

A major challenge will be to devise and implement policies which integrate public and private transport provision in ways which support the creation of portfolios of mobility services which will serve individual needs. The paper takes a broad view of private transport in that it includes private car ownership and use alongside other means of accessing transport and mobility services. The term "private" emphasises the type of access to the car, that is sole use by the owner driver (ownership being taken to cover a wide range of financial arrangements including, for example, leasing), rather than the physical nature of the vehicle itself. Among other sources of evidence, this paper draws on the outputs of recent EU projects where the authors have played significant roles.

2. Megatrends

Megatrends are long-term processes of transformation with a broad scope and a high impact (Georghiou et al., 2009). They are powerful factors which shape markets and drive social change. Megatrends have:

- Long time horizons and can be consistently observed over decades rather than months or years;
- Wide scope; their impact extends beyond geographical borders, and results in multidimensional, interconnected and major drivers for change in politics, society and the economy;
- Intensity of impact; all actors involved are affected robustly and comprehensively, this includes governments, individuals and businesses.

They also affect each other, which can make their impacts unclear and difficult to predict. Megatrends are, nevertheless, useful concepts when assessing the future developments and challenges which promoting mobility and developing the transport system call into play.

OPTIMISM identified megatrends through a comprehensive literature research of key-factors combined with expert knowledge. The identification of megatrends was central to an impact analysis of a wide range of factors influencing mobility and the future transport systems. Transport experts embracing a wide range of perspectives were asked to identify and rank the importance of megatrends as part of an extensive Delphi study. Eleven megatrends were identified. Urbanisation and the growth of cities was ranked as the most important factor influencing future transportation needs. Demographic and social change, including the growth of an ageing society, was ranked eighth and the shift to a knowledge society eleventh.

The INTEND project used a similar methodology to OPTIMISM. The main factors underpinning sustainable mobility were identified from a literature review. This was followed by a Delphi study to which fifty-nine experts drawn from the transport industry, policy makers and academic researchers contributed. Factors were ranked on a five-point Likert scale from 1, "Not at all important", to 5, "Extremely important". The highest scoring factor (mean = 4.41; SD = 0.9) was "Development of large metropolitan areas". The second highest scoring was "Ageing society" (mean = 4.3; SD = 0.79) and the third was "Urbanisation" (mean = 4.2; SD = 0.9). Further analysis of the Delphi questionnaire rankings using ANP (Analytic Network Process; see Saaty, 2001) methods revealed a strong degree of interconnectedness

[1] Corresponding author: d.morris@coventry.ac.uk

between the three factors. ICT developments were not included as a factor in the Delphi study since they did not feature strongly in the literature reviewed (Anoyrkati et al., 2016).

2.1. Ageing Societies

In industrialized countries, the number of older adults has increased and one quarter of the population will be aged 65 or older by 2050.The population share of the elderly over 80 years will be 13% by 2020 in Austria, Germany, Greece, Italy, the Netherlands, Portugal and Spain. In the UK the proportion of retired people is expected to be 23% by 2031. Eurostat statistics predict that the share of people above the age 65 in Europe will grow to 21% by 2020 and 28% by 2050. The impacts of a growing ageing population are raising major questions about how we might extend the active, independent and fulfilling lives of older people and the role of new technologies in helping realise this aim.

Current and future seniors, compared with previous generations, are healthier, wealthier and have a more active life style, including increased travelling and leisure mobility. However, ageing will still have a significant impact on mobility needs and services. Ageing reduces physical mobility and cognitive functions, slows reaction times and limits the capacity to process multiple sources of information simultaneously. The management of older peoples' safe mobility is becoming an increasingly important issue; mobility is vital for their quality of life. "Seniors" are becoming more mobile than in the past and the number of trips per year taken by the elderly has almost doubled (Dejoux V. et al., 2010). However, the older population is increasingly diverse and mobility needs and expectations vary across segments (Marin-Lamellet and Haustein, 2015).

2.2. The Growth of City Living

Approximately 50% of Europe's population lives in cities, and this is expected to rise to 70% by 2050. About half the urban population do not own their own car, but this is particularly marked in the under 30 age group. In addition, the proportion of men in this age group holding driving licenses is falling in many EU countries. The corollary of this observation is, of course, that older people are forming a growing proportion of car owners. Consumers of cars have been hardware-oriented, the physical product was the focus. There is now a growing trend towards a more service-oriented attitude to mobility needs with easy, timely, flexible on-demand access to a seamless provision of transport provision at the fore.

In Europe the level of urbanisation is expected to grow, although at a slower rate. The spatial structures created by urbanisation are determining factors for the mobility and transport sectors. A sufficient supply of mobility services is essential for these densely populated commercial centres with high production and service levels. Problems arise from the concentration of commuter flows during traffic peaks. Appropriate infrastructure also needs to be available, as well as good connections from the centres to the ever more sparsely populated peripheries. The trends of centralisation and the desertion of peripheries are leading to contradictions where the profitability, infrastructure and operations of transport need to fulfil conflicting requirements. Enabling economically affordable equality in accessibility is one of the main challenges.

Europe and Northern America has shown a demand for personal transport where individual mobility is an essential component of everyday life due to separated locations of residential, work and leisure activities (Rudinger et al., 2006). In Europe, at least, just over half of all car journeys are less than 8km in length and 80% are less than 16km. The vast majority of car journeys, over 90% begin and end in the same cities or towns.

The mobility sector will also be heavily influenced by changing household structure. Average household size has dropped by 10-15% and single person households make up a third of the total in many European countries. Again, demand for individual mobility services will increase. Life styles are becoming more versatile, leisure activities are gaining in importance and everyday life becomes more irregular and quickly changing.

2.3. New Technology and the Growth of the Knowledge Society

Knowledge acquisition and use, capacity for innovation and further development of products and services are characteristic of the knowledge economy. The emergence of the knowledge economy as a megatrend has made the acquisition and further development of knowledge necessary for corporations and individuals. The use of information and communication technologies (ICTs) to plan and facilitate the timing and location of day-to-day activities is a key component of emerging activity patterns, especially in urban mobility. One major driver for its development is the need to perceive mobility as a reflection of expanding spatial and temporal choice, and of "on demand" consumption. (Lee-Gosselin M. et al., 2009). According to Lee-Gosselin et al.*a key characteristic of this trend is a ``post-modern" complexity, in which mobility is a reflection of expanding spatial and temporal choice, and of "on demand" consumption.* The trend towards more cooperative transport systems and new types of mobility requires the development of new classes of ICT technologies and better ways to exploit existing ones.

IMTI (Integrated Multimodal Travel Information) applications have dominated transport ICT over the recent past. The main drivers of demand are time (travel and search time) and physical, cognitive, and affective effort savings. The most popular application relates to the pre-trip stage when planning multimodal travel. According to ERTRAC (2009), by 2030, a highly integrated and service driven information society will emerge in which the mobility consumer takes part actively and continuously regardless of his/her location and activity (home, work, commuting, leisure). In urban areas,

where by 2030, more than 80% of the European population is expected to be located, a wide variety of free or low-cost online services will bring on dramatic changes in consumer awareness, attitude and behaviour towards transport in general and personal mobility in particular.
Mobility operators will be able to use the same information services, for example to optimise the efficiency of the network infrastructure, or to limit the environmental impact of mobility patterns, by offering travel incentives to specific consumer groups or to customers on preferred travel modes and routes, or by implementing real-time traffic controls in specific locations. ICT developments will also contribute to the reduction of social exclusion by enabling travellers to have the same access to information and cost-effective mobility options, no matter where they live or how old they are.

3. Older Travellers

In industrialized countries, the number of older adults has increased and one quarter of the population will be aged 65 or older by 2050. In the UK, the number of people aged over 70 holding a driving licence now exceeds five million and, in Denmark, a much higher percentage of drivers aged over 70 intend to keep their licenses than in the past (Siren and Haustein, 2016). The older, affluent motorist sector is expected to grow by 35% between 2015 and 2020. Fourteen percent of the 55-64 age group in the UK have bought a new car in the last two years; the figure for the 65+ group is 11%. These groups have the highest rate of new car purchases in the UK; people over fifty currently buy 65% of all new cars. This demographic pattern is not peculiar to the UK, rather it is a feature of many developed economies.
Population ageing will be accompanied by an increase in the number of older drivers on the roads. Normal ageing results in a decrease in visual, psychomotor and cognitive abilities that are needed in driving. Moreover, older drivers are physically more fragile and vulnerable than younger ones and present a major risk of injury during a road accident. Several traffic situations, such as night driving, driving during rush hour, in bad weather, on motorways or in unfamiliar places, can be stressful or difficult for older drivers. In such cases they may be forced to give up driving or may (probably unwillingly) adopt driving avoidance behaviour triggering social isolation or increased risk of depression.
However, older drivers can adapt their driving behaviour to age-related functional and cognitive decline by avoiding difficult driving situations or by developing compensatory strategies, for example by increasing safety distances, reducing speed or reducing distances traveled. A study of the driving habits of Canadian seniors showed that they were significantly more likely to make social and entertainment trips on days with good weather and out-of-town trips on days with good road conditions (Myers et al., 2011). This behavioural adaptation reflects driving self-regulation, which allows the older driver to continue driving safely despite age-related changes. Of course, not all older drivers self-regulate their driving behaviour; many who do systematically over-estimate their own abilities, a phenomenon known as calibration bias. Drivers with poor cognitive performances and those who are not aware of their own abilities are less likely to avoid difficult driving situations than those with higher performances or have a more accurate view of their own abilities. New technologies can play a major role in mitigating these declining abilities, providing older drivers with tools which will help them drive more safely and longer.

4. The Preference for Cars

The importance of cars as a means of providing transport should not be underestimated. The continued dominance of private motoring for older travellers as a means of accessing mobility services needs to be fully taken into account in transport planning. A significant proportion of travellers prefer cars over public transport, even if public transport is potentially more attractive in terms of costs and travel time. The preference for private ownership is more marked among older drivers than younger ones; 83% of older (>60) drivers in a cross-section of developed countries wanted to own their car (Continental Ag, 2015).
Travellers' positive attitudes with respect to passenger cars are closely related to psychological factors such as feelings of freedom. As Marchetti (1994) put it, *the car has gradually evolved into a personal prosthesis, owning a car and freedom of movement can be considered anthropological invariants in travel behaviour.* Whilst there is significant evidence that this trend may be reversing in some demographic groups, notably younger people resident in cities, the preference for private car ownership is still very strong among older transport users. However, unpacking the Marchetti thesis may be productive. Two aspects may be of particular interest. Firstly, privacy and ownership need to be conceptually separated (Dutzik and Baxandall, 2013). Whilst private car ownership confers control over transport privacy, it may not be the only way of doing so, particularly in a technologically advanced society. For example, car-sharing and privacy may be much more compatible than they were in the past. Private ownership has also been the most effective way of providing personalisation of transport. Again, the development of more flexible, demand driven transport services may help to loosen this tie; mobility may become "smarter". New policies and strategies tailored to meeting the needs and wants of older travellers through the promotion of different private transport modalities are needed. The attractiveness of cars to older buyers needs to be based in driving features and not the form of ownership or access.

4.1. Connected Cars

What makes a car "connected" is the presence of devices in an automobile that connect the devices to other devices within the car/vehicles and or devices, networks and services outside the car including other cars, home, office or infrastructure. The important feature is connectedness. "Connected cars" includes autonomous ("driverless") vehicles (AVs) and ones employing Advanced Driver Assistance Systems (ADAS). The technology which is commonly associated with ADAS, for example parking assist systems and autonomous emergency braking (AEB), is already potentially able to prolong a safe driving career for older drivers. Automation can reduce human (driver) workload leaving more time and attention capacity for driving tasks such as monitoring the environment, identifying potential hazards and predicting changes in traffic. However, there is some evidence that higher levels of automation may be the source of falls in human performance, particularly if over-reliance on systems results in reduced driving skills over time.

Driving cessation provides an instructive and compelling example of the potential benefits of ADAS. Premature driving cessation occurs if driving activity is discontinued at an earlier stage than indicated given the driver's capabilities. There is significant evidence that premature driving cessation is particularly marked among women and that efforts to prevent this should focus on women's confidence and experience in driving (Siren and Haustein, 2016). Driving cessation can be either voluntary or involuntary, although the distinction is not always clear-cut. A study of Baltimore US seniors who had given up driving showed that 83% of respondents had stopped driving by their own decision (Choi et al., 2012), although some of these could also have been premature. A 2016 US review of 16 published studies showed that seniors who stopped driving were more likely to die within 3-5 years than those who did not (Chihuri et al., 2016).

Many driving aids are already familiar; for example:

- Improved safety through better road infrastructure, on-board safety systems, automatic "Smart SOS" emergency services calling (for example, eCall);
- Reduction in incidence and effects of vehicle crashes through collision protection systems;
- Improved vehicle security through more sophisticated access systems;
- Better use of road infrastructure to reduce congestion, enable smart parking and facilitating the spreading of journeys through time through vehicle mobility management systems;
- User and usage based, including driving style and habits, insurance premiums providing an incentive for safer driving;
- Operational assistance such as (adaptive) cruise control and autopilot, parking aids and visibility enhancement;
- Monitoring driver well-being through detecting tiredness and fatigue, contacting medical assistance when appropriate, and adjusting the car's internal environment to mitigate the effects of driver fatigue;
- Providing real-time feedback on driving performance to mitigate the incidence of calibration bias and improve the effectiveness of self-regulation.

Whilst connected cars have received a great deal of attention, we must be wary of concentrating on cars at the expense of people; we should focus on connecting travellers. What makes a traveller "connected" is having real time access to devices that connect to other devices and networks and so provide enhanced access to transport and mobility services, and the home, office or other infrastructure. Technological and other developments in the transport arena can, suitably applied, help older people travel more safely, confidently and securely, and for longer; connectedness enables and promotes different degrees and dimensions of travel autonomy. However, such benefits are not driven solely by technological development, but embrace the societal benefits which result from extending the safe and secure mobile life of an ever-expanding group of ageing travellers. Connectedness enables and promotes different degrees and dimensions of driving autonomy rather than the desire for autonomy in vehicles being the stimulus to develop connected cars.

5. Summary

Securing access to transport services through private ownership of a car is likely to remain the cornerstone of personal mobility for a long time to come. Arrangements such as car-sharing are of growing significance, but are based on a different model of access than private ownership per se. However, we must be wary of implementing change in an unconsidered way, avoiding the temptation of "doing things because we can". Travel-related ICTs are progressing very quickly, outstripping our abilities to keep up in associated ways.

The positive opportunities to improve accessibility and promote mobility for older drivers (Fagnant and Kockelman., 2015; Ticoll, 2015), the greater independence inherent in a longer driving career (Bohm and Häger, 2015) and wider travel horizons (McCarthy el al., 2015) have all been promoted as potential benefits of implementation of ADAS. However, this potential to improve the health and social wellbeing of older drivers is tempered by a possible lack of social acceptance of radical innovations, a lower capacity to accept and master new technologies and lack of capability to benefit from them (Anderson et al., 2014). Economic factors may play a regressive role in the adoption of new technology; those with the greatest need may be over-represented among lower income groups (Bierstedt et al., 2014). The societal, organisational, regulatory and business developments required for success may need to be as radical as the technological ones if we are all to benefit safely, securely and confidently. We must apply technology to mobility rather than simply putting travellers into new technology.

THE FUTURE OF THE EUROPEAN TRANSPORT SECTOR: IDENTIFYING THE KEY TRENDS REGARDING THE TRANSPORT CONCEPTS OF THE FUTURE

Alkiviadis Tromaras[1], Efthymis Papadopoulos[2], Aggelos Aggelakakis[3]
[1,2,3] Centre for Research and Technology Hellas (CERTH), Hellenic Institute of Transport (HIT), 6th Km Charilaou - Thermi Rd., 6th Km Charilaou - Thermi Rd., Thermi, Thessaloniki, 57001, Greece

Abstract: The transport sector plays a significant role in ensuring the competitiveness and sustainable economic growth of Europe. The current transport system remains unsustainable while the EU will have to face major challenges in overcoming global socioeconomic megatrends, technology readiness and adaptation as well as new disruptive transport concepts. The aim of the current paper is to define the term future transport concepts and identify the latter within the context of passenger and freight transport with an outlook of 2020-2050. Thus, a literature review of forward-looking EU research projects and respective industry reports was carried out that identified 25 future transport concepts. Key trends of the aforementioned transport concepts have been identified while further analysis has been carried out to present the transport modes that these concepts are applicable to including their likely timeline of implementation based on the literature. Transport concepts such as automation, shared mobility, seamless transport, electrification, Superfast Ground and Underground Transportation, were found to be key trends among both transport sectors.

Keywords: future transport concepts, future of transport, mobility concepts, transport concepts.

1. Introduction

The transport sector plays a critical role in ensuring sustainable economic growth for Europe, offering jobs, better quality of life of the European citizens as well free movement of goods, services and individuals (EC, 2014). Within this context, the EU has recognised the importance of transport as a basic parameter for its future development and growth, which can provide a competitive advantage at a time of increasing global competition (EC, 2011; CEC, 2012). Despite the fact that, legislative progress is being made to decarbonise and make the European transport sector more efficient, the overall system remains unsustainable. The major challenges facing the European transport sector include traffic congestions, oil dependency, greenhouse gas emissions, infrastructure as well as growing competition from other transport markets (EC, 2014). Furthermore, the current and future global socio-economic megatrends, such as ageing population, urbanization and megacities, changing lifestyles, key resources scarcity, environmental challenges – climate change, will shape the European transportation system even further (Maraš et al., 2018).
In order for the European transport sector to face the current and future challenges, innovative transport solutions as well as research and innovation (R&I) support will be required. The EU considers R&I focused on sustainable, green and smart transport systems as a major and integral part of its transport policy and funds relevant research through various research funding programmes, aiming to keep Europe at the forefront of technological advances in transport (EC, 2014). To that end, a communication was published to provide guidelines for the development of a strategic plan for transport research, innovation and deployment (EC, 2012; Wiesenthal et al., 2015). According to the latest available data, the transport sector (automobiles and other transport) accounted for the largest share (29.8 percent) of EU companies' R&D investments, compared to 18.3 percent in a global scale (Hernández et al., 2017). Additionally, EU companies that reported R&D in the transport sector, provided employment to about 2.9 million people, regarding the aforementioned time period (Hernández et al., 2017).
The European transport sector is in a transitional period and in order to deal with the current and future challenges, a shift away from conventional thinking towards radically innovative ideas is needed (EC, 2012). Several pioneering transport concepts have already emerged and continue to emerge thus presenting a shift towards more disruptive mobility ideas. The latter will cause systemic changes to the transport system whether due to technological advances, political imperatives as well as new emerging transport concepts aiming to enable the European transport sector to effectively address the current and future mobility challenges. The main objective of this paper is to identify key trends regarding the transport concepts of the future in the literature, within a time horizon of 2020-2035 and beyond. The identification of the major trends in terms of future mobility concepts will enable a "sketching" of the way in which people and goods are likely to be transported in the future.

2. Research Gap & Methodology Followed

The methodology that was used to capture the key trends in terms of the future transport concepts involved desk research and specifically two main types of literature: a) forward-looking research projects (covering their project deliverables) and b) forward-looking reports from consultancy companies or industry related view reports including future transport-related technology-oriented websites and private/initiatives. In terms of research project, the literature review consisted of reviewing EU Framework Programme 7 (FP7) and Horizon 2020 funded projects that have already carried out their own analysis of future mobility concepts, to a certain extent (MOBILITY4EU, FUTRE, RACE2050, OPTIMISM, METRIC, iKNOW). For the online research key word terms were used such as "future mobility concepts",

[1] Corresponding author: atromara@certh.gr

"transport concepts", "future X mode (X mode i.e. road, aviation, waterborne, rail) transport", "future of X mode", "innovation in X mode".
Based on the literature review, various transport concepts were identified with a time horizon of 2050. The results were divided into passenger and freight mode and the transport sector that they are applicable to (road, rail, aviation, waterborne). Similar transport concepts were labelled under wider categories that described the same notion. In addition some of the identified concepts were applicable to both passenger and freight sector. Furthermore, the analysis included the transport modes that each concept is applicable to and a timeline for their potential implementation, based on literature predictions and using Short (2020-2025), Medium (2025-2030) and Long term (2030-2035+) scale.
From the analysis of the transport concepts two main matrices (section 5.1 and 5.2) were build that present the key trends for passenger and freight transportation sectors, on the basis of highest number of citations in the literature. The key trends identification was based on the approach taken by the EU INTEND project and Tromaras et al. (2018) that defined a cut-off criterion of the seven top ranked concepts for each transport sector. The resulting key trends are to some extent expected to reflect those mobility concepts that are more likely to shape the future transport landscape. Finally, the concepts that form the key trends were further detailed for the purpose of presenting the level of maturity, the potential implications as well as the key considerations for the further development and adoption of each mobility concept. Fig. 1 presents the main methodology steps that were followed in the completion of the current study.

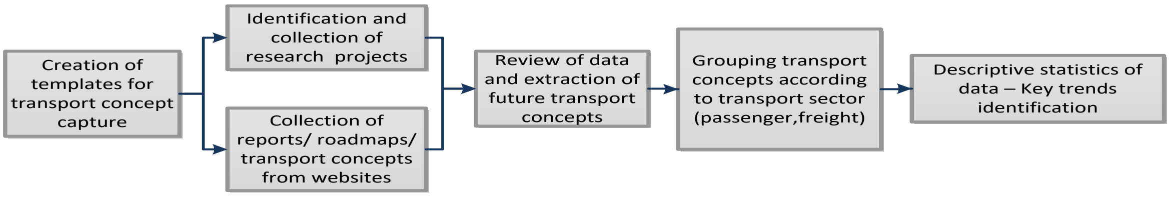

Fig. 1.
Methodology steps followed in the current study

2.1. Transport Concepts – Providing a Definition

Having identified a literature gap regarding the term "transport concept" or "mobility concept", a definition was given that described how mobility takes place between two places, referring to the movement of passengers or goods. It may describe the transportation mean and the way that transportation or mobility takes place. **Table 1** explains the total number of (25) future transport concepts that were captured by the literature review.

Table 1
Total number of future transport concepts captured by the literature review

Transport Concept – Code Name	Transport Concept – Context, Brief Description
Slow Travel / Slow Logistics	Reduced importance of time regarding both passenger and freight transport modern life
Superfast Ground and Underground	Hyperloops, Cargo Tubes, Underground Freight Pipelines (e.g. "CargoCaps")
Personal Rapid Transit (PRT)	Small automated pods or buses operating on designated rails (network of specially built guideways) or on streets, for either scheduled or individual destinations
Magnetic Mobility, Magnetic Levitation	Magnetic levitation technology for rail (maglevs), shopping carts / magnetic shoes sliding on / along magnetic tracks
Personal Air Transportation, "Flying	Urban air mobility; small personal aerial vehicles manually piloted, remotely piloted or fully autonomous
Seamless Transport Chains – Multimodality, Intermodality	Multimodal, intermodal or seamless transport chains for passenger and freight transport
Automation	Autonomous or automated driving for any transport mode for either passenger or freight transport
Noiseless Transport	Noiseless aviation – advanced low-noise aircrafts; reduction of noise and vibration in trains; comfort and noiseless shipping – low vibration vessels; reduction of noise of urban freight
Delivery Drones	Urban airspace utilization for deliveries of goods; delivery drones as a part of the supply chain
Electrification	Electrified transportation means for any mode using electricity, hydrogen fuel cells or hybrid propulsion
Small Vehicles Developed Fit-For-Urban-Purpose	Smaller vehicles, vehicle designs between e-bikes and e-cars, foldable city cars
Smart Use of Travel Time	Use of travel time made available because of vehicle automation; travel time as a usable timeslot for a wide range of activities
Shared Mobility, On-Demand Mobility, MaaS, FaaS, LaaS	Shared ownership models, on-demand mobility; Mobility as a Service – MaaS, Freight as a Service – FaaS, Logistics as a Service – LaaS

Transport Concept – Code	Transport Concept – Context, Brief Description
Private Car Ownership, Luxury Vehicles	Private car ownership remains the norm, continuing appreciation of status symbolism
Seamless Security Checks, Innovative Check - In Processes	Integrated security approach "No Borders"; seamless security checks at airports, innovative check - in processes
Blue Modal Shift	Bringing transport to inland waterways; Short Sea Shipping (SSS) promotion
Co-Modality	Efficient use of different modes on their own and in combination
Freight Consolidation Hubs, Freight Distribution Centres	Urban and peri –urban freight consolidation hub freight villages; multimodal settlements that provide access to different modes of transport as well as several inter-modal infrastructure facilities for logistics service providers.
Urban Cross-Modal Logistics	Urban cross-modal logistics utilizing all transport modes; deliveries with small electric vans, (electric) bikes or tricycles; small and flexible means for road freight transport
Personal Mobility Devices – Micro-mobility	Personal mobility devices, such as Segway, electric skateboards, etc.; reduced usage of traditional forms of mobility for short distances
High-Speed Rail	High-speed train technologies; high-speed rail for passenger transport
Crowd Delivery – Crowd-based City Logistics	Urban deliveries – crowd delivery; involvement of private individuals traveling on a particular route, in urban deliveries
Quite Night Urban Deliveries	Urban deliveries done at night when traffic is limited
Freight Shuttle Systems	Freight shuttle systems for high-volume freight containers; unmanned shuttles propelled by electric, linear induction motors, able to carry cargo on elevated, dedicated tracks (e.g. Freight Shuttle System – FSS initiated at Texas A&M Transportation Institute)
Smart, Dynamic and Interactive Highways	Safer and more sustainable roads; interactive lights; smart energy sources; adaptable to different conditions road signs; photo-luminescent road markings; temperature sensitive warning signs on the road; solar roadways containing heating elements, inductive charging capabilities for electric vehicles, etc.

3. Review of Selected Literature

The analysis of literature was performed in parallel for passenger and freight transport, since the majority of the literature sources dealt with transport concepts applicable to both sectors. Table 2 presents all the future transport concepts drawn, the number of citations in the literature review and their sources.

Table 2
Future transport concepts over literature sources

4. Transport Concepts of the Future in Passenger and Freight Transportation

The following section contains the future transport concepts that were identified in the literature review and have been grouped into passenger or/and freight transport based on which of these categories they were applicable to, according to their source. In some cases these concepts were applicable to both categories. For example, the shared mobility concept was predominantly mentioned in the scope of passenger transportation. Nevertheless, shared mobility is also applicable to the freight transportation sector as well, with some of the literature sources having dealt with ideas such as last mile logistics using MaaS, FaaS and LaaS. In this context, the total number of citations referring to shared mobility concept were accounted to both passenger and freight transport sectors. On the other hand, transport concepts that were only applicable to one transport sector they were only accounted only once i.e. high-speed rail has only been mentioned in the literature within the context of passenger transport.

4.1. Transport Concepts of the Future in Passenger Transportation

Based on the reviewed literature, Table 3 presents the future transport concepts regarding passenger transportation and their total number of citations. The transport modes that each concept is applicable to and a timeline for each concept potential implementation are also presented, with the latter being based on the literature predictions.

Table 3
Future transport concepts for passenger transport

Passenger Transport-applicable Future Transport Concepts	Total Number of Citations	Road	Aviation	Rail	Waterborne	Timeline for Implementation
Automation – Passenger Transport	34	+	+	+	+	Medium term
Shared Mobility, On-Demand Mobility, MaaS	30	+	-	-	-	Medium term
Electrification – Passenger Transport	26	+	+	+	+	Medium term
Seamless Transport Chains – Multimodality, Intermodality	20	+	+	+	+	Long term
Personal Air Transportation, "Flying Cars", "Flying Taxis"	15	+	+	-	-	Medium term
Smart Use of Travel Time	13	+	-	-	-	Medium term
High-Speed Rail for Passenger Transport	9	-	-	+	-	Medium term
Superfast Ground and Underground Transportation, Hyperloops	9	-	-	+	-	Long term
Personal Rapid Transit (PRT)	8	+	-	+	-	Short term
Small Vehicles Developed Fit-For-Urban-Purpose	7	+	-	-	-	Short term
Private Car Ownership, Luxury Vehicles	5	+	-	-	-	Medium term
Noiseless Transport	5	+	+	+	+	Long term
Blue Modal Shift	4	-	-	-	+	Medium term
Personal Mobility Devices – Micro-mobility	4	+	-	-	-	Short term
Magnetic Mobility, Magnetic Levitation	3	+	-	+	-	Medium term
Seamless Security Checks, Innovative Check - In Processes	3	-	+	-	-	Medium term
Co-Modality	3	+	+	+	+	Long term
Slow Travel	2	+	-	+	+	Long term
Smart, Dynamic and Interactive Highways	2	+	-	-	-	Long term

4.2. Transport Concepts of the Future in Freight Transportation

The same principles with the previous section were applied for freight transport. The future transport concepts related to freight transportation, their total number of citations, the transport modes that these concepts are applicable to as well as a timeline for their potential implementation, are presented in the Table 4 below.

Table 4
Future transport concepts for freight transport

Freight Transport-applicable Future Transport Concepts	Total Number of Citations	Road	Aviation	Rail	Waterborne	Pipeline	Timeline for Implementation
Shared Mobility, On-Demand Mobility, MaaS, FaaS, LaaS	30	+	+	+	+	N/A	Medium term
Seamless Transport Chains – Multimodality, Intermodality	20	+	+	+	+	N/A	Long term

Automation – Freight Transport	18	+	+	+	+	N/A	Medium term
Electrification – Freight Transport	18	+	+	-	+	N/A	Medium term
Delivery Drones	10	-	+	-	-	N/A	Short term
Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines	9	+	-	+	-	+	Long term
Freight Consolidation Hubs, Freight Distribution Centres	7	+	+	+	+	N/A	Medium term
Urban Cross-Modal Logistics	5	+	-	-	-	N/A	Medium term
Noiseless Transport	5	+	+	+	+	N/A	Long term
Blue Modal Shift	4	-	-	-	+	N/A	Medium term
Crowd Delivery – Crowd-based City Logistics	3	+	-	-	-	N/A	Short term
Quite Night Urban Deliveries	3	+	-	-	-	N/A	Short term
Co-Modality	3	+	+	+	+	N/A	Medium term
Slow Logistics	2	+	-	+	+	N/A	Long term
Freight Shuttle Systems	2	+	-	+	-	N/A	Long term
Smart, Dynamic and Interactive Highways	2	+	-	-	-	N/A	Long term

5. Key Trends Identification and Further Analysis

For the identification of the key trends, a cut-off criterion was needed to be defined in order to reach a certain level of consensus to those concepts with a significant potential to be implemented and to drive disruption and reshaping of the future transport ecosystem. As stated in the methodology the seven top ranked concepts for each category have been identified as the key trends.

Based on the aforementioned principles, the key trend future transport concepts for passenger transport are: *1) automation, 2) shared mobility, on-demand mobility, MaaS, 3) electrification, 4) seamless transport chains – multimodality, intermodality, 4) personal air transportation, 5) smart use of travel time, 6) high-speed rail, 7) superfast ground and underground transportation*.

The respective key trends for freight transport are: *1) shared mobility, on-demand mobility, MaaS, FaaS, LaaS, 2) seamless transport chains – multimodality, intermodality, 3) automation, 4) electrification, 5) delivery drones, 6) superfast ground and underground transportation, 7) freight consolidation hubs, freight distribution centres*.

Automation has been identified as a key future transport concept that is expected to revolutionize transportation for both passenger and freight sectors. Many automakers are currently working on autonomous vehicles while low levels of automation has already been introduced into conventional vehicles. Fully autonomous cars are estimated to become commercially available in the market by 2025-2035 (ERTRAC, 2017). Similarly, in the road freight sector, highway platooning and highly automated trucks on open roads could become available with the aforementioned timeline (ERTRAC, 2017). In the rail sector, automation already exists in selected market segments, such as metro transport, with the example of Copenhagen's metro (Copenhagen metro, 2018) offering full autonomy over specific lines. However, automation remains rare for the main rail lines, while demonstrators are planned for 2020-2025 that will take the current system in Europe towards full autonomy (Shift2Rail, 2015). In the waterborne sector, ship autonomy is expected to reshape the sector with key driving factors being reduction of labour and operating costs, as well as optimized commercial flexibility as a result of big data (Lloyd's register, 2017). Smaller crewless vessels have already been developed and are currently in service, while larger vessels are under development and will potentially be in service between 2020 and 2025 (Paris, 2017; Rolls Royce, 2017). In the aviation sector automation technologies are already being introduced in conventional aviation and smarter avionics systems are being integrated in the cockpit. The main drivers for further automation include increased safety levels, increased throughput, effectiveness and cost efficiency (Voege, 2016).

Fuelled by the shared economy model and boosted by the availability of new communication technologies, shared mobility is rapidly gaining popularity, with several platforms globally being introduced (Whim, UbiGo, Qixxit, Moovel, Beeline, SMILE; Goodall et al., 2017). According to Schiller et al. (2017), Europe accounts for about 50 percent of the global car-sharing market, while the total number of car-sharing users is expected to rise up to 15 million by 2020. Taking into account the suggested rise of shared mobility schemes in the future, the next step will be their integration under one roof, a vision that essentially describes MaaS concept. The MaaS concept also extends to freight transport, with concepts of its use for last mile logistics or other variations such as FaaS or LaaS. Future Transport 2056 (2018) defined FaaS as "a business model whereby on-demand and ride-sharing concepts formulate different procedures for the supply of goods to customers, which is accessed through a single account and booking interface". Furthermore, based on the cooperation of shippers, retailers and delivery companies, LaaS "enables individuals to choose their own logistics service provider and bundle deliveries as they wish, instead of being delivered by the logistics service provider of their online retailer" (MOBILITY4EU, 2016b; Keseru et al, 2016).

Electrification is one of the most commonly referred transport concepts with a potential application across all the transport modes. Electromobility is considered a key enabler for decarbonisation and is in fact already being used and will continue to further penetrate each market at a different pace. For road passenger transport, the global number of electric vehicles (EVs) surpassed 2 million in 2016, with passenger cars, vans and buses already in service. The OECD/IEA (2017) forecasts projected EV car fleet growth to reach 9-20 million by 2020 and 40-70 million by 2025, based on automakers' production pledges. Furthermore, Fuel Cell Electric Vehicles (FCEVs) are expected to contribute to 30 percent of the vehicle mix by 2030 (IEA, 2010), with some models already available in the passenger transport market. Electric trucks and vans are being used by various companies for delivery, logistics and other purposes (Margaritis et al., 2016), while companies like Tesla (Tesla, 2018) and Cummins (Cummins, 2017) are working on heavy duty truck applications. In the rail transport sector, electrification has already penetrated to a great extent. In Europe, 60 percent of the main lines are already electrified and 80 percent of traffic is running on these lines (Meyer, 2016). Although, electrification can have environmental benefits, the cost of upgrading current infrastructure could be an obstacle. Additionally, hydrogen fuel cells have already been introduced in rail, with more recent examples of their usage by Alstom (Alstom, 2017) and Siemens (Railway Technology, 2018). ERRAC (2016) suggests that the use of hydrogen fuel cell electric propulsion in rail will require further development including hydrogen production and storage technologies with a timeline of implementation reaching beyond 2035.

In the waterborne sector, electrification of auxiliary systems or auxiliary electric propulsion is not uncommon. Around 2,500 ships in the world are powered by electric propulsion using diesel electric, hybrid systems or batteries (Meyer et al., 2016). Fully electric ships using batteries exist in small numbers, while recently the first all-electric cargo ship has been launched in China (Meyer et al., 2016; Leary, 2017). Similarly, Hydrogen Fuel Cells in the waterborne sector, can either find applications in providing power to auxiliary systems or to propel smaller as well as larger vessels. For the aviation sector, electric propulsion could be a viable option in the future although, only for short range (Meyer et al., 2016) and it is predicted to be applicable for aircrafts with less than 100 seats (Malkin et al., 2016). Various concepts of small electric or hybrid electric aircrafts are being developed by Airbus, Boeing, NASA, Rolls-Royce and Siemens as well as Embraer (AIRBUS, 2017; NASA, 2016; Embraer, 2018).

Seamless transport chains were identified as another key transport concept of the future, applicable to both passenger and freight transport. E.C. (2011) and OECD/ITF (2012) both highlighted the importance of seamless door-to-door mobility for passenger and freight and recognized seamless transport as a crucial and ambitious strategic vision for the future of transportation. The key topic areas for discussion about seamless transport chains concept implementation, are focused on seamless transport for trade and growth, new approaches for seamless logistics, connectivity enhancement across borders, integration of transport and communication systems to provide seamless services, the role of e-ticketing, smartphones and data sharing in seamless transport provision, etc. (OECD/ITF, 2012). From an IT point of view, ERRAC (2016) suggests that seamless transport travel will be enabled by 2025.

"Flying cars" or "passenger drones", seem to be concepts that are receiving a lot of attention, driven by the rapid technological advances on unmanned aerial vehicle (UAV) technologies. Some typical examples, include CityAirbus, Vahana, PopUp, Ehang 184, Volocopter 2X, Lilium and Uber Elevate (UKi Media & Events, 2018; Lineberger, 2018). Morrell (2017) considered that passenger drones are likely to reach the technology readiness levels of commercialization and adoption before 2030. Over the coming decades, delivery drones are also expected to become an integral part of the supply chain, covering delivery needs in urban and in rural – hard-to-reach areas, thus offering faster delivery times for consumers, less traffic congestion and emissions reduction and increased access of remote areas. Several companies, such as Amazon, Google, Alibaba, UPS, DHL and Wal-Mart have already started experimenting with such systems and the key considerations for the further development and adoption of this concept, include functionality, legislation, system integration into the existing urban infrastructure, safety, security and privacy related issues (Zickuhr et al. 2016, Gulden T. R., 2017). SESAR JU (2016) has forecasted that 70.000 drones could deliver about 200 million lightweight parcels across Europe in 2035.

Being inextricably linked to autonomous driving, smart use of travel time appeared to be among the key transport concepts of the future. In the future, travel time may be seen as a usable timeslot for a wide range of activities, from working, to online shopping, or other in-vehicle entertainment services. Significant revenue opportunities for companies operating in different sectors will emerge, such as services and product sales, on-board advertising, subscriptions, data monetization based on media consumption, (Manyika et al., 2013; Arbib et al., 2017; Corwin et al., 2015).

High-speed rail has also proven to be one of the key future transport concepts relevant to passenger transport that will allow medium-distance passengers to travel by rail offering a cheaper, greener and more sustainable alternative to air and road transport. Several European countries have already developed extensive high-speed rail networks, while some cross-border high-speed rail links also exist. According to EC (2011) a complete European high-speed rail network is expected by 2050 and a stepwise tripling of the length of the existing high-speed rail network by 2030 while connections between all core network airports to the rail network and preferably to high-speed rail will have to be prioritised.

Along the lines of new innovative concepts, superfast ground and underground transportation is likely to play a significant role for future passenger transport. Examples like Hyperloop have been proposed as a faster and more cost-

efficient transport alternative to air and high-speed rail transportation, in respect to distances up to 1.500 km (Musk, 2013; UKi Media & Events, 2018). Despite the main concerns regarding its technological and financial viability, experimentation and testing is underway with Virgin Hyperloop One that aims to provide Dubai with the first Hyperloop system by 2021 and TransPod that is focused on building a Toronto-Montreal hyperloop (UKi Media & Events, 2018). Respectively, underground freight pipelines form another innovative new type of transport infrastructure similar to hyperloop. This concept refers to the use of dedicated pipeline networks for transporting goods underground. Typical examples are the CargoCap and the Cargo sous terrain (CST) concepts, which entail the transport of goods in dense urban centres (CargoCap, 2018; Cargo sous terrain, 2018).
Infrastructures dedicated to freight deliveries in urban areas, namely freight consolidation hubs and freight distribution centres, were the final key transport concept that has been identified. Cities and private companies will have to establish consolidation and freight distribution centres in an effort to improve efficiency, shifting the distribution of freight to inner city utilizing greener and more efficient transport modes (Keseru et al., 2016). Future consolidation centres will bring together flows of goods for entire cities or regions, while different suppliers will have to cooperate and ship together their products via single shippers in an effort to make transport cheaper and more efficient and reduce number of deliveries (Siemens, 2011). IT systems and automation will play considerable role in this endeavor.

6. Conclusion

The current paper presented future transport concepts for passenger and freight transport that have been identified with an outlook of 2020- 2050 after a though review of pertinent literature covering forward-looking projects and industry reports. A literature gap has been identified thus leading to define the term future transport concepts, although the notion of the latter is not unknown when referring to how people or goods are transported. Some of these transport concepts could lead to systemic change of the current transport system and in many cases will cause disruptiveness. An extensive list of future transport concepts has been presented and a consensus was reached in order to identify the key transport concepts that have been cited the most across the literature and have the most potential of being implemented. While, specific concepts are more relevant to the passenger or freight sector, i.e. personal air transport or delivery drones, other concepts share common ground. Concepts such as automation, shared mobility, seamless transport, electrification, Superfast Ground and Underground Transportation, were found to be key trends for both sectors. The difference between them remains their context and how they will be implemented in each case. Compared to previous decades many new innovative transport concepts are being proposed and could potentially become commercially available in the distant future especially in the field of personalised transport.
As most of key aforementioned future transport concepts are already in development and to some extent their technologies are available although not matured enough, the EU will have to identify streams of research in order to prepare for their further development and potential adaptation. The latter does not only depend on technology readiness but also on socioeconomic megatrends as well as political incentives.

Acknowledgments

The results incorporated in this paper received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 769638, project title: INtentify future Transport rEsearch NeeDs (INTEND).

EVALUATING MEGATREND IMPACT ON THE TRANSPORT CONCEPT OF THE FUTURE USING AN ANALYTIC NETWORK PROCESS

Mirjana Bugarinović[1], Vladislav Maraš[2], Eleni Anoyrkati[3], Aleksandar Radonjić[4]
[1,2,4] *University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, 11000 Belgrade, Serbia*
[3] *Coventry University Enterprises Ltd, Puma Way, Coventry, CV1 2TT, United Kingdom*

Abstract: The motive of this research is the fact that until now no universal model for evaluation of megatrends, political imperatives, and technological advances impact on the transport concept of the future (TCF) has been defined. In the process of modeling, megatrends are one of the key elements for selection of the TCF. In this paper is proposed a model for selection of TCF based on the Analytic Network Process (ANP) approach. The developed model has allowed assessing the impact of the megatrends on the TCF and stability of the TCF ranking. It is developed ANP network for the passenger and freight transport separately. Based on the results of research, network structure of the ANP method can successfully resolve the dependence and conflicts among evaluation elements for TCF selection. The proposed ANP based model can become a tool for the evaluation of the TCF and for policy makers making decision. The paper is based on data from the INTEND project.

Keywords: megatrends, transport concept of the future, validation, making decision, ANP, research needs.

1. Introduction

In the last ten years there were huge advances in future studies and in detecting trends methodology, in particular in Europe. New scientific methods for strategic long term planning were developed in the context of long term political planning, participatory democracy and shaping the future with RTI policy initiatives. A trend is usually based on linear pattern, which only work in a specific context. Trends are usually described by time horizon, impact and geographical coverage.
But in reality it is needed to set up a comprehensive knowledge logistics process to integrate the knowledge derived from forward-looking projects have looked at the megatrends. Changes in climate and availability of strategic resources, as well as digitalization and globalization cause a need for proactive adoption and preventive innovation management. Global warming and the dependence on oil will induce revolutionary changes in the industry.
From the other side policies are shaping day-to-day and future mobility by impacting the transport system itself, or influencing mobility framework conditions. Policies and their imperatives are among the crucial factors shaping the transport market. Via direct regulation or via defining market rules, those policies address future transport concepts and technologies.
Having all this in mind the evaluations of the megatrend is challenging as transport itself is a complex environment. The results of the review of relevant and available literature for megatrends (Maras *et al.,* 2018), political imperatives (Doge *et al.,* 2018) technological advances (Tromaras *et al.,* 2018), showed that their number is significant and to assess their impact it is necessary to systematically approach the assessment of their effects on transport concepts of the future (TCF). The systemic approach also means taking into account the limitations of human reasoning. Human thinking has limitations regarding the simultaneous use of data, or when their number is significant. In cases where a significant amount of data is used in the assessment and evaluation process at the same time, due to the inability of the human brain to follow it simultaneously, it is possible not to make useful solutions and decisions (Saaty, 2001).
As megatrends, together with socio-technical shifts in the transport industry, are expected to change the whole sector fundamentally, they should be further validated in order to estimate their impact on defining the future transport concept as research priorities. The aim of the validation process is to determine the prioritized megatrends (as well as technological advances and political imperatives) for successful implementation and realization of key transport concepts of the future.
This paper presents one of the results of the H2020 project INTEND - Identify future Transport Research Needs (grant agreement No 769638, 2017-2018). The overall objective of the INTEND project is to deliver an elaborated study of the research needs and priorities in the transport sector utilizing a systematic data collection method. In this paper, the focus is on one of the project objectives such as to define the megatrends impact on research needs.
After the introduction, the ANP networks for TCF selection are presented in section 2. The numerical results and sensitivity analysis are shown in Section 3 and 4. The conclusion is given in the last chapter.

2. Modeling ANP Network for TCF Selection

The evaluation of megatrend impact is carried out through the application of the Analytic Network Process (ANP). The Analytic Network Process ANP (first papers Saaty, 1996, 1999), represents a decision-making method which enables to present the dependence and feedback between elements, analyze the interaction between them as well as to synthesize their mutual influences through a network structure. This is a method that is used to determine priorities based on the

[1] Corresponding author: mirab@sf.bg.ac.rs

relative relationship between elements, which is a natural procedure for the human mind. ANP model combines advanced decision techniques and expert knowledge.

For the problem of estimation megatrends impact on the transport concepts of the future ANP method taking into account clusters of megatrends, political imperatives, technological advances and TCF. These clusters can be considered as drivers for the future development of both European and global transport system and therefore relevant for the identification of future transport research priorities. How the structure of the ANP network was developed?

First, a sophisticated Limesurvey was used for systematic data collection and define key elements in clusters and relationship between them. Experts were invited to participate in a survey session and ninety responses were received. Principal components analysis as a variable-reduction technique was used to reduce a broader set of proposed megatrends, political imperatives and technological advances (called as elements) into a smaller one, which accounts for most of the variance in the original set of elements. Finally, the 13 key elements which are most likely to impact the future research needs and priorities per transport sectors were identified (Table 1)

Table 1

Key elements that impacts on the future research needs and priorities

No	Passenger transport Sector		Freight transport sector	
	Cluster	**Element**	**Cluster**	**Element**
1	Megatrends	Environmental challenges – climate change	Megatrends	Environmental challenges – climate change
2	Megatrends	Urbanization and megacities	Megatrends	Urbanization and megacities
3	Megatrends	Ageing society	Political imperatives	Vehicle efficiency
4	Megatrends	Energy demand and sources	Megatrends	Bigger world economy
5	Political imperatives	Innovative research system	Megatrends	Energy demand and sources
6	Megatrends	Changing lifestyles	Megatrends	Ageing society
7	Technological advances	Infrastructure	Political imperatives	Innovative research system
8	Political imperatives	Vehicle efficiency	Technological advances	Infrastructure
9	Technological advances	Automation	Technological advances	Automation
10	Political imperatives	Increasing connectivity, intermodal access, and fit-for-purpose network standards	Megatrends	Changing lifestyles
11	Political imperatives	Closer public and private cooperation	Political imperatives	Raising investment in infrastructure development
12	Political imperatives	Supporting modal shift	Political imperatives	Digitisation strategy/regulations/markets
13	Technological advances	Electrified vehicles/vessels	Political imperatives	Closer public and private cooperation

The dominant TCF identified by the studies review (MOBILITY4EU, FUTRE, RACE2050, OPTIMISM and METRIC) are the elements of the TCF cluster. It is identified seven TCF for passenger and eight for freight transport. The TCF are ranked according to their frequency of occurrence in the reviewed literature. Elements in the clusters for TCF for passenger and freight transport are given in table 2.

Table 2

Dominant passenger and freight transport concepts of the future

Transport concept of the future	
Passenger transport sector	**Freight transport sector**

Automation – Passenger Transport (autonomous cars, aircraft, trains, vessels)	Shared Mobility, On-Demand Mobility, MaaS, FaaS, LaaS
Shared Mobility, On-Demand Mobility, MaaS	Seamless Transport Chains – Multimodality, Intermodality
Electrification – Passenger Transport (electric cars, trains, aircrafts, vessels)	Automation – Freight Transport (autonomous trucks, trains, vessels)
Seamless Transport Chains – Multimodality, Intermodality	Electrification – Freight Transport (electric trucks, trains, aircraft, vessels)
Personal Air Transportation, "Flying Cars," “Flying Taxis”	Delivery Drones
Smart Use of Travel Time	Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines
High-Speed Rail for Passenger Transport	Freight Consolidation Hubs, Freight Distribution Centres
Superfast Ground and Underground Transportation, Hyperloops	

Further, the analysis includes relationships among those key elements. Considering the equal number of identified key elements (13) in both transport sectors, there is an equal number of possible relationships among them (78 per transport sector). Forty-eight sets of judgments matrices were generated after the analyzing the relationships between key elements and selected transport concepts of the future. Two ANP networks were identified. The first one is the ANP network used to evaluate TCF in passenger transport and the second one is for the evaluation of TCF in freight transport (Figure 1 and 2).

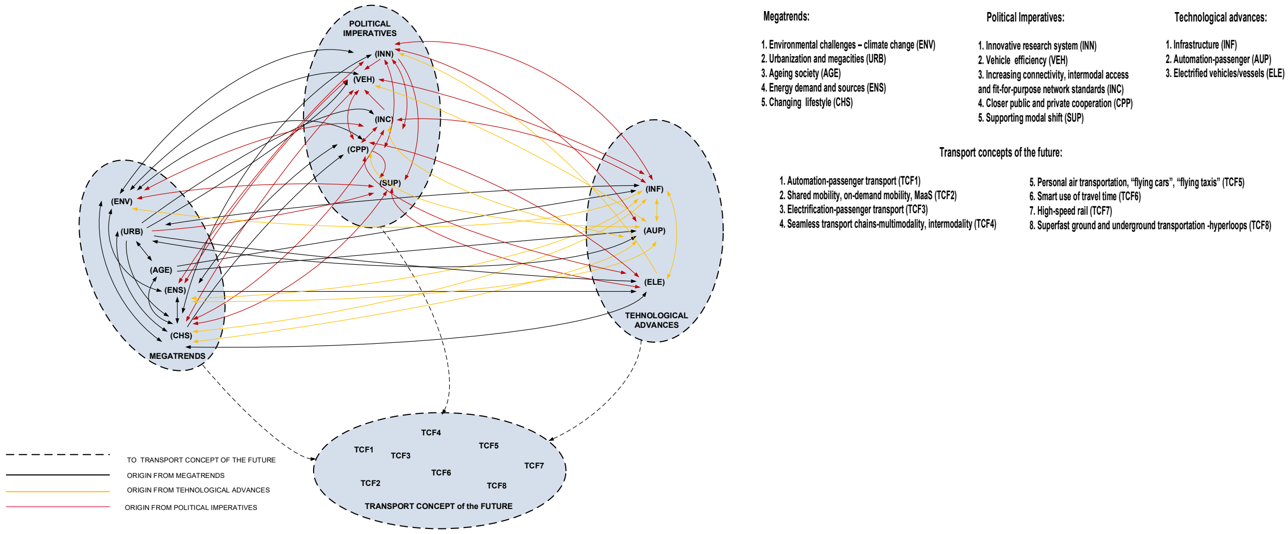

Fig. 1.
ANP network for passenger transport

The application of ANP also required estimation of relationships (weights) between all elements in clusters and between the clusters. Therefore, after the network model has been constructed, the elements in one cluster (e.g., megatrends or advances or imperatives) were evaluated according to their relative importance, through pair-wise comparison, with respect to the elements in other clusters. Further, cluster of key TCF was evaluated according to its relative importance by pair-wise comparison, with respect to other elements in the network.
An evaluation of these relationships was based on an ANP questionnaire survey. The obtained sets of judgments matrices were analyzed by using appropriate software developed by FTTE’s[2] on Python programming language and supported by the ANP Graphical user interface (GUI) application. Based on this analysis, the evaluation of key TCF was gained. It means that after the evaluation of preferences among the different megatrends, technological advances and political imperatives have been done and once the weights have been defined, we determined the prioritized elements (megatrends, technological advances, and political imperatives) in all clusters for successful implementation and realization of key TCF.

[2] FTTE – Faculty of Transport and Traffic Engineering

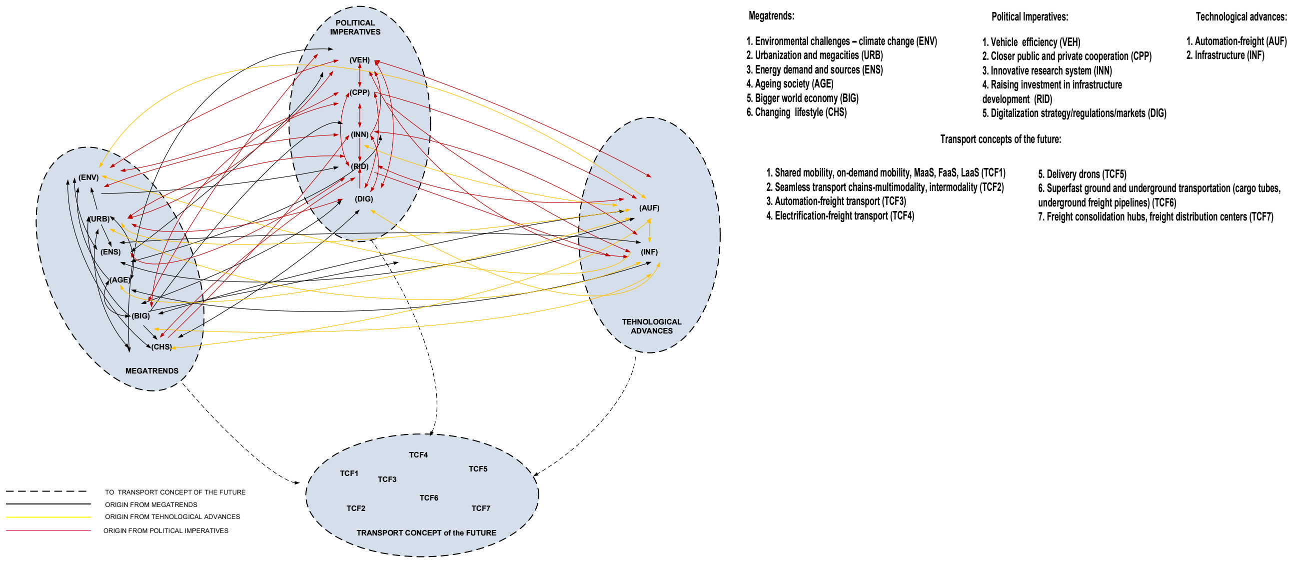

Fig. 2.
ANP network for freight transport

3. Results and Discussion

The megatrends validation has been carried out through the discussion of the results in two ways: (1) an analysis of the priorities of all elements within the TCF and (2) by analyzing the diversity and similarity of the priorities of the elements within the cluster megatrends, political imperatives, and technological advances. This is conducted for passenger and freight transport separately.

3.1. The Priorities of all Elements within the TCF and Megatrends for Passenger Transport

The final priorities for the passenger transport concept of the future (TCFPs) and the priorities of megatrends, political imperatives and technological advances are presented in Table 3. Outcomes are arranged in four groups. The first group of outcomes/results is the priorities of TCFPs. Then a set of priorities for megatrends, political imperatives and for technological advances are followed. For each of these groups is given, a rank in relation to the best-ranked element (Ideal), the normalized priority as a share of the element in relation to all elements in the group (Normalized by cluster), and the Score. It can be noticed that the elements with the highest priority are:

1. High-speed rail in the group of TCFP with 15.99% of overall priorities;
2. Changing lifestyle megatrend with 35 % influence on the TCFPs ranking;
3. Closer public and private cooperation, as political imperatives, with 23.42% influence;
4. Electrified vehicles/vessels, as technological advances, with 41.51% influence.

Looking in detailed we can see that the highest priority value of TCFP has High-speed rail. Looking ahead, the second, third and fourth TCFP is very close to the first one, and these are Personal air transportation, Automation, and Electrification. The other four TCPFs can be grouped into two groups, namely the fifth and the sixth TCFP respectively the seventh and eighth TCFPs. According to the differences between the priorities value of the first four TCFPs all of them can be taken into consideration in future research.
When it comes to elements influences within the cluster megatrends, political imperatives and technological advances all respondents estimate that the most important elements are: Changing lifestyle, Closer public and private cooperation and Electrified vehicles/vessels.
Significantly stands out the influence of the megatrends Changing lifestyle and Environmental Challenges compared to other megatrends. Impacts of these megatrends for the TCFPs are 35% and 30.1%. In contrast to them, the impact of megatrends Ageing society and Urbanization and megacities are smaller and similar values of priorities.

Table 3
The elements with their priorities and ranking for passenger transport

Elements	Ranking	Ideals	Normalized By Cluster	Score
TCFP				
Automation	3	0.8682	0.1388	0.0459
Electrification	4	0.8543	0.1366	0.0451
High speed rail	1	1.0000	0.1599	0.0528

Infrastructure	2	0.8231	0.3417	0.0735

3.2. The Priorities of all Elements within the TCF and Megatrends for Freight Transport

The resulting final priorities (Table 4) for freight transport are obtained by estimation elements and relationships in ANP network for freight transport. The elements with the highest priority are:

1. Automation as TCFF with 20.87% normalized priority;
2. Changing lifestyle megatrend with 28.4% influence on TCFFs ranking;
3. Digitalization strategy/regulations/markets, as political imperatives, with 24% influence;
4. Automation in freight transport, as technological advances with, 60.6% influence.

Focusing on the priorities of TCFFs we can see that the Automation is dominant. TCFF Delivery drones and Shared mobility ranked second and third, are with a significant difference in priority value compared to Automation. All other TCPFs can be clustered into two groups, and the last group consists of Seamless transport chains and Superfast ground that representing business platforms.

When it comes to elements influences within the group's megatrends, political imperatives and technological advances the most important elements per groups are: Changing lifestyle, Digitalization strategy/regulations/markets and Automation in freight transport. The importance of Changing lifestyle megatrend suggests that the change in the lifestyle generates new and in the transport of goods different demands for transportation, or different supply and demand. In contrast to them, the impact of megatrends Bigger world economy and Ageing society are with small impact.

Table 4

The elements with their priorities and ranking for freight transport

Elements	Ranking	Ideals	Normalized By Cluster	Score
TCFF				
Automation	1	1.0000	0.2087	0.0744
Delivery drones	2	0.7635	0.1593	0.0568
Electrification	5	0.6468	0.1350	0.0481
Freight consolidation hubs	4	0.6592	0.1376	0.0490
Seamless transport chains	6	0.5669	0.1183	0.0422

Automation-freight	1	1.0000	0.6062	0.0846
Infrastructure	2	0.6496	0.3938	0.0549

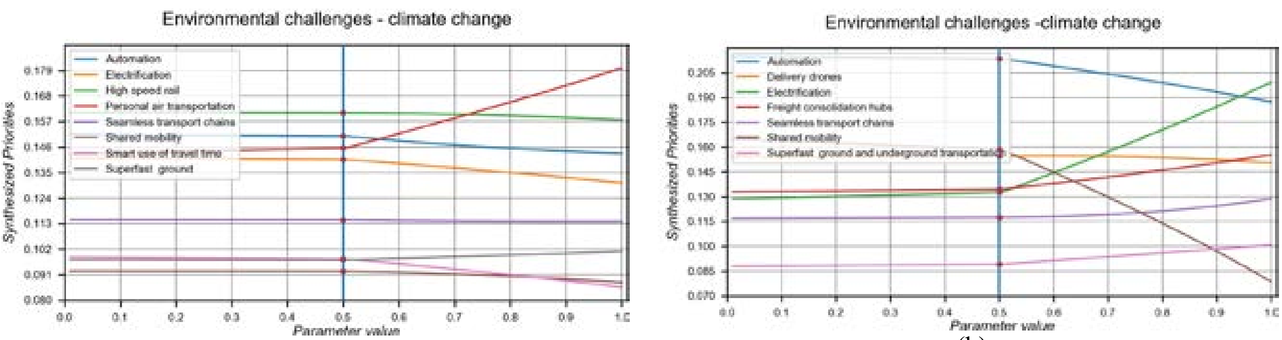
4. Sensitivity Analysis

Chapter 3 specifies the priorities of transport concepts of the future while the impacts of megatrends are validated. But how much stable is the result of megatrend validation? How sensitive are the transport concepts of the future priorities to the changes of the megatrends importance? The answer to these questions can be obtain by using the sensitivity analysis.

The sensitivity analysis is conducted to understand how the priorities of the TCF are robust and responding to the changes in megatrends, political imperatives and technological advances influence on the whole of the ANP network. The row sensitivity method has been used because this method enabled us to preserve the ANP structure (Adams, 2011). This implies following the change of the TCFs priorities in relation to the change in the importance of only one megatrend - the direct impact of megatrend (line charts). The moments of the TCF ranking changes when the megatrends importance is changed are shown as dots in cross-check of two lines. The change of the priority of all megatrends is shown on the spider graphs that define the stability of the first-ranked TCF solution. The space of the stability of the results is marked with transparent light green, and it indicates the stability of the best ranking TCF.

The example of the sensitivity of TCFs with respect to Environmental Challenges – climate change for the passenger and freight transportation is given in Figure 3(a) and 3(b). Normalized TCFs scores are displayed with the solid lines as a function of the parameter value. As can be seen in Figure 3(a) changes of megatrend Environmental changes - climate change importance is most reflected in the change of the Personal air transportation concept and Smart use of travel time. In the first case, we can say that the impact of the megatrend is direct and positive so that it quickly leads to a change in the Personal air transportation rank and it becomes the best ranked TCFP. In the case of TCFP Smart use of travel time, the impact of the megatrend is such that it loses its position and falls to the last position from the sixth place.

As can be noted from Figure 3(b), the initial rank of TCFFs obtained after the evaluation of all respondents is changed with the increase of the Environmental challenges – climate change megatrend impact. There are eight changes in the ranking of TCFFs. The rise of megatrend impact has mostly affected TCFFs Shared mobility and Electrification. Share mobility in the final ranking moves from the third place to the last position and Electrification from the fifth place moves to the first position. Therefore, it can be expected that with the increase of the Environmental challenges - climate change megatrend impact Electrification, a concept that characterizes the use of clean energy sources and environmental protection, will continue to penetrate each market at a different pace.

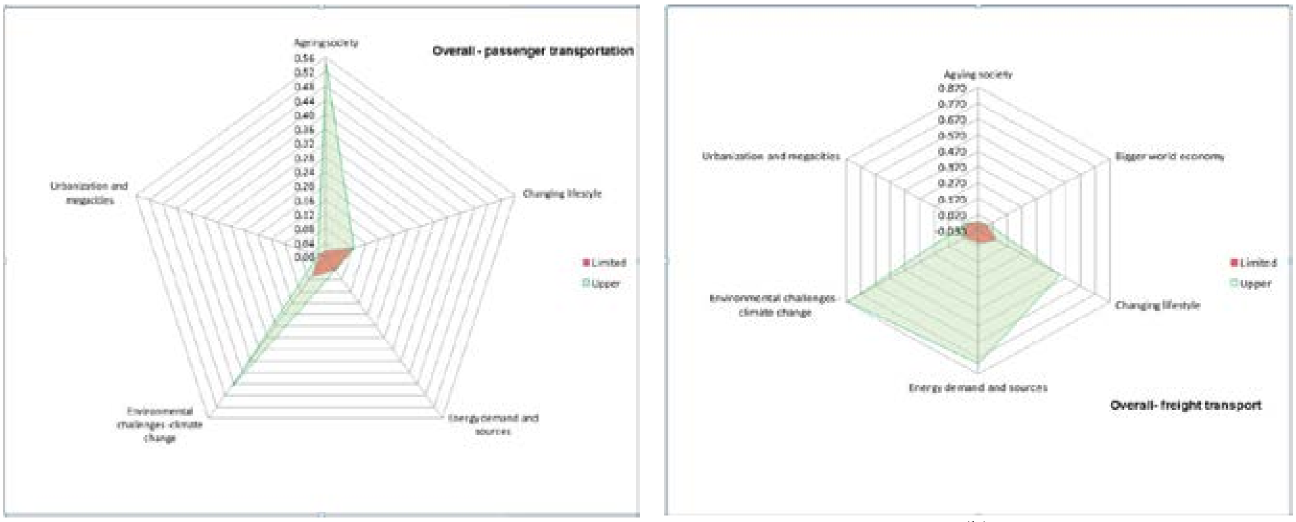


(a) (b)

Fig. 3.
Modifications of TCFPs scores with respect to Environmental challenges – climate change megatrend priority changing for passenger transport (a) and freight transport (b)

The impact of all megatrends is illustrated on the spider charts that define the stability of the best ranked TCF score. Spider chart is used for seeing how much the change of importance of a given megatrend causes a change in the first ranking TCF. Each megatrend is provided with the axis, and the same scale is between all axes. Each megatrend limited

and upper value is shown along with its own axis. Megatrends limited value are connected together and form one polygon (red color), and connected upper values form another polygon (light green color).
In the Figure 4(a) red color polygon illustrates the impacts of the megatrends on the TCFPs ranking. The light green color polygon represents the upper values of the megatrends at the moment when the best-ranking TCFP change its rank. For the outcomes for the passenger transport, megatrends Ageing society and Environmental challenges-climate change impact on the ranking of the High-speed train. The small change of the priority value for the Changing lifestyle, Energy demand and sources and Urbanization and megacities do not lead to the changes of the best-ranking TCFP. The space outside the cross-section of the two polygons represents the instability of the outcomes.
In the Figure 4(b) is presented the impact of the megatrends on the TCFFs ranking. Outcomes for the freight transport, megatrends priorities for Changing lifestyle, Energy demands and sources and Environmental challenges-climate change impact on the ranking of the TCFF Automation. In the long-term TCFF Automation will have a revolutionary impact on travel behavior that is confirmed with a high ranking influence on Changing lifestyle and the robustness of the solution. The small change of the priority value for the Ageing society, Bigger world economy, and Urbanization and megacities do not lead to the changes of the best-ranking TCFF.



(a) (b)

Fig. 4.
The impact of the megatrends on the best-ranking TCF for (a) passenger transport – (High-speed train) and (b) freight transport - (Automation)

5. Conclusion

The outcomes from the ANP network for passenger transport shows that the highest priority values of TCFPs has High-speed rail. Looking ahead, the second, third and fourth TCFP is very close to the first one, and these are Personal air transportation, Automation, and Electrification. According to the differences between the priorities value of the first four TCFPs all of them can be taken into consideration in future research.
It can be noticed that megatrends Changing lifestyle and Environmental challenges - climate change take an important first or second place so that they can be considered as the leading megatrends that influence the determination for future research needs.
Focusing on the priorities of TCFFs it shows that the Automation is dominant. TCFFs Delivery drones and Shared mobility ranked second and third, are with a significant difference in priority value compared to Automation. Significantly stands out the influence of the megatrends Changing lifestyle. The following megatrends have a slightly less impact: Urbanization and megacities, Energy demand and sources, Bigger world economy and finally Ageing society.
Looking at the similarities and differences between the results obtained for passenger and freight transport, it can be said that TCF Automation is the first ranked. This raises the question of what are the reasons for such a perception of the experts? The answer might lie with the fact that key megatrends for freight transport Changing lifestyle and Environmental changes – climate change and Urbanization and megacities are closely linked to Digitalization strategy/regulations /markets as key political imperatives and Automation freight transport as the first technological advances. All of these elements are in close interconnection so that it is not possible to precisely determine what the cause is and what is the consequence and to what extent this relationship is. Actually relations Automation-Changing lifestyle-Urbanization-Digitalization-Automation freight transport represent one loop or circle in which one another stimulates, causes, and in multiplication cooperate.
The outcomes from the sensitivity analysis illustrated that the most influential megatrends for passenger transport and for freight transport as well are: Energy demand and sources and Urbanization and megacities. Bearing in mind stability

of the ANP model outcomes Energy demand and sources megatrend is the megatrend with the biggest influence on best ranking TCFs priorities.

Acknowledgment

The results incorporated in this paper received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 769638, project title: INtentify future Transport rEsearch NeeDs (INTEND).

A GAP ANALYSIS FOR TRANSPORT CONCEPTS OF THE FUTURE

Vladislav Maraš [1], Danijela Pjevčević[2], Aleksandar Radonjić[3]
[1,2,3] University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, Belgrade, Serbia

Abstract: The main objective of this paper is analysis and assessment of the realization of the defined transport concepts of the future. The advantages of each of the defined transport concepts of the future and the obstacles that could appear on the path of their realization have been analyzed. The idea is to define priority areas for future transport research programs by defining a list of priority gaps.

Keywords: transport concepts of the future, passenger transport, freight transport, gap analysis.

1. Introduction

Transport concept has been defined as a concept or idea that presents how mobility takes place between two places, referring to movement of passengers or freight (INTEND, 2018). It may describe the vehicle and the way that transportation or mobility takes place.
Eight top-cited concepts for passenger transport were identified in INTEND, 2018. The transport concepts presented here, are ranked according to their frequency of occurrence in the reviewed literature:

- **automation – passenger transport** (driverless vehicles, including autonomous cars, aircrafts, trains, vessels for passenger transportation).
- **shared mobility, on-demand mobility, MaaS** (shared mobility schemes, such as car-, bike- and ride-sharing, ride hailing, car-pooling, etc.; on demand mobility, demand-responsive mobility; MaaS – a single-digital service offering that integrates various public and private forms of transport and provides end-to-end journey planning, booking and payment options).
- **electrification – passenger transport** (electric-powered vehicles, including electric cars, trains, aircrafts and vessels/ferries for passenger transportation).
- **seamless transport chains – multimodality, intermodality** (seamless transport chains for passenger transport; seamless national and international travel for passengers; seamless passenger travel as a result of MaaS).
- **personal air transportation – "flying cars", "flying taxies"** (urban air mobility; passenger drones for urban passenger transport).
- **smart use of travel time** (time made available because of vehicles automation; travel time as a usable timeslot for leisure, socializing or work-related activities).
- **high-speed rail** (high-speed trains for passenger transport; high-speed rail networks as an attractive alternative to aviation).
- **superfast ground and underground transportation** (hyperloops for passenger transport; hyperloop for faster and more sustainable surface transportation).

In addition, seven transport concepts of the future related to freight transportation, presented below, are also ranked according to their frequency of occurrence in the reviewed literature:

- **shared mobility, on-demand mobility, MaaS, FaaS, LaaS** (mobility as a service – MaaS as last mile for freight transport; "freight as a service" – FaaS for more efficient goods shipping and delivery possibilities; "logistics as a service" – LaaS – to give consumers more control and flexibility over their home deliveries; LaaS to enable individuals to choose their own logistics service provider and bundle deliveries as they wish).
- **seamless transport chains – multimodality, intermodality** (seamless transport chains for freight transport; seamless logistics – smooth combination of different modes and minimization of delays / interruptions in the logistic chain; seamless multimodal freight transport services).
- **automation – freight transport** (driverless vehicles, including autonomous trucks, trains and vessels for freight transportation).
- **electrification – freight transport** (electrified vehicles, including electric trucks, aircrafts and vessels for freight transportation).
- **delivery drones** (small unmanned air vehicles supporting urban deliveries; delivery drones as an indivisible part of the supply chain; delivery drones to cater for hard-to-reach areas).
- **superfast ground and underground transportation** (cargo tubes; underground freight transportation pipelines in dense urban centres, as an alternative to the conventional transport systems; underground freight pipelines for moving goods within and between urban areas).
- **freight consolidation hubs, freight distribution centres** (multimodal settlements that provide access to different modes of transport for transport-oriented companies, logistic service providers and production enterprises; inter-modal infrastructure facilities provision; optimization of deliveries, efficiency increase and traffic/emissions reduction in city centres).

2. Methodology

This chapter describes the approach for analysis and identification of existing gaps. The gaps, in this case, can be considered as the missing links between the strategic breakthroughs of transport concepts of the future and the major obstacles to their achievement.
Therefore, for the proposed key transport concepts of the future for freight and passenger transport, it is necessary to determine a list of breakthroughs and obstacles to their achievements. In this process, we consulted and reviewed previous transport related projects (both in passenger and freight transport), academic literature, reports from business sector and consultancy firms, relevant websites, synopsis tools and databases.
By crossing the breakthroughs and obstacles of the transport concepts of the future, we have identified existing gaps and consequently a proposal for their possible overcoming has been made (Figure 1).

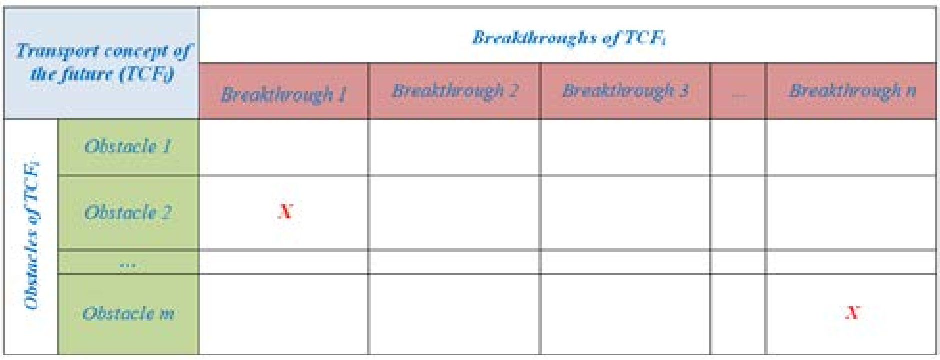

Fig. 1.
Example of gap analysis for TCF$_i$

Based on the defined list of gaps, we will analyze whether these gaps exist in the defined sketch of the transport system of the future.

3. Gap Analysis Results

In this part of the paper, an individual analysis of the proposed transport concepts of the future has been carried out and for each of them the breakthroughs and obstacles are presented. Their crossings enabled us to identify the gaps.

3.1. Transport Concept of the Future: Automation – Passenger and Freight Transport (Autonomous Cars, Trucks, Aircraft, Trains, Vessels)

INTEND, 2018 defines transport concept "Automation – Passenger and Freight Transport (autonomous cars, trucks, aircrafts, trains, and vessels)" as follows:
"*Autonomous – driverless vehicles operating with no need for any human intervention; autonomous cars; autonomous trucks, platooning technology for heavy duty vehicles, autonomous networks of long-haul trucks; autonomous passenger aircrafts; automated trains for passenger and freight transport; autonomous ferries and vessels for passenger and freight transport, automation – platooning of vessels/ferries*".
Further, it is possible to identify some specific characteristics of the breakthroughs and obstacles collected for this TC (Automation – Passenger and Freight Transport) in various transport modes. These are:

- Road transport – 11 breakthroughs and 17 obstacles (Table 1);
- Air transport – 3 breakthroughs and 8 obstacles (Table 2);
- Rail transport – 3 breakthroughs and 7 obstacles (Table 3);
- Water transport – 2 breakthroughs and 5 obstacles (Table 4).

Table 1
*Breakthroughs and obstacles of TC Automation – Passenger and Freight Transport - **Road transport***

TC Automation – Passenger and Freight Transport - Road transport	**Breakthroughs**										
	Increased safety	Better use of travel time	More efficient	Energy savings	Decreases in polluting emissions	Provision of mobility services to people currently unable to drive	Reduction in the need for parking space	The high cost of AVs may accelerate the move to shared mobility	Roadway infrastructure could be managed dynamically	Reduce the need for pedestrian areas	Predictable travel times

Obstacles	Increased congestion and pollution					**X**		**X**				
	A shift away - from public transit											
	Longer trips (especially commutes)											
	Repositioning				**X**							
	Security	**X**					**X**					
	Traffic management											
	City Infrastructure									**X**		
	Revenue								**X**			
	Liability insurance											
	Police and emergency response											
	Social justice and equity		**X**									
	Creating (and maintaining) maps for self-driving cars is difficult work											
	Driving requires many complex social interactions — which are still tough for robots											
	Bad weather makes everything trickier											
	Regulations											
	Cyber security	**X**

	Cyber Security		X

3.2. Transport Concept of the Future: Shared Mobility, On-demand Mobility, MaaS, TaaS, FaaS, LaaS

INTEND, 2018 defines transport concept "Shared mobility, on-demand mobility, MaaS, TaaS, FaaS, LaaS" as follows: *"Shared ownership models, on-demand mobility; proliferation of car/ride/ fleet-sharing and ride-hailing; novel sharing concepts; Mobility as a Service – MaaS, Freight as a Service – FaaS, Logistics as a Service – LaaS".*
It is possible to identify some specific characteristics of the breakthroughs and obstacles collected for this *TC Shared mobility, on-demand mobility, MaaS* which allow the identification of 10 breakthrough and 5 obstacles (Table 5).

Table 5
Breakthroughs and obstacles of TC Shared mobility, on-demand mobility, MaaS

TC Shared mobility, on-demand mobility, MaaS		**Breakthroughs**									
		Integration of transport	Tariff option	One platform	Multiple actors	Use of technologies	Demand orientation	Registration requirement	Personalisation	Customisation	Discussion of MaaS's Roles in Future Mobility
Obstacles	Travel demand modelling for MaaS						X				
	Supply-Side Modelling										
	The benefits may be limited										
	MaaS can still face strong competition from existing travel applications	X									
	Policy Framework for Implementation of MaaS				X	X					

3.3. Transport Concept of the Future: Electrification – Passenger and Freight Transport (Electric Cars, Trucks, Aircrafts, Trains, Vessels)

Similarly, it is possible to identify some specific characteristics of the breakthroughs and obstacles collected from the literature for this *TC Electrification – Passenger and Freight Transport* for various transport modes, i.e.:

- *Road transport* – 3 breakthrough and 7 obstacles (Table 6);
- *Waterborne transport* – 6 breakthrough and 3 obstacles (Table 7);
- *Air transport* – 1 breakthrough and 3 obstacles (Table 8).

Table 6
Breakthroughs and obstacles of TC Electrification – Passenger and Freight Transport – ***Road transport***

TC Electrification – Passenger and Freight Transport - Road transport		**Breakthroughs**		
		Electricity Energy (efficient and utilize)	Improving local and regional air quality	Benefit for shareholders and owners of EVs
bs ta cle	Electric parking spaces	X		
	High costs			

	Uncomfortable and slow charging	X		
	Limited range	X		
	Availability			
	Accessibility and awareness		X	
	Space required for storing electricity (battery) in the vehicle	X		

Table 7
Breakthroughs and obstacles of TC Electrification – Passenger and Freight Transport – ***Waterborne transport***

TC Electrification – Passenger and Freight Transport - Waterborne transport		**Breakthroughs**					
		Flexibility of ship design	Flexibility of the ship's operation	Silencing the noise on the boat	Improved efficiency of fuel consumption	Effectively operated with On/Off technology	Powering the ship
Obstacles	Power solutions						X
	Higher initial cost				X		
	Adequate charging infrastructure						

Table 8
Breakthroughs and obstacles of TC Electrification – Passenger and Freight Transport – ***Air transport***

TC Electrification – Passenger and Freight Transport - Air transport		**Breakthroughs**
		Reduction in CO_2 emissions
Obstacles	Emerging challenges for the development of leading-edge need to be aligned with key principles	
	Management and standardization competencies	X
	Training workers	

3.4. Transport Concept of the Future: Seamless Transport Chains

Transport concept "Seamless transport chains" was described in INTEND, 2018 as follows:
"Seamless transport chains for both passenger and freight transport; seamless national and international travel for passengers; seamless logistics; seamless multimodal freight transport services; integration of all transport modes – multimodality, intermodality; seamless transport chains as a result of MaaS."
Genuine seamlessness is vital for the smooth transport of people, raw materials and products and thus is **central to economic growth** (ITR, International Transport Forum). **Seamless services save time, money and the environment.**
Some of the reviewed literature sources proposed seamless transport as a key future transport concept, in the scope of MaaS. That is why there is overlapping of the advantages and obstacles on the way of the rationalization of these two future transport concepts.
Table 9 identifies some specific characteristics of the breakthroughs and obstacles for *TC Seamless transport chains* collected from the literature. We identified in total three breakthroughs and eight obstacles.

Table 9
Breakthroughs and obstacles of TC Seamless transport chains

TC Seamless transport chains		**Breakthroughs**		
		Energy efficiency	Reduced emissions	Integration
Obstacles	Coordination and collaboration			X
	Adequate structure and the coherence system			
	Development of transhipment technology			
	Efficient management systems	X		
	Fast and low cost handling of loads			
	Work in the cross-border network			

	Electronics and business models			
	Regulations			X

3.5. Transport Concept of the Future: Personal Air Transportation – “Flying Cars”, “Flying Taxis”

INTEND, 2018 describes transport concept "Personal air transportation – flying cars, flying taxis" as follows: *"Urban air mobility; small personal aerial vehicles manually piloted, remotely piloted or fully autonomous; “Passenger Drones”, “Flying Cars”, “Flying Taxies”."*
Therefore, based on the literature, it is possible to identify some specific characteristics of the breakthroughs and obstacles related to this *TC Personal air transportation – “flying cars”, “flying taxis”*. In total, we have identified 4 breakthroughs and 6 obstacles (Table 10).

Table 10
Breakthroughs and obstacles of TC Personal air transportation – “flying cars”, “flying taxis”

TC Personal air transportation – “flying cars”, “flying taxis”		**Breakthroughs**			
		Avoid congestion on road	Enhance personal transportation, revolutionize the transportation industry, and improve the standard of living	Infrastructure	Reduced emissions, fuel use, and capital cost
Obstacles	Air traffic control and infrastructure			X	
	Cost and accessibility	X			X
	Safety		X		
	Charging				
	Regulation			X	
	Affects other sectors		X		

3.6. Transport Concept of the Future: Delivery Drones

Transport concept "Delivery Drones" can be described as follows (INTEND, 2018):
"Urban airspace utilization for goods deliveries; delivery drones as a part of the supply chain."
In addition, literature review allowed for the identification of 7 breakthrough and 47 obstacles related to this TC (Table 11).

Table 11
Breakthroughs and obstacles of TC Delivery Drones

TC Delivery Drones		**Breakthroughs**						
		Cost effective	Deliver Products	Improves Time Management	Conserves Energy	Saves Time	Promote Safety	Accuracy
Obstacles	Regulation			X

3.7. Transport Concept of the Future: Smart Use of Travel Time

INTEND, 2018 defines the transport concept "Smart use of travel time" as follow:
"Use of travel time made available because of vehicle automation; travel time as a usable timeslot for a wide range of activities."
The same report (INTEND, 2018) recognizes that the smart use of travel time, as a transport concept of the future, is a direct consequence of the autonomous driving.
Accordingly, many of the obstacles that are present in autonomous driving and have been processed in Chapter 2.1.1 are also relevant for the transport concept “Smart use of travel time” and will not be considered again.

3.8. Transport Concept of the Future: High-Speed Rail

Transport concept "High-speed rail" was described in INTEND, 2018 as follows:
"High-speed train technologies; high-speed rail for passenger transport."
Based on the literature review, we were able to identify 3 breakthrough and 4 group of obstacles which are mostly relevant for this TC (Table 12).

Table 12
Breakthroughs and obstacles of TC High-speed rail

TC High-speed rail		**Breakthroughs**		
		Attractive alternative to aviation	High-speed rail as a cheaper, greener and more sustainable transport alternative	Need for a complete European high-speed rail network
Obstacles	Technical obstacles			
	Changes in environmental, human health, resource, and climate change impacts		X	
	Problems of the impact of rail development			
	Costs and challenges facing the HSR		X	

3.9. Transport Concept of the Future: Hyperloops

Transport concept "Hyperloops" was described in INTEND, 2018 as follow:

"*High-speed train technologies; high-speed rail for passenger transport*."
We have also identified some specific characteristics of the breakthroughs and obstacles collected from the literature and related to this *TC Hyperloops* which allow for the identification of 5 breakthroughs and 10 obstacles (Table 13).

Table 13
Breakthroughs and obstacles of TC Hyperloops

TC Hyperloops		Breakthroughs				
		Very fast	Power	Cheaper for travelers	Weather	The Hyperloop will arrive more frequently
Obstacles	Construction cost and Environmental impact			X		
	Construction material					
	Pressure					
	Spontaneous Decompression					
	Deadly Collisions	X				
	Acceleration of the capsule					
	The multi-ton capsules intended to carry passengers also pose as liabilities themselves					
	Too much air creates significant problems					
	Safety standards and security			X		
	New management challenges					X

3.10. Transport Concept of the Future: Freight Consolidation Hubs, Freight Distribution Centres

INTEND, 2018 describes transport concept "Freight consolidation hubs, Freight Distribution Centres" as follows: *"(Peri)-urban freight consolidation hubs; freight hubs located close to urban agglomerations, for goods consolidation between long distance hauls and short-distance inner-city transport; Freight distribution centres (freight villages); multimodal settlements that provide access to different modes of transport as well as several inter-modal infrastructure facilities, for transport-oriented companies, logistics service providers, etc."*
Literature review has allowed for identification of 8 breakthroughs and 9 obstacles (Table 14) relevant for this TC (*TC Freight consolidation hubs, Freight Distribution Centres*).

Table 14
Breakthroughs and obstacles of TC Freight consolidation hubs, Freight Distribution Centres

TC Freight consolidation hubs, Freight Distribution Centres		Breakthroughs							
		Environmental and social benefits resulting from more efficient and less intrusive transport operations within urban areas	Possible facilitate a switch from push to pull logistics through better control and visibility of the supply chain	Better inventory control, product availability and customer service	Potential to link in with wider policy and regulatory initiatives	Theoretical cost benefits from contracting out "last mile"	Public relations benefits for participants	Potential to allow better use of resources at delivery locations	Specific transport advantages opportunity for carrying out value-added activities
ta	Potentially high set up costs (and sometimes high operating costs) (Browne, et al., 2005)					X			

	Logistical zones in the area of the port have some disadvantages, especially because they involve higher land costs with potentially more restrictive labor regulations if they are under the jurisdiction of port workers. (Rodrigue, 2017)								
	Much urban freight is already consolidated at the intra-company level or by parcels carriers, so limited benefits (or even negative consequences) for trying to channel these flows through a consolidation centre. The potential scope for UCCs may therefore be limited. (Browne, et al., 2005)								
	Difficult for a single centre to be able to handle the wide range of goods moving in and out of an urban area, for example due to different handling and storage requirements. (Browne, et al., 2005)								
	Most studies report an increase in delivery costs due to an additional stage in supply chain which imposes a cost (and often a time) penalty, though this clearly depends on how well the centre is integrated into the supply chain and the extent to which all costs and benefits are considered. (Browne, et al., 2005)		X						
	Single consolidation centre for an urban area is unlikely to be attractive for many suppliers' flows due to the degree of diversion required from normal route (and may therefore negate transport savings for onward distribution). (Browne, et al., 2005)								
	Lack of enforcement of regulations for vehicles not included in the consolidation scheme. (Browne, et al., 2005)								
	Organizational and contractual problems often limit effectiveness. (Browne, et al., 2005)	X							
	Potential to create monopolistic situations, thus eliminating competition and perhaps leading to legal issues. (Browne, et al., 2005)								
	Loss of the direct interface between suppliers and customers. (Browne, et al., 2005)								

3.11. Transport Concept of the Future: Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines

INTEND, 2018 describes transport concept "Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines" as follows:
"Hyperloops, Cargo Tubes, Underground Freight Pipelines (e.g. "CargoCaps")"
For this TCF, we identified 5 breakthroughs and 6 obstacles from the relevant literature (Table 15).

Table 15
Breakthroughs and obstacles of TC Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines

TC Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines		Breakthroughs				
		Safety and security	Reliability	Environment	Delivery times	Transport Costs
Obstacles	Technology acceptance	X				
	Intermodal transfer with existing modes		X			
	Support for adoption					
	Costs and funding					X
	Design and construction					
	Competition					

4. Results

After overviewing all TCF breakthroughs and obstacles that are present on the realization path for each of them, Table 16 gives a summary of all identified gaps.

Table 16
List of TCF gaps

TCF		Breakthroughs	Gaps
TC1: Automation – Passenger and Freight Transport	**Road transport**	Increased safety; Provision of mobility services to people currently unable to drive	**1.Security, Cyber security**
		Better use of travel time	**2.Social justice and equity**
		Energy savings	**3.Repositioning**
		Decreases in polluting emissions; Reduction in the need for parking space	**4.Increased congestion and pollution**
		The high cost of AVs may accelerate the move to shared mobility	**5.Revenue for city**
		Roadway infrastructure could be managed dynamically	**6.City Infrastructure**
	Air transport	Energy efficiency	**7.Safety**
			8.Technology maturity
		Low engine power	**9.Infrastructure**
	Rail transport	Capacity	**10.Infrastructure (in metro)**
		Costs and energy efficiency	**11.Functional safety**
			12.IT security
		Fully automated rail freight system	**13.System integration**
	Waterborne sector	Advanced in modern ships	**14.Changes in the ports**
		Safety and energy efficiency	**15.Regulatory Framework**
			16.Insurance
			17.Cyber Security
TC2: Shared mobility, on-demand mobility, MaaS, TaaS, FaaS, LaaS	**MaaS**	Integration of transport	**18.MaaS can still face strong competition from existing travel applications**
		Multiple actors	**19.Policy Framework for Implementation of MaaS**
		Use of technologies	
		Demand orientation	**20.Travel demand modelling for MaaS**
TC3: Electrification – Passenger and Freight Transport	**Road transport**	Electricity Energy (efficient and utilize)	**21.Electric parking spaces**
			22.Uncomfortable and slow charging
			23.Limited range
			24.Space required for storing electricity (battery) in the vehicle
		Improving local and regional air quality	**25.Accessibility and awareness**
	Waterborne sector	Improved efficiency of fuel consumption	**26.Higher initial cost**
		Powering the ship	**27.Power solutions**
	Air transport	Reduction in CO_2 emissions	**28.Management and standardization competencies**
TC4: Seamless transport chains		Energy efficiency	**29.Efficient management systems**
		Integration	**30.Coordination and collaboration**
			31.Regulations
TC5: Personal air transportation - "flying cars", "flying taxis"		Avoid congestion on road; Reduced emissions, fuel use, and capital cost	**32.Cost and accessibility**
		Enhance personal transportation, revolutionize the transportation industry, and improve the standard of living	**33.Safety**
			34.Affects other sectors
		Infrastructure	**35.Air traffic control and infrastructure**
			36.Regulation
TC 6: Delivery Drones		Cost effective	**37.Requires investment**
			38.Drone insurance

		39.Drone financing
		40.Flying drone bill of rights
	Deliver Products	**41.Order staging**
		42.Designated delivery spots
		43.Classification system for drone and cargo
	Improves Time Management	**44.Regulation**
		45.Licensing (Vehicle, Pilot, Operator)
		46.Education for the drone police, for drone lobbyists, for drone maintenance and repair, Education & certification for drone pilots
	Saves Time	**47.Conditional awareness**
	Promote Safety	**48.Safety**
		49.Shipping big-ticket items
		50.Override kill switch
	Accuracy	**51.Docking systems**
TC 8: High-speed rail	High-speed rail as a cheaper, greener and more sustainable transport alternative	**52.Changes in environmental, human health, resource, and climate change impacts**
		53.Costs and challenges facing the HSR
TC9: Hyperloops	Very fast	**54.Deadly Collisions**
	Cheaper for travelers	**55.Construction cost and Environmental impact**
		56.An easy terrorist target
	The Hyperloop will arrive more frequently	**57.New management challenges**
TC 10: Freight consolidation hubs, Freight Distribution Centres	Environmental and social benefits	**58.Organizational and contractual problems often limit effectiveness.**
	Possible facilitate a switch from push to pull logistics through better control and visibility of the supply chain”	**59.Increase in delivery costs**
	Theoretical cost benefits from contracting out “last mile	**60.Potentially high set up costs (and sometimes high operating costs)**
TC 11: Superfast Ground and Underground Transportation, Cargo Tubes, Underground Freight Pipelines	Safety and security	**61.Technology acceptance**
	Reliability	**62.Intermodal transfer with existing modes**
	Transport Costs	**63.Costs and funding**

As we can see from the Table 16, we have identified 63 gaps in total. Clarification of identified gaps, i.e. an explanation of which obstacles should be overcome so as the TCF would function and come to life, is given in Table 17.

Table 17
Description of Gaps

Gaps
1.Security, Cyber security Automated vehicles could be used for terrorist attacks (as ar bomb for instance) without any physical risk and with much lower risks of detection for the terrorist. Moreover, automated vehicles could be hacked for malicious purposes. (Franckx, 2015) "Another question is cyber security", "How do you ensure that these cars cannot be hacked? How vehicles become smarter and connected, there are more ways to get in and disturb what they do." This should not be impossible to fix. Software companies have long been facing this problem. (Plumer, 2016)
2.Social justice and equity There is a risk that AV would benefit more from the rich and create a higher burden for low-income people. These without AV can be in a disadvantageous position when it comes to employment, because they can work with AV and respond to e-mail while travelling. (GovTech, 2017)
3.Repositioning After having dropped their passenger, the AVs will now have to drive to places where parking is available (or cheaper), or to catch other users (which could be other family members, or, in the case of shared cars, third parties); this “repositioning” could have an important impact on traffic flows. (Franckx, 2015)
4.Increased congestion and pollution Increased congestion and pollution caused by travel by those currently unable to drive, such as young people without

Gaps
driving license, the physically impaired, and elderly people. (Franckx, 2015) It is not clear to what extent autonomous cars will really lead to shorter headways -One should not compare the theoretical safety distance between AVs with the theoretical safety distance between vehicles driven by humans as a lot of people drive closer to the preceding car than is justified on safety grounds; (Franckx, 2015) Le Vine and at. 2016, examined the impact of the dynamics of driving autonomous vehicles on congestion in traffic. Autonomous vehicles which offer a comfortable ride similar to slowing down and acceleration on the rail, create more traffic congestion than a man behind the wheel. When driverless cars accelerated and decelerated in the style of light rail, the congestion deteriorated from 4 percent to 50 percent and the number of cars travelling through the intersection also fell between 4 percent and 21 percent. Going for high speed rail style of smoothness, those numbers got even worse: Delays increased from 36 percent to nearly 2,000 percent and intersection capacity fell between 18 percent and 53 percent. Only the vehicles with drivers and autonomous vehicles are included in simulation in study. There were no trucks, buses, or pedestrians
5.Revenue for city AVs will not go to red light, they will not accelerate to the highway over the permitted border or park outside the permitted parking space. This, however, will affect the city budget. In some cities, traffic fines make a significant percentage of the city's budget. Cities will need to generate new revenue streams to counter the loss of funds. (GovTech, 2017)
6.City Infrastructure Often, AVs require a clear striming stripe, storage locations for data collected during guidance, and a robust network of climbing if they are working on electricity. (GovTech, 2017)
7.Safety Obstacles to the advancement of automation depend on basic safety concerns (a key problem due to potential loss of life and poor publicity that may be the result of a collision of aircraft). (Spinardi, 2015) For the adoption of passenger drones and flying cars (especially fully autonomous), operators of these vehicles should show a safety record covering both mechanical integrity and safe operations. As has been shown in autonomous cars, any accidents can have considerable attention and can slow down the adoption of such a concept. (Lineberger et al., 2018)
8.Technology maturity Although GPS technology exists and is used in autonomous cars, it should be improved to provide remote sensing and recognition needed to deal with the multi-way and fast convergence associated with the autonomous flight. These vehicles would require advanced technologies, such as artificial intelligence, to allow advanced detection and avoidance capabilities. Machine learning can be essential since operations move from piloted to autonomous: the vehicle should learn from pilots on the basis of over a thousand working hours to become completely autonomous over time. Energy management is crucial: to have enough energy to transport passengers or cargo, to maintain a safety margin and reload for the next flight. Although the technology of using batteries as a source rapidly improves, in order to increase the capacity of passengers and cargo and extend the range of passenger drones, it is necessary to further improve or to find alternatives. (Lineberger et al., 2018)
9.Infrastructure In terms of infrastructure, it is necessary to provide the appropriate landing and landing zone, as well as the charging stations for the battery. A broad network requires new infrastructure or the conversion of existing infrastructure (such as helipads, roofs of large public buildings and unused land). In order to provide a unified traffic management system, additional infrastructure along the predefined flight corridors should be installed to help rapidly communicate data and geolocation. All these changes in infrastructure would require cooperation with commercial actors and local urban planning bodies. (Lineberger et al., 2018)
10.Infrastructure (in metro) Modification or replacement of vehicle fleet and signaling system and additional complexity can increase costs in comparison with other signaling and control systems. Closing an existing system over a longer conversion period is likely to be difficult and costly, as existing metro lines often represent vital links in the urban transport network. In order to ensure high levels of security, a greater degree of physical segregation from the environment will be required than for trains in which a driver can react to extraordinary or unexpected events such as collapse, burning trees or damage to the infrastructure. This is not so significant for underground lines as it is important when converting a surface infrastructure that was not originally designed for such a high degree of isolation. A very high percentage of runs on which trains are currently running without a driver are underground or raised. By contrast, most of the metro is at the ground level, and it is likely that the peripheral line should be upgraded, as the crossing is a daily problem on the metro paths. It is necessary to improve the system of communication and tracking for passengers throughout the system in order to provide functions that would otherwise be performed by a staff member. This also applies to remote monitoring and correction (where possible) of equipment faults by the remote control center. The equipment requires a high degree of reliability and availability to ensure the safety of passengers. Such systems would represent **additional capital and maintenance costs**. (Powell, 2016)

Gaps
11.Functional safety Higher system complexity increases potential error rates and demands new functional safety approaches. (Bosch, 2017)
12.IT security More digitised and interconnected systems are exposed to numerous hazards and vulnerabilities. (Bosch, 2017)
13.System integration Smart systems need to communicate across rail services, transport modes and infrastructure. (Bosch, 2017)
14.Changes in the ports Increased ships' automation will require some changes in the ports, e.g. for maintenance of ships, as well as for increased automation in both approaches and landing. (EU, 2018)
15.Regulatory Framework So far, the legislation governing autonomous ships is totally unclear. The main concern concerns the provisions on the number of crew members and safety, as well as the construction standards. According to IMO International rules, all ships should be employed with a minimum number of crew members in order to be able to navigate. This rulebook should be amended to include vessels with special characteristics that will allow them to sail with less or no crew on board. The same situation is with regard to the safety of the ship, where minimum standards regarding the conditions of vessels and equipment should be applied. Building and maintenance standards that classification societies also provide should be materially supplemented, and these societies will require people with expertise in autonomous technologies. Safety in navigation and responsibility: it is probably the main concern of people who are still cautious about autonomous ships. A boat sailing in the open sea faces many risks associated with weather, other hurdles, or even risking being threatened by a third party (e.g. pirates). So, such an autonomous ship should be very intelligent to be able to control any potential risk. (Jokioinen, 2017)
16.Insurance Existing insurance (..., war risks, piracy risks, cargo insurance...) should be available. However, premiums may vary depending on the level of actual risks in the navigation of these vessels. (Jokioinen, 2017)
17.Cyber Security The new risk that can arise using remote navigation is a cyber security. In this way, a new type of piracy can be developed. Therefore, the systems should be developed in such a way that they will exclude unauthorized access but also give the shore master overriding authority over any unauthorized instruction. Furthermore, a new insurance cover may be required which will cover such type of risks. (Jokioinen, 2017)
18.MaaS can still face strong competition from existing travel applications Even if Maas would aim at a pan-European or global market, MaaS can still face strong competition from existing travel applications that have already offered global services. Maas service will have to work with existing providers. It remains unclear whether such providers are willing to integrate their platforms with MaaS. (Li & Voege, 2017)
19.Policy Framework for Implementation of MaaS Implementation of MaaS in the city can face financial challenges. Many cities subsidize public transport services. If Maas had a profit from his monthly subscriptions, this does not necessarily mean that the sale of tickets for public transport was realized. Government policy will have to define the MaaS business model in terms of public transport services. Many employers offer free passes for public transport for their employees when traveling by public transport. Often employees can get a tax reduction for travel expenses. If an employee chooses Maas instead of public transport, an employee may not be able to receive the same subsidy or tax cuts. So, only when local governments identified MaaS as a type of sustainable transport system with the same state subsidy policy or tax cuts, MaaS can be applied in a city where subsidies and taxes are offered for those traveling by public transport. (Li & Voege, 2017)
20.Travel demand modelling for MaaS Providing innovative services such as MaaS requires the continuation of ongoing modeling of demand based on activities, given the more dynamic context of modern lifestyles, social impact, ICT, responses to travel recommendation systems, attitudes and subjective considerations, and an increasing degree of uncertainty. It is necessary to think critically about how to expand existing models based on activities and models of elections in order to better capture the overall nature of travel behavior and the decision-making process related to MaaS. (Jittrapirom et al., 2017)
21.Electric parking spaces In large cities, the use of electric vehicles would result in the need for millions of electric parking spaces, which is a real challenge for implementation. Implementation of the EV fleet would also require changes in infrastructure, to allow significantly higher power supplies to chargers than is currently available. (García-Olivares et al., 2018)
22.Uncomfortable and slow charging Convenient and reliable re-charging has already been identified as one of the most important aspects to increase user acceptance of electric vehicles, but is most often neglected. One clear challenge is to provide appropriate charging capabilities to urban dwellers that often have to rely on overnight street parking and limited garage spaces in high-density populated city areas. Municipalities aim long-term to reduce the number of vehicles in cities and are reluctant to electrify a high number of parking spaces with bulky or unsightly charging stations that often do not fit easily in the townscape. These users will have to rely on quick-charge capabilities or charging during the day at work. Additionally, there is the possibility to

Gaps
promote this means of charging with incentives due to the potential usage in vehicle-to-grid applications. (ERTRAC, 2017)
23.Limited range Increasing range capability of electric vehicles remains a high priority, as previously mentioned, in order to increase user acceptance and win the broad mainstream market especially in comparison to conventional vehicles and current existing usage models of these vehicles. It is important to keep in mind, however, that increasing driving range supplied by the electro-chemical energy stored in the battery can only be achieved directly by increasing the size of the battery. Increasing the size of the battery increases the "installed" energy storage capability at an increased cost and increased size and weight. (ERTRAC, 2017)
24.Space required for storing electricity (battery) in the vehicle These problems can be solved by supplying electricity directly to the cables while the vehicle is active. Losses are limited to the conventional distribution of electricity and the power of electronics on the vehicle, and the exceptional efficiency of the electrical machine can be used at full scale. This advantage in the efficiency of the system, turns into significant benefits in operating costs. (eHighway, 2017)
25.Accessibility and awareness Other incentives such as access to the driver and parking access are high value, low-cost incentives for adoption. Local competencies must also play a role, ensuring that the local location and the license for a new EV service are quickly terminated. (SCE, 2017)
26.Higher initial cost The main disadvantages of all electric drives are the higher initial cost compared to the propulsion systems based on internal combustion engines, the increase in losses in the conversion of energy from fuel to propulsion, the greater the volume of the system due to the large number of component parts, and the issue of energy density in vessels with batteries. (EC, 2017)
27.Power solutions Due to the diversity of ships and sailing (some boats spend a week at sea and only a few days in the port, while other vessels are regular vessels), the power solutions for one type of ship are not suitable for another ship. (EC, 2017)
28.Management and standardization competencies At present, there is no established access to standards, however, in order to make the supply chain efficient, specific standards, including the definition of components (e.g. an electric motor considered to be a drive engine?). (EC, 2017)
29.Efficient management systems Introducing more efficient management systems and cross-port operations in consolidation/distribution nodes close to cities, preserving the added value of long journeys; (Perkins, 2012)
30.Coordination and collaboration Need for intermediation and coordination to overcome the power imbalance and to reduce searching and transaction costs, and to avoid moral hazard and opportunism. •Fair gain sharing: the presence of conflict in co-modal initiatives is also connected to the perception of the unfair share of gain. Fair gain sharing is a proxy for horizontal collaboration. •Information sharing and visibility: shippers and carriers do not collaborate horizontally because of competition law, fear of losing competitive advantage, and a lack of cross network visibility, among others. •Risk allocation: The existing literature allocates the risk related to co-modality (unused capacity, disruptions, delays, etc.) to the carrier which is usually in charge of the consolidation of different flows from its clients. (CO^3, 2012)
31.Regulations Too many regulations that hinder innovation. Different standards, regulations and procedures in member states prevent impeccable cross-border transport operations, as well as synchronic transport when logistics chains involve several countries. (Perkins, 2012)
32.Cost and accessibility Flying costs are more than driving, and the same goes for drones. It is estimated that average driving costs are 12 times higher for flying vehicles than those left on the ground. As far as personal planes are concerned, their price remains surprising. *(*Dewost, 2018); (Krauth, 2018)
33.Safety Private planes may be the closest device to mobility in air traffic, and are much more dangerous than cars. The biggest obstacle seriously delaying the great development of air traffic in urban areas is perhaps security, reflecting highly mediated discussions about autonomous accidents in the vehicle. The survey found that more than half of the Americans surveyed said that their main concern was the safety of autonomous flying cars. *(*Dewost, 2018); (Krauth, 2018)
34.Affects other sectors • Necessary co-operation of city-transport operators on demand with regulators to understand and respond to key regulatory issues (airspace management, fully autonomous adoption path, licensing and certification, and air traffic management). • Education of urban planners in terms of infrastructure conditions that are necessary in urban areas for operations with passenger drones to begin to involve them in urban planning processes in local communities.

Gaps
• Manufacturers should consider improving their concepts, working with regulators, and cooperating with urban transport operators on demand, in order to establish a market for their aircraft. In addition, manufacturers should begin to plan reduced production and subsequent aircraft support. • Drone technology providers should consider cooperation with drone manufacturers in order to fully understand their needs and integrate technological software, sensors, materials, engines and energy management into vehicles. Air Traffic Management Providers should consider working with their national airspace management regulators (such as the FAA in the United States) to participate in early pilot programs, formulating regulatory and standard standards, and adapting hardware and software to meet major quantity, low altitude and fully automated unique air traffic management systems in the future. (Lineberger et al., 2018)
35.Air traffic control and infrastructure There are numerous practical challenges in the direction of creating a regulatory management system: small drones are more susceptible to changes in time; the need for a dynamic mapping system that is updated in real time; connection for tracking constant tracking of drones in flight; and even interoperability, including devices that do not fly. Also, the lack of available free space and the difficulty of accessing up-and-down infrastructure (for landing and landing and flight safety) are significant obstacles, and the construction and design a vast network of vertiports is a major urban planning job in itself. *(*Dewost, 2018)
36.Regulation The existing rules, updated by the FAA in August 2016, insist that drones must be in the line of sight and must always be controlled live by the operator. Rules suffocates new innovations (at least in the U.S.). Other countries were welcomed by autonomous drones with open arms. For example, Delft agreed to implement the first fully autonomous network of unmanned aerial vehicles, complete with docking stations and drone rentals. New Zealand has been selected as the first commercial service for the delivery of drones in the world due to friendly regulations in the country. (Blair, 2017)
37.Requires investment The introduction of drones as part of the delivery process requires greater investment. The impression is that the investment will be more burdensome for smaller traders - or use third-party services that utilize drones. (Mehra, 2015)
38.Drone insurance Drones, drone cargo, and drone businesses will soon become the largest new market for insurance companies. (Frey, 2015)
39.Drone financing As the need for instrumentation and safety equipment mushrooms, delivery drones will become far more expensive. As a result, drone financing will become a hot new area of business in the near future. (Frey, 2015)
40.Flying drone bill of rights Do people have the right to “keep and bear drones?” (Frey, 2015)
41.Order staging In unmanned flights, the existing allocation process will have to be redesigned to support drones, and employees will have to train for these new processes. (Mehra, 2015)
42.Designated delivery spots Drones will need designated places for package delivery. (Frey, 2015) So flight is the easy part. Dropping off the package is the problem. Others address the issue by creating special landing zones. (Kobie),(Nentwich & Hórvath, 2018).
43.Classification system for drone and cargo Drones are being created in thousands of different shapes and sizes with thousands of different capabilities. A comprehensive classification system will be needed to properly manage and regulate this industry. Cargo classification systems applied to ground-based shipping will need to be revised for the more volatile conditions associated with remote controlled airborne vehicles. (Frey, 2015)
44.Regulation The second big challenge is regulation, and as ever the law trails innovation(Kobie)
45.Licensing (Vehicle, Pilot, Operator) Every drone that falls within certain classification guidelines will need to be licensed and insured. (Frey, 2015); (Nentwich & Hórvath, 2018). People who load and unload cargo onto flying drones will also need to be licensed. Those who fly drones will need to be tested and licensed in a less rigorous but similar way that airplane pilots are tested today. (Frey, 2015)
46.Education for the drone police, for drone lobbyists, for drone maintenance and repair, Education & certification for drone pilots People who service and fix drones will be in hot demand in the near future. Drones will become one of the most highly regulated industries of all times. It is not too soon to start educating the influencers. With all their different configurations, styles, and function, drone pilots will require far different training than airline pilots do. Currently there are very few simulation programs available for practice. Police will not only employ drones to assist in managing public safety, they will also use drones to monitor other drones. Drones are far more versatile and faster to deploy than virtually all other options officers have at their disposal. (Frey, 2015)

Gaps
47.Conditional awareness Drones will invariable fly into unusual situations, and whether it’s swarms of bees, bird attacks, lightening strikes, or signal jammers, they will need to alert operators of problems as soon as they arise. (Frey, 2015)
48.Safety Safety is very important the question of the fall of the drone from the sky, either by mechanical error or by the devious hacker. (Kobie) Health and safety - injuries because of collisions; contamination with dangerous loads. (Nentwich & Hórvath, 2018).
49.Shipping big-ticket items The drones will become the target of thieves as they fly several hundred meters from the ground. Retailers will have to consider this before using drones to send big-ticket items. (Mehra, 2015)
50.Override kill switch Wireless signals are far from perfect. If a signal is lost, hacked, or hijacked, the drone must either return home or be removed from danger. (Frey, 2015)
51.Docking systems People will eventually not want packages delivered onto their driveways. For example, any pizza left on a driveway becomes an open invitation for cats, dogs, and other stray animals. A better option would be to have some sort of docking system that would allow the drone to land and deliver the package into a secure area. (Frey, 2015)
52.Changes in environmental, human health, resource, and climate change impacts • spatial incompatibility between HSR and other long-distance modes that is often ignored, • an environmental review process that obviates modal alternatives, • siloed interest in particular environmental impacts, • dearth of data on future vehicle and energy sources, • poor understanding of secondary impacts, particularly in land use. (Chester and Ryerson, 2014)
53.Costs and challenges facing the HSR • Total per mile costs of providing rail service increase significantly with increases in travel speed, but ridership also increases with faster speeds, albeit less dramatically. Hence, there is a “sweet spot” where ridership and costs are optimized. This sweet spot also varies from corridor to corridor. • The feasibility and benefits of higher and high speed rail investments depend primarily on ridership. Therefore, it is important to focus initially on connecting major mega-regions with proven demand. • Certain metropolitan regions are more conducive to high speed rail by virtue of existing land use patterns and complementary public transportation service. It is important to provide rail service where people and economic activity are already concentrated, but it is also important to plan ahead for growing cities and regions. (Metcalf et al., 2010)
54.Deadly Collisions Capsule capable of sustaining force in the event of decompression should be extremely difficult given the nature of the design. The capsule must be strong enough to withstand atmospheric pressure inside the cabin, but it must remain light enough to not destroy or compromise the tube while traveling. Assuming it does not immediately destroy itself in pieces in the event of decompression, the capsules will accelerate the path until they collide with each other with deadly force. (Interesting Engineering, 2017)
55.Construction cost and Environmental impact Land acquisition and building/tunnelling rights. (Krauth, 2018)
56. Safety standards and security People are more concerned than ever about the threats of a terrorist attack. Designing hundreds of kilometers of tube transported by hundreds of people at the same time brings the real possibility of a terrorist attack. (Interesting Engineering, 2017), (Krauth, 2018)
57.New management challenges The dispatch system must meet the increased requirements for speed and reliability. It should provide simultaneous activation and execution of command sequences in the presence of a large number of different dispersed objects. (Dudnikov, 2017)
58.Organizational and contractual problems often limit effectiveness
59.Increase in delivery costs Most studies report an increase in delivery costs due to an additional stage in supply chain which imposes a cost (and often a time) penalty, though this clearly depends on how well the centre is integrated into the supply chain and the extent to which all costs and benefits are considered. (Browne, et al., 2005)
60.Potentially high set up costs (and sometimes high operating costs) Potentially high set up costs (and sometimes high operating costs) (Browne, et al., 2005) Logistical zones in the area of the port have some disadvantages, especially because they involve higher land costs with potentially more restrictive labor regulations if they are under the jurisdiction of port workers. (Rodrigue, 2017)
61.Technology acceptance One of the challenges is the acceptance of the technology as a viable alternative to conventional transport modes. it is

Gaps
not envisaged that this technology will completely replace other forms of transport but work in tandem with them to best optimize the transportation network. While this optimization is necessary, certain challenges exist with the use of this technology. (Egbunike and Potter, 2011)
62.Intermodal transfer with existing modes Pipelines will have to be connected to other types of transport and that the design boundary of such a system must include this interface. Efficiency and flawless transfer of goods in data exchange facilities, as well as an increase in the number of items for handling products, are of concern. (Egbunike and Potter, 2011) There are special disadvantages of the pneumatic tube mail system which are the inability to carry special delivery parcels due to the size of the carriers and because of that can carry only five pounds of mails in each container. (Shibani et al., 2016)
63.Costs and funding Related to the acceptance issue is financing. Investment costs can be considered factors that influence the underground infrastructure planning. When making the pipeline network a capsule, it is necessary that the network offers a long-term transport solution. However, obtaining a financial asset will only be possible if the technology proves itself. Operating costs will then depend on maintaining a constant flow of products through the pipeline. (Egbunike and Potter, 2011) The cargo transportation prices are rising each year. The high cost of creating and maintaining the vacuum tube and the tracking pipeline itself. (Shibani et al., 2016)

5. Conclusion

By overviewing the list of gaps, it is evident that some of the gaps are present in more TCFs. This is the case, for example, with Safety (TCF1, TCF5, TCF6,), Regulations (TCF1, TCF4, TCF5, TCF6) and Costs (TCF3, TCF5, TCF8, TCF9, TCF10, TCF11). Their grouping would provide a general picture on the guidelines for research needs, investment priorities and regulation necessities for removing obstacles, which altogether represents the required further steps in this research.

THE CAUSE-EFFECT METHOD USED IN HIGHLIGHTING THE MAIN CAUSES AND IMPLICATIONS OF MARITIME ACCIDENTS IN THE BLACK SEA

Abstract: Maritime transportation is a complex activity both in terms of the volume and nature of the shipped goods, but mostly in terms of the particular operational conditions, as the seas and oceans impose special measures for the safety of the ships. In the field of the maritime transportation, people interact with technology, the environment and organizational factors, each of them has a determining role in the safety of the ship in the sea. As regards the Black Sea, this is a great inner, and the wave area is much smaller in terms of its extent than in the open ocean. As a consequence, the average wave conditions are generally less energetic. However, strong storms, which are characteristic of the region, can generate large waves in the Black Sea with high wave heights comparable to the ocean waves, which can lead to accidents on the sea. The causes of the marine casualties and their effects are constantly investigated by international organizations such as United Nations and European Comision, as well as by specialized agencies such as International Maritime Organization (IMO), International Labor Organization (ILO), which have developed a number of conventions, regulations, rules and international standards to reduce the frequency or even to eradicate the marine accidents in the future. Among the causes that can generate marine casualties, the following should be taken into account: high traffic density, bad weather conditions (storms, waves, precipitation, frost), navigation barriers, sea conditions (sea depth and seabed), low visibility, human errors, hidden ship vices, gas emissions in tanks, which may separately or occurring with other factors, result in shipwrecks. The present work aims to present how to use the cause-effect method can highlight the major causes and their secondary causes with disastrous effects in terms of loss of lives, material damages and environmental pollution.

Keywords: Black Sea, maritime transportation, marine casualties, cause-effect method, sea conditions.

1. Introduction

World economic growth in the recent years has led to an increase in the foreign trade and, implicitly, of the global maritime trade. Starting from the fact that the production of the accidents in the sea is inevitable and that they can cause pollution of the seas and oceans, the evolution of the maritime transport has been marked by a number of requirements in terms of the pollution prevention and increasing safety.

On the other hand, it should be mentioned that the maritime transport is a complex economic activity due to the particular environmental conditions in which it is carried out, which requires special safety measures, but also that the quantity of the goods shipped annually and the material value of them.

International organizations and institutions such as the UN, EC and specialized agencies such as the International Maritime Organization (IMO), International Labor Organization (ILO), which have authority with respect the regulations, procedures, techniques and materials in the shipping industry, have developed international conventions, regulations, rules, norms and international standards for safety in the sea and the prevention of the marine pollution.

The causes of the marine casualties and their effects are constantly investigated, classified, and concludes, which are then transformed into international norms or conventions to reduce or eliminate the naval accidents in the following periods (Vlasceanu, 2015; Omer, 2015).

One of the important conventions on the pollution prevention and control, which has been adopted under the aegis of the IMO, is the International Oil Pollution Response and Cooperation Convention (OPRC), which Romania has adopted in 2000 (IMO, 1994).

Another Convention on the Prevention of the Marine Pollution from Ships is the 1973 International Convention, to which Romania has joined since 1993, and which today is known as the Convention on the Prevention of the Pollution from Ships (MARPOL 73/78, 1997).

As a response to a series of major oil-related disasters, the SOLAS Conventions (SOLAS, 1974) have repeatedly changed the Conventions of the International Convention for the Safety of Life at Sea.

Also, as a result of the shipping disasters resulting in losses and severe contamination of the marine environment, the International Safety Management Code (ISM, 1993) was developed and adopted in 1993 as an integral part of the International Convention SOLAS (ISM Code, 2002; ISM Code, 2005).

Maritime safety and protection against maritime pollution are fundamental objectives which focus on a large number of programs aimed at the safe and unpolluted maritime transport.

This paper seeks to outline the main causes and sub-causes of the marine casualties in the Black Sea using the cause-effect method.

2. Types of Accidents and Categories of the Ships Involved in the Black Sea

[1] Corresponding author: stingherucristian@yahoo.com

Accidents at sea can be very serious accidents involving total ship loss, loss of life and serious sea pollution, serious accidents involving fires, explosions, failure, collision, cracks in the ship's body, etc. and less serious that does not qualify as very serious or serious accidents (Antão, P et al., 2008).
Most accidents in the Black Sea occurred during the cold season (November-March), when the hydro meteorological conditions are the most unfavorable, the strong wind, the fog, the abundant snowfall, the low temperatures that produce ice deposits on the deck and on the superstructures of the ship affects the ship's buoyancy (Guedes Soares *et al.,* 2001).
During the cold season, wind frequencies at high speeds are higher than the rest of the year. Winds at speeds of 11 and 15 m/s reach 12-25% of the total in winter, and winds with speeds higher than 15 m/s reach 10%, compared to the annual average of 3-5%.
Often the strong winds are accompanied by the abundant rainfall, low visibility, situations that may last for 13 and 45 days, which accompanied by strong frosts, increase the likelihood of the shipwrecks (Gasparotti and Rusu, 2012; Ivan *et al.,* 2012).
In the winter and in the western and northwest part of the Black Sea, due to the specific aerospace situation, permanent conditions for the production of the storms are created (Rusu *et al.,* 2014; Butunoiu and Rusu*,* 2014).
Different types of the ships seem to have different types of accidents. Containers may overturn as a result of the coupled ship movements (pitch and roll). This is more likely to occur in the seas with hard waves conditions with moderate heights, while the port container ships accidents have also occurred at relatively low wave heights (less than 4 m) (Gasparotti and Rusu, 2012; Rusu *et al.,* 2014).
In the case of bulk carriers, the accidents have been recorded in severe sea states (wave heights> 4 m). These vessels are particularly vulnerable to the accidental water inclusion. The combined load of the loaded goods and water leads to the excessive stresses in the structure of the hull, with the consequence of cracking and rapid diving off the ship (Gasparotti *et al.,* 2013; Gasparotti *et al.,* 2014).
Most of the reported accidents occurred under relatively low sea conditions (Ivan and Rusu, 2012).
In the Black Sea, known as the sea of storms, there has been a relatively large number of the naval accidents that have had unfavorable hydro meteorological conditions as immediate cause, some of which are presented below.
On January 10th, 1982, around 14:45 hour, in the conditions of a strong storm in the Romanian Black Sea coastline, the wind having 9 on the Beaufort scale from the V-NV direction, the Continental Carrier, which was marching on the Anvers-Constanţa route failed. The event took place even though the storm warnings were transmitted by the Radio coast Constanţa as early as January 9th, the commander continuing the maneuvering of the ship to be housed in the port of Constanţa. The combined of the wind and wave action reduced the ship speed by up to 80% of its nominal value and the ship became very difficult to manage.
Although the commander and the marine officers intended to keep the ship as far away as possible from the coast, where the depths are small, the ship has moved over the bottom of the water just to those places that have posed a danger of failure. In spite of the orders given to avoid the failure, nothing could be done because the ship has moved away from the inertia a considerable amount of space. In less than an hour the ship has failed at a short distance from the entrance to Midia Harbor.
Another shipwreck occurred on the night of February 28, 1984, when the Indian VISHVA SHANTI cargo ship that headed forwards the Constanta port failed. The accident occurred in the conditions of the existence of a 8-9 strong wind storm on the Beaufort scale in the N-NE direction, in the Black Sea Romanian seashore, with high waves and abundant blizzard snow, which reduced the visibility considerably. In this hydro meteorological context, plus the non-use of the appropriate nautical documents, the stress due to the fatigue and adverse environmental conditions, the ship collided with the protective pier and failed, tilting 170 degrees to the horizontal plane in less than half an hour, due to the penetration of the water through the large holes produced in the hull of the ship.
The largest shipwrecks in the history of the Constanta harbor during the storm are those of the "Sadu" ship in December 1988 and of the "Paris" and "You Xiu" in January 1995, resulting in loss of lives (Cumpănă C and Cumpănă AD, 2008).
On December 2, 1988, in the northern area of the Constanta port, the Romanian ship "Sadu" sank near the northern pier. It carried a coal transport from Constanta port to Galati. Around 13:00 that day, the 4,800 tdw ship was caught by the storm, repeatedly hit the dikes, and finally sank.
On the evening of January 4, 1995, the two "Paris" and "You Xiu" ships were caught by a strong storm. The cargo ships were empty and could not be controlled. The wind and waves hit the northern pier of the port of Constanta. The dike broke and the ships sank.
Also, due to a storm on July 26, 2007, the MULTI TRADER under the Cambodian flag sank near Venus. A few hours after the event, fuel jets have appeared on a 10 km length.
Then, on October 10, 2007, the Romanian fisherman YLDIRIMLAR-1 sank in Midia harbor, due to the unfavorable weather conditions and technical problems. The ship, with a length of 19 m, was pushed by a storm during the night while making a march from the Sulina port to the port of Midia. The ship partially sank a few hundred meters from the northern dike in the conditions of a wind speed of over 60 km/h in N-E and 5-6 m wide waves.
On November 12, 2007, the VOLGA-NEFT ship carrying more than 4,000 tons of crude oil broke in two during a storm during a stopover in the port of Kavkaz. A few hours after the incident of the Russian oil tanker, two other carrier ships carrying sulfur were sinking near the port of Kavkaz. These two accidents have had serious consequences for the marine environment due to the Black Sea sulfur pollution, both at the surface of the water and in the coastal region.
A similar accident occurred in December 2009 when a Moldovan ship was carrying fuel was broken in two by a very strong storm, in the offshore of the Russian resort Sochi.

In March 2012, there was an accident in the offshore of the Black Sea coast when a Russian ship, was drifting, collided with the REXXON oil prospecting platform, causing a huge explosion. Also in 2012, on July 13, a commercial ship with the direction of travel to Istanbul exploded at 15Km from the port of Mangalia.
Another accident occurred in the Black Sea on April 30, 2013, when a fire produced on board of the GSP Bigfoot 1, resulting in damages of the diesel generators.
In 2014, on 17 May, due to the strong wind, the anchor line was broken, with damages to the Mare Nigrum research ship. In 2015, of the 5 accidents caused by the high waves and strong wind in the Black Sea, which resulted in great damages and loss of the cargo, one of the accidents led to the destruction of a fishing vessel.
These examples of the accidents occurring in the Black Sea, show that, not only there is a high incidence in terms of the occurrence of such marine casualties, but also the fact that it is a close sea, the impact of the pollution can be higher than in the oceans.
On the other hand, the Black Sea is an important route of the navigation, which through the European transport corridor number 7 (the Danube-Rhine-Main Canal) connects with the countries from the Central Europe to the Baltic Sea.
A substantial increase of shipping is also expected in the near future, in the Black Sea due to the increase of the offshore activities generated by the identification of major oil and gas fields in the offshore (Raileanu et al., 2015).
In this context, enhancing safer navigation and reducing the risk of the accidents in these areas, which are at high risk, as they are subject to the intense maritime traffic, it is a problem that needs to be thoroughly analyzed from the point of view of the main causes leading to the undesirable events such as pollution of the environment and loss of the human lives (Modiga *et al.,* 2016, Gasparotti *et al.,* 2016).
Figure 1 shows the number of the navigation events and their severity over the period 2013-2017.

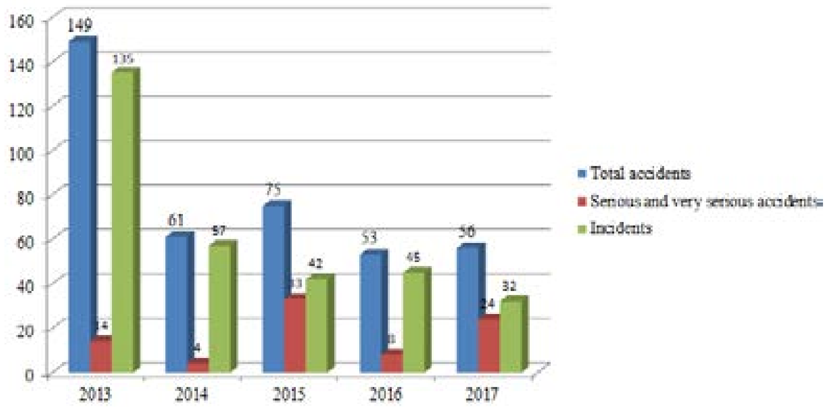

Fig. 1.
Total Number of Navigation Accidents and Their Severity Over the Period 2013-2017
Source:(Romanian Naval Authority, 2017)

Navigation accidents can occur through: collision or contact, fire or explosion, capsize, grounding, breakdown of the ship underway, stranding, and break up.
Figure 2 shows the types of the accidents that have taken place in the Black Sea between 2013 and 2017.

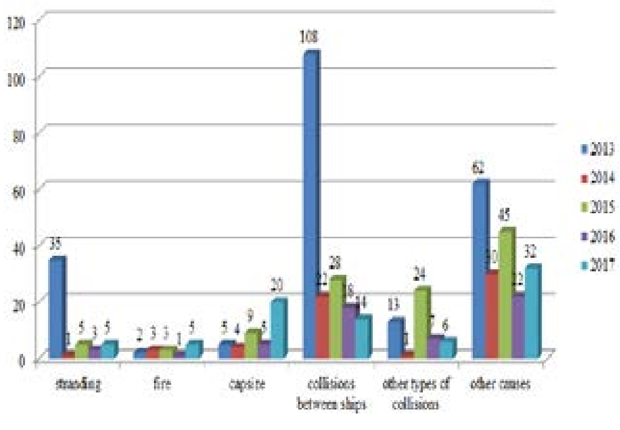

Fig. 2
Types of Marine Accidents in the Black Sea in the Period 2013-2017
Source:(Romanian Naval Authority, 2017)

Figure 2 shows that the collisions predominate and as time goes on, the number of the accidents is decreasing. Most accidents that have occurred in the Black Sea are minor accidents, sometimes accompanied by minor sea pollution.

3. Causes and Effects of the Marine Casualties in the Black Sea Basin Identified by the Cause-Effect Method

Statistical data show that the shipwrecks are caused by the sea conditions (depth of the sea and the seafloor relief on the seabed), navigation barriers, low visibility, human errors, hidden ship vices, complex technology, inappropriate operations and maintenance of the equipment, overheated machinery, inadequate spare parts, ships age, gas emissions in tanks and adverse hydro meteorological conditions(storms, waves, precipitation, frost), the latter being the second most frequent cause of the events (Toffoli *et al.,* 2005; Shuohui *et al.,* 2006). However, because there are no weather details in the databases, it is difficult to assess the exact cause of the accidents if they are caused by the fog, strong currents, high wave heights or other hydro meteorological aspects (Toffoli *et al.,* 2003). In a statistical analysis of the naval accidents in the Portuguese waters, (Gouveia *et al.,* 2007) concluded that the accidents due to the sea and hydro meteorological conditions have accounted for 23% of the total, being a major cause, after the technical failures (25%). However, the most accidents were due to the heavy hydro meteorological conditions and human errors (Milan and Gomoiu, 2008). When these two factors intertwine, the most dramatic situations occur, resulting in loss of lives, material damages and environmental pollution. Other causes may be: technological and organizational factors (Curry and McKinney, 2006). Of these other causes, according to the published statistical data, their share in producing of the marine disasters is the following: the complex technology 7%, inappropriate equipment exploitation 8%, out-dated equipment 3%, ships age 4%, human error 18%, collision with object 1%, fire/explosion 3%, cables/nets on propeller 3%, open water/cause unknown 5% (Figure 3). Referring to the human error, a study by the National Research Council of the United States (cited by Rothblum, 2006) speaks of the general technical knowledge as being the cause of 35% of the maritime accidents. In the same study, 78% of the seafarers have complained of the lack of the general understanding of the ships' system for which they work as a contributing factor to the accidents, as can be seen in the examples of the accidents in the Black Sea by not knowing the nautical and manouvring qualities of their own ship.

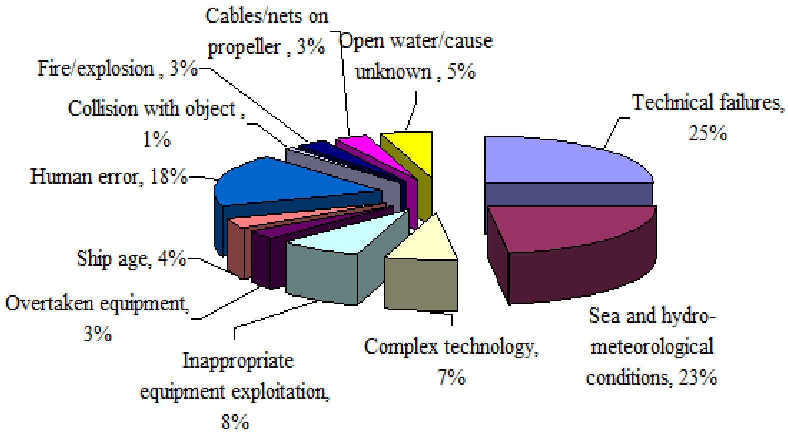

Fig.3.
The Influence of the Various Factors that Contributing to the Production of the Marine Accidents

All these causes can, individually or in combination, lead to the occurrence of the marine casualties (Milan and Gomoiu, 2008; Wayment and Wagstaff, 1999). Therefore, it can be said that the marine casualties are not produced by a single cause, but by a multitude of the causes.

Analyzing the causes of the Black Sea accidents, the main immediate cause is the unfavorable hydro meteorological conditions: storms, strong winds, high waves, often accompanied by the abundant blizzard snowfalls that considerably reduce the visibility (Rusu and Macuta, 2009). In some cases, the technical defects of the ship have been added to these harsh conditions. Alongside of these objective factors, a number of subjective factors have also emerged, which refer to the poor specialist training of the crew and commander, especially for the cases of crisis, stress and fatigue. In many of the accident cases cited, the commander did not receive or circumvent the storm warning transmitted by the Radio coast or did not use the navigation radar during the maneuvre and near the coast.

Overlapping of these categories of objective factors, mainly thunderstorms, strong winds and large waves, and subjective ones that correspond to the human errors have led to the serious naval accidents.

For the year 2017, the main causes of the marine casualties in the Black Sea were: hydro meteorological (21), technical (3), human error (22), immersing objects (13), and other causes (16). The share of these causes is shown in Figure 4.

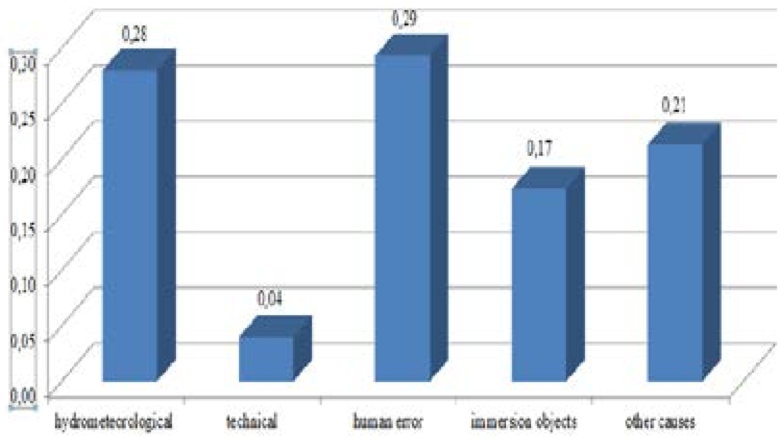

Fig. 4.
The Main Causes of Marine Casualties
Source:(Romanian Naval Authority, 2017)

In order to reduce the accidents at the sea, it is necessary to identify the causes that produced them. Starting from the causes that caused the accident, one can examine the entire chain of the events, determining the factors that contributed to its production or the underlying causes. By analyzing the underlying causes, it is attempted to understand why an accident has occurred and the circumstances of its occurrence ("what happened, how it happened", and "why it happened").
The cause-effect method provides the opportunity to identify the major causes and associated potential causes, so that the focus on the problem to be solved is done in a structured and systematic manner.
Starting from the analysis of the accidents produced in the Black Sea, an assessment can be made of the main causes and sub-causes, which have the effect of producing the marine casualties.
Considering the share of the causes leading to the marine casualties in the Black Sea, a cause-effect diagram (Figure 5) has been made, highlighting the major causes and their sub-causes.

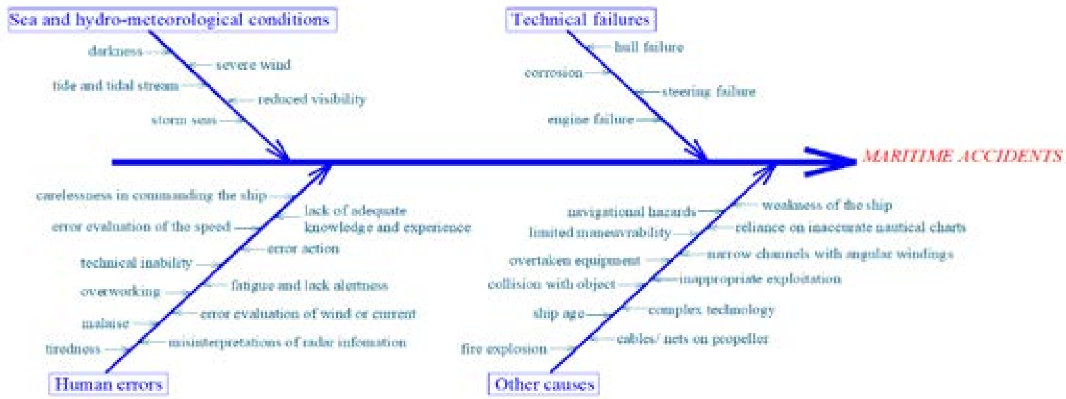

Fig. 5.
The Cause-Effect Diagram on the Maritime Accidents

The human factor is one of the main causes of the maritime accidents. Understanding the mechanism that causes the human error is the key to preventing the marine casualties.
Therefore, in order to make progress in reducing the maritime accidents, attention should be focused on the types of the human errors that lead to situations that can no longer be controlled. Identifying the types of the human errors can be done by analyzing the marine casualties and establishing how they occur.
Regarding the ship structure and naval system reliability, over the last 40 years the shipping industry has focused on improving them to reduce the accidents and increase the efficiency and productivity. Thus, a number of improvements have been made in the ship hull design, stability and propulsion systems, navigation equipment, all of which being currently highly technologically advanced and reliable. With all these advances, the rate of the maritime accidents is high, due to the fact that the structure of the ship and the reliability system are only a relatively small part of the security equation.

4. Conclusions

Marine accidents are unexpected events that may produce financial and property losses, damages, and loss of lives. The effects of these accidents can be disastrous, especially when they end with the loss of the human lives and the pollution of the marine environment.
Over time, a number of special measures have been established through the international conventions, regulations, rules, norms and international standards for the safety at the sea and the prevention of the marine pollution. Despite the international conventions and resolutions, aiming in improving the safety level, the maritime accidents remain a major concern.
The effects of these accidents adversely affect the environment, the people and shipboard activities, ranging from the minor injuries to deaths and insignificant damages to very serious damages on the environment and people's lives. The causes that can produce these marine accidents are multiple, and even if the statistics show a slow but steady decline over the last few years, they are inevitable.
The causes of the marine casualties in the Black Sea may be multiple: sea states and hydro-meteorological conditions, tide, tidal flow, strong wind, low visibility, technical defects (corrosion, steering faults, engine faults or ship's defect), conditions of the navigation routes (limited marine areas, navigation barriers, inaccurate nautical charts), age of the ship, small handling capacity, human errors (lack of adequate knowledge and experience, negligence in ordering a ship, technical inability, misconduct radar information, fatigue and lack of attention, overuse, fatigue), complex technology, etc.
All these causes, taken separately or in combination, can lead to real maritime disasters.
The cause-effect method is an analysis tool, being a suggestive model of the correlations between an effect and the causes that produced it. It provides a systematic way to look at the effects and their causes.
The problem analyzed in the method is an undesirable event (maritime accident), characterized by the risk of its occurrence, which must be diminished or eliminated, by determining the causes and sub-causes that determine it and their analysis.
The cause-effect method, based on the identification of the major causes and associated potential causes, provides an opportunity to understand how the accident occurred, what happened, how it happened and which are the main factors can be taken into account in avoiding the maritime accidents. In this way, it is possible to determine how these factors influence the occurrence of the accidents and at the same time to discover the links between the possible causes.
The advantages of using this method are: identifying the base causes, highlighting the cause and effect relationships, details about the factors that influence the production of the accident and the relationships between them, determining the areas requiring additional information that show what can be changed.

ASSESSING THE TRAFFIC RISK ALONG THE MAIN BLACK SEA MARITIME ROUTES

Vasile Rata[1], Liliana Rusu[2]
[1,2] *"Dunarea de Jos" University of Galati, Department of Mechanical Engineering, Romania*

Abstract: Motivated by the fact that numerous maritime accidents have occurred in the Black Sea, the foundering of commercial ships, but not only, aims to assess the risks that may affect commercial traffic. Considering since 2001 to present, no less than 20 ships have shipwrecked in the Black Sea and five of them in 2017, a general analysis of the causes that have affected these undesirable events is required. In order to identify as accurately as possible the external factors which affected the vessels, the main wave parameters simulated by a wave modelling system implemented in the Black Sea are evaluated, together with the wind fields over the Black Sea basin provided by the U.S. National Centers for Environmental Prediction, Climate Forecast System Reanalysis (NCEP-CFSR). Thus, for the geographical area of the ship involved in a major incident, several sets of information that preceded the event, set during the event and another set a few hours after the catastrophe are identified. By studying external factors such as weather conditions, sea parameters, can lead to certain patterns that can be identified before they occur, and that in the future these disasters in the shipping industry are to be prevented. This study is designed to prevent the loss of human lives, commodities and ships in the future, risks in terms of environmental conservation.

Keywords: Black Sea, traffic risk, weather conditions, maritime accidents.

1. Introduction

Due to the phenomenon of globalization, commodity trade has witnessed spectacular growth over the past three decades, which has led to an equally spectacular growth of the commercial vessels number. The Black Sea region was not bypassed by this phenomenon of significant increase in the number of ships designed to support the demand of products and transport services. This phenomenon is favorable because it leads to the economic growth of the regions in which it develops. Less positive parts also appear; thus, the subject of this article addresses the risks posed by shipping in the Black Sea area. Maritime safety is a hotspot in any approach due to the socio-economic implications with which it often ends (Gasparotti and Rusu, 2012).

This study was designed to show that there are real concerns about maritime activity with its implications for the safety of human life at sea, the impact on the environment and the impact of maritime accidents on the industry's prestige. The availability of meteorological information can help the ship masters to decide where to sail, and which routes to plan for their ship in order to avoid dangerous situations (Ivan *et al.,* 2012; Rusu and Guedes Soares, 2014, Rusu *et al.,* 2014a).

At the same time, due to the increase in the world fleet, there is the presumption that, vessels that have exceeded a considerable period of years in service are intentionally withdrawn in certain geographical areas. Thus, as aging ships, outdated by the technical requirements and norms in force or showing fatigue, are operating in regions like the Black Sea to make way for new ships in Western Europe (Butt *et al.,* 2013; Weng and Yang, 2015). These claims are backed up by data and industry-specific figures showing that between 2001-2011 the number of ships registered above 100GT increased by 17,000.

2. Incidents in the Black Sea

To accomplish this study, all the serious incidents which ended as shipwrecks in the Black Sea geographic area have been identified. The area chosen for the study is bounded by the Marmara and Azov seas, with which it communicates through the Bosphorus and Kerch straits. For the period 2001-2017, there were 20 incidents that resulted in ship diving or shipwrecks, with only one ship having problems with the main engine and propulsion. A total of 21 records were collected in Table 1 (see Marine Traffic; BBC News, 2017; List_of_shipwrecks; The Telegraph News, 2017; Maritime Bulletine, 2017). All of these incidents were checked from various sources to confirm the facts for each ship.

Each ship involved in these incidents was identified, and more data were collected about it. In Table 1 are presented the ship's characteristics: ship's name, main dimensions, type of ship, year of construction and flag under which it operated as well as date at which the event took place.

3. Positioning Events on the Map

Geographic positions have been identified according to the reports of each event. Thus, the approximate locations where the events occurred are represented graphically on the map of the Black Sea (see Fig. 1.). The numbering in the first column of Table 1 was used to identify each event.

It is quite noticeable that most of these events took place near to the coast, and also that events took place in the proximity of areas with the highest density of Black Sea maritime traffic (Rata *et al.,* 2017). Only 3 of the 21 cases were the result of a collision with another ship, which in turn represents only 14%. Black Sea traffic density can be a cause of accidents because of the fairly high incidence rate of the total unfortunate incidents involving ships.

Analyzing the density of accidents and geographic areas where foundering and sinking accidents occurred in the Black Sea, we can identify two critical points in which ships appear to be prone to such events occurring with material damage and in the worst cases even with the loss of human lives. These are the proximity of the Bosphorus Straits and the Kerch Strait. Also, one cannot ignore the fact that the two critical points in terms of shipwreck and sinking events are similar with hot spots, as the density of the shipping in the Black Sea area (marinetraffic.com 2017).

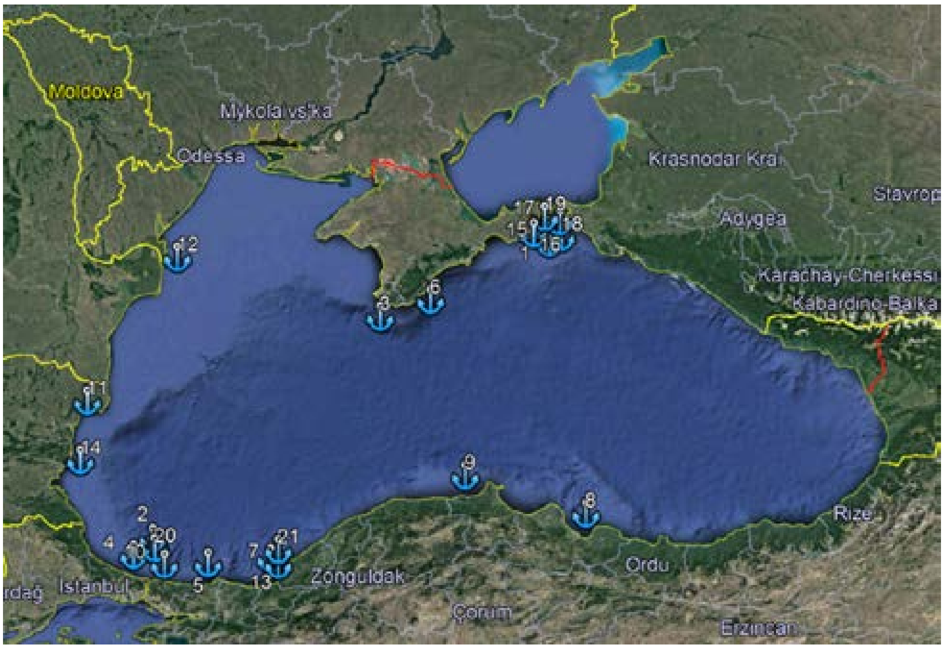

Fig. 1.
Black Sea Naval Incidents Representation From Period 2001-2017
Source: Original

4. Features of the Black Sea active fleet

It is found that ships carrying various activities in the Black Sea, especially shipping activities, are characterized as old ships. Concerned thing is that a considerable part of the ships that perform their service in this geographical area were built in the '80s,' 90s, but not only a few are built in the '70s, and even some of them were launched to the water by '60s (Rata, 2017).
The problem of these ships is a rather complex one, given the building criteria that are no longer up to date in many cases, the poor equipment of these ships due to the reduced operating budget, and last but not least the skill level of the ship's crew who often in these cases it is doubtful (Butt et al. 2013). All these things only come as a complement to the primordial factors, namely the technical and mechanical nature, the structural resistance of these ships being seriously affected during the 50 years of exploitation. Elements of maximum importance, reaching a degree of fatigue may endanger the safety of the ship at any time and to the most sensitive external factors: wave, wind, sea currents, but generally at wave that periodically apply mechanical stresses to the ship and she is acting like a metal beam under its own weight at the variable points indicated by the wave's peak (Domnisoru *et al.,* 2014).

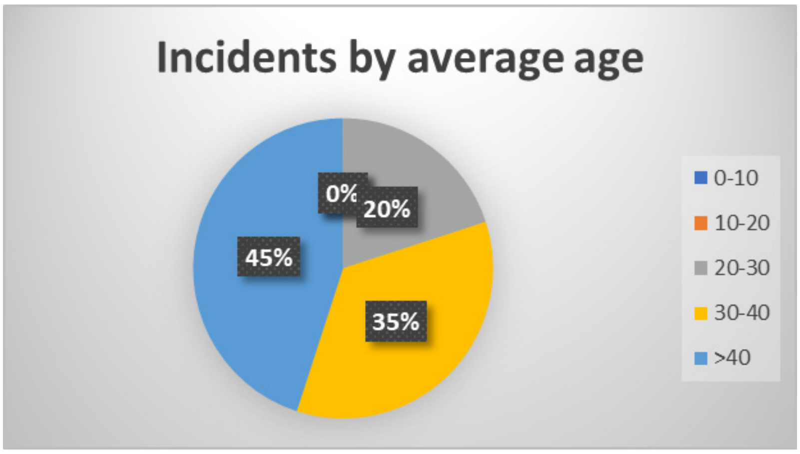

Fig. 2.
Percentage by Ships Age Intervals Involved in Naval Accidents 2001-2017, Black Sea
Source: Original

The risk according to the period when ships involved in serious shipwrecks was assessed and the results are presented in Fig. 2. It can be observed, at least in the case of the Black Sea, that the ships built no more than 20 years ago were not involved in the type of events studied in this study. Instead, the most impressive percentage, namely 45%, is represented by the ships built more than 40 years before the incident happened. Second place in this top is the range of 40-30 years

with an incidence of 35%, and the 3rd place of the podium is represented by the interval of 30-20 years with a percentage of 20%.
These results show that this causality is closely related to the time of ship build. Even the percentages thru their size show clearly the influence of the vessel's age on the possibility or risk of involving a ship in a severe naval event.
Figure 3 shows the evolution in time of the average age of vessels involved in naval accidents in the Black Sea perimeter, so we can see the increase of nearly 20 years in a period of 16 years, 2001-2017. This information leads to the idea that newly built ships are better suited to current safety requirements in operation, which is a gratifying thing. It is also underlined that in operation there are also a number of ships that were prone to a high accident risk since 2001, by a simple formula of calculation the difference of 16 years in time and the 20 years of increasing the age of ships involved in the latest accidents, leads to the idea that ships involved in accidents are largely part of the same build generation.

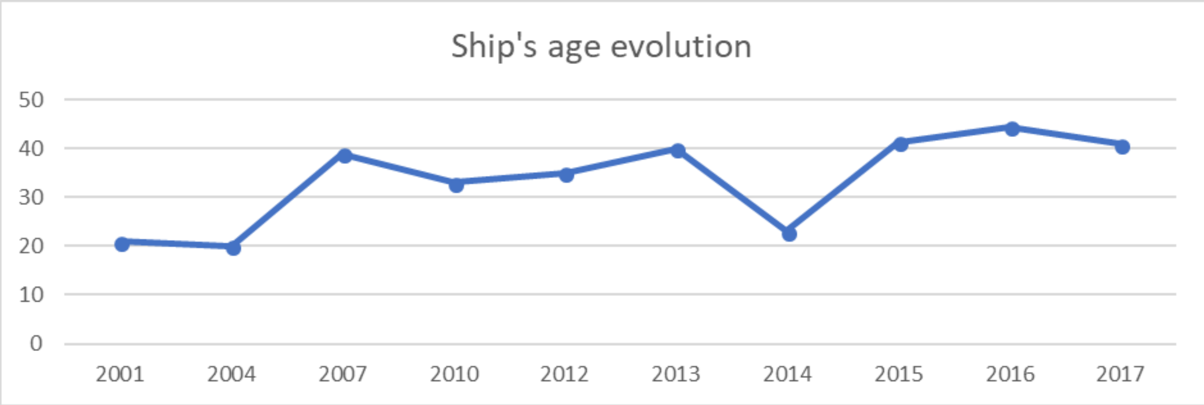

Fig. 3.
Average Age Evolution of Ships Involved in Naval Incidents 2001-2017, Black Sea
Source: Original

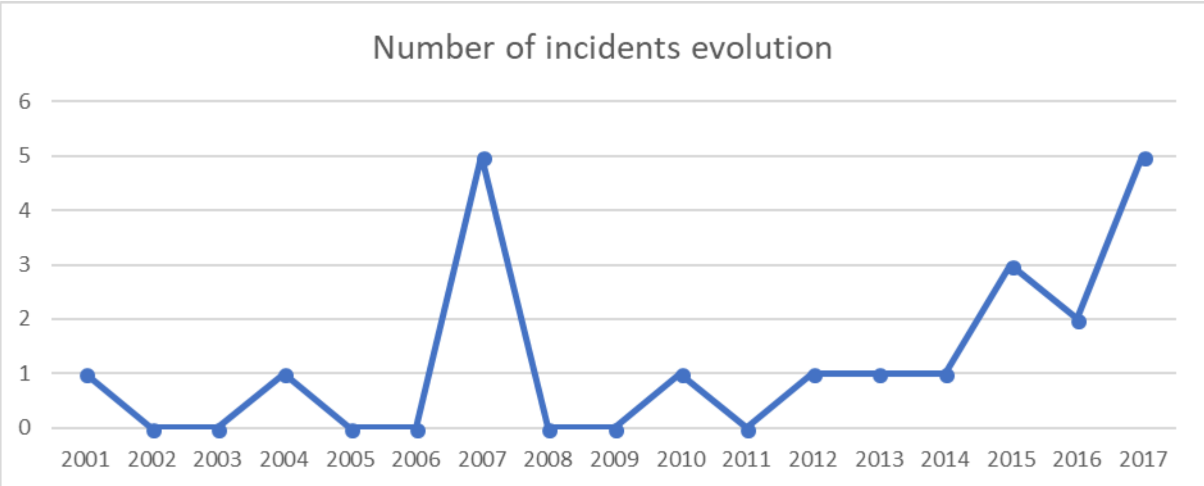

Fig. 4.
Annual Volume of Naval Incidents 2001-2017, Black Sea
Source: Original

Having reference information Fig. 3 and Fig 4., which show the evolution of the age of vessels involved in shipwrecks over time and the incidence of these undesirable events, it can be noticed that a growing number of ships built in the same generation, of the '80s, begin to emerge from use through a form that is not managed at all, and without attempting to limit the catastrophes that have resulted in human casualties, material damage and devastating impact on the environment.
Fig. 5. shows graphically the distribution of ships involved in the naval incidents listed in Table 1 by ship type. This graph shows that the most prone ships to be involved in an accident are the Cargo type. Cargo ships occupy the first place with over 80% of all ships involved in accidents during 2001-2017. Bulk carriers are ranked second with a smaller percentage of 9 percent, followed by technical and military vessels with 5 percent.

5. The Natural Factors That Lead to Accidents in the Black Sea

The vessel in the middle of the sea is affected by various external parameters, important forces that radically influence the ship's behavior on the water. The most important parameters developed by nature that have a direct influence on navigation are: wave height, wind speed, wave period, wave length, and the direction in which all these factors act on the ship.
The seasons generally dictate the average of the values of the external factors parameters, so we can observe the distribution of the accidents studied in the four seasons that take place over a calendar year. Thus, in December-February, in the winter season, it appears that occur 24% of the annual accidents, this value being reported over the entire 16-year period, 2001-2017.
In March-May, only 14% of the nautical accidents were recorded, leading to the remark that during the spring period, the density of marine accidents is reduced in the geographical area of the Pontic basin. Taking into account the values in the chart in Fig. 6. and in the summer season, the incidence rate is similar and reduced as in the spring season with a value of 14 percent.
In the case of the fall season, there are reported most of the incidents studied according to Table 1, so it can be seen how the percentage of 48% leads the autumn to first place between the four seasons that are highlighted in the climate of the region of the Sea Black.
At the same time, the results can be coupled with accident density, such as the autumn-winter seasons, resulting in a 72% accident risk, and the period with fewer number of accidents is spring-summer, adding up to a total of 28%.

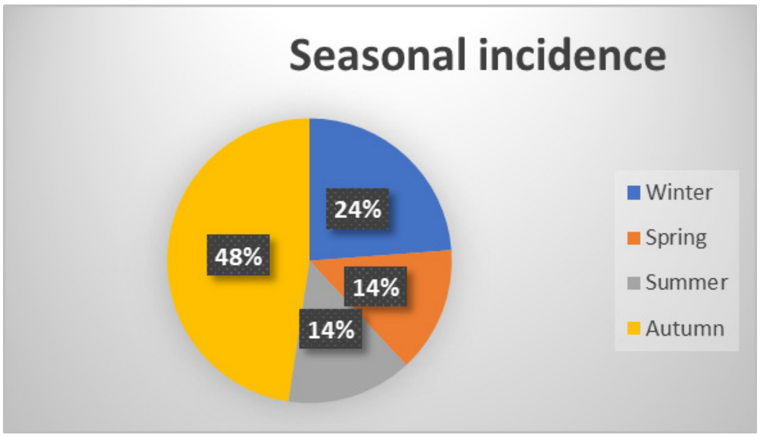

Fig. 6.
Seasonal Incidence in Percentage of Maritime Accidents 2001-2017, Black Sea
Source: Original

These things lead to the hypothesis that the sea is generally more violent by wave and wind parameters that act on sailing in the Black Sea region. In order to highlight the action of the parameters that influence the ship's behavior on water, in a rough sea, the wave conditions of the entire Black Sea basin were numerically simulated using wind re-analysis data provided by the United States National Centers for Environmental Prediction, Climate Forecast System Reanalysis (NEAP-CFSR) (Saha *et al.,* 2014). The wind fields were used to force the wave simulation model, SWAN (model of Simulating WAve Nearshore, Booij *et al.,* 1999). Thus, for each incident, the wind and wave conditions were

simulated for a period of 48 hours with a temporary increment of 3 hours. The wind speed is 10 meters above sea level and is marked with U10 (m / s). The other parameter of interest for this study is the significant height of the wave marked with Hs (m).
Thanks to the historical data base, the simulations could only be performed in the period 2001-2016, so of the 21 incidents mentioned in Table 1, only 16 events were checked for the condition of the sea, the ones which can be identified both in Table 1 and in Table 2 with numerical values ranging from 6 to 21.

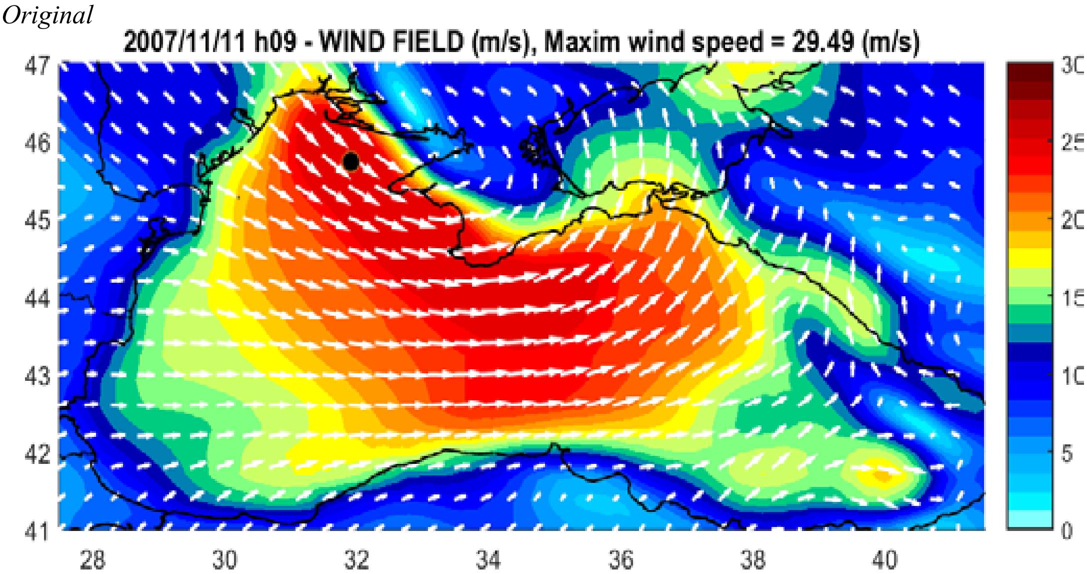

Fig. 8.
Spatial Distribution of the Wind Field and the Wind Direction Over the Black Sea (11.11.2017)
Source: Original

The results from the numerical simulation program were analyzed for each case, resulting in a series of graphical representations depending on the parameter chosen for the indicated time coordinate, as in Fig. 7. and Fig. 8.
They will be taken as an example of the embodiment of Table 2, a table in which the maximum value of the wave height was identified and noted on the second row, and the third the maximum value of the wind speed. The maximum values of these parameters were identified because it was considered the worst case, with the corresponding accidents being identified in Table 2 with values between 15 and 19.

Table 2
Wave and Wind Parameters of Black Sea in the Moment of Happening the Naval Accidents 2001-2016

No.	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
Hs[m]	1.5	1.5	1.5	3.5	5.5	5	2.5	5	3	13	13	13	13	13	8.5	6
U10[m/s]	10	9	7.5	15	18	15	12	17	15	29	29	29	29	29	22	20

Source: Original

According to the data in Table 2 it follows that not all incidents were influenced to produce the sea state disaster, because for ships with length (L) higher than 60 meters in height, the 3 meters height of the wave is not a danger for a ship designed to navigate at least in the coastal area. Also, U10 wind speeds below 15 meters per second are not critical values that would normally disrupt sea navigation activity. Such levels of the two parameters could adversely affect the activity of a vessel for inland navigation, since design criteria were not designed to respond effectively to such conditions.
According to Fig. 9., result that only a part of the incidents, for which there existed data and where the numerical simulation of the sea conditions was done, were radically influenced by the state of the sea. Moreover, 62% is not a percentage to be ignored, being quite important. Only for 25% of the cases studied can be considered that the environment was not a decisive factor for the accident. Only 13% falls within the uncertainty range due to the boundary values of the wave and wind parameters studied.

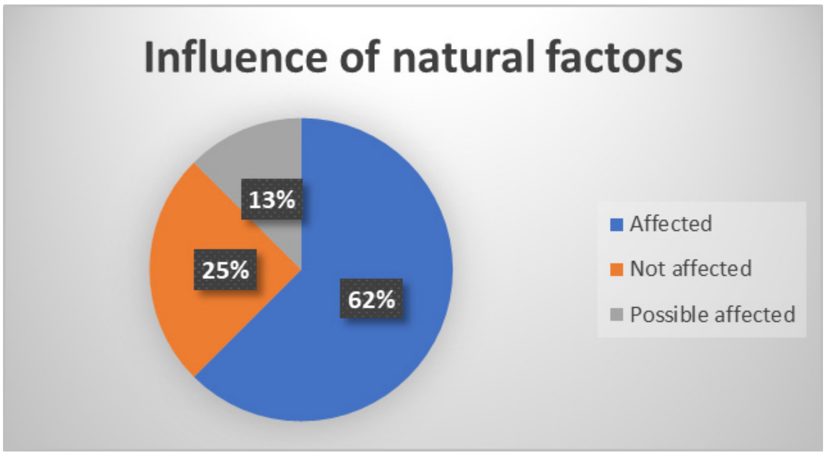

Fig. 9.
Influence of Natural Factors on Maritime Accidents 2001-2017, Black Sea

6. Conclusions

Due to the incidents that occurred during the period 2001-2017 in the Black Sea geographic area it was necessary to study the risk of occurrence of foundering and sinking events in order to identify the patterns that lead to the production of these tragic events. Such incidents are described as tragic events, because they often result in loss of human life, the effects of a shipwreck in addition to the economic ones that result from the loss of the ship or the cargo carried, it is also necessary to be mention those that negatively affect the environment. Following a shipwreck or sank, a number of pollutants result, which affect the natural ecosystem of the area through a series of polluting agents, among which can be remembered the ship's hydrocarbon spillage (Rusu, 2010) but also biological pollution with invasive organisms transported through of ballast tanks (Rata *et al.,* 2018).
An upsetting alarm signal may be drawn on the characteristics of the active Black Sea fleet that is already aged, and above all, there are prerequisites for greater aging from the perspective of migrating older ships to the East, creating space for world fleet growth, involve the introduction of new vessels in Western Europe into navigation. This factor, in an alarming way, dimension the risk of present and especially future shipwrecks occurring in the geographical area bounded by the Black Sea shores.
Complementary to natural conditions and characteristics of vessels operating in the Black Sea, human factors dictated by economic conditions imposed on these low-cost shipping services, as shipowners generally choose to use a very old ship, as example this study where the average age of ships involved in severe accidents is 37.3 years. As sum of the participating factors are considered the age of the ship, which brings with it problems of structural resistance due to the fatigue resulting from the use, the construction rules of the ship that are no longer topical, the systems that are not of the best quality and are not, an optimal state of operation, last but not least, the quality of crew skills that for various reasons fail to correctly interpret the data provided by the onboard systems.
There is an increasing trend over the past years in the number of maritime accidents.
A non-negligible factor is the new and continually changing conditions with which ships interact on established maritime routes due to climate change, which take place more often and are more pronounced in the last 30-40 years in the studied geographic area both through the duration and the intensity of the storms (Rusu *et al.,* 2014b, Lin-Ye *et al.,* 2018) that are born and developed in the Black Sea.

THE FAILURE ANALYSIS OF HANDLING PROCESS IN MARITIME CONTAINER TERMINAL

Florin Rusca[1], Eugen Rosca[2], Mihaela Popa[3], Aura Rusca[4], Mircea Rosca[5]
[1,2,3,4,5] *University Politehnica of Bucharest, Faculty of Transports, Department Transports, Traffic and Logistics, Romania*

Abstract: The logistic chains used for supply activities in industrial processes use in most cases maritime containerized shipments. It is important to ensure a shorter transit through sea terminals. The waiting time is influenced by the movements of the means of transport (ships, trucks, trains, etc.), but also by the handling and storage capacity of the terminal. In the case of the last ones, the reliability of the handling equipment is extremely important in assessing the negative effects induced by the poor reliability of the handling equipment. Quantification of these can be done by using a simulation model. For the modeling of the containers flow in the terminal is suitable a discrete process model that allows the topological attributes of the terminal, the terminal's processes and to the capacity storage limitations to be modeled. A discrete simulation model adapted to a container terminal has been developed, based on which one can estimate the additional delays that occur in the case of a failure in the container handling process in the terminal area. Different scenarios for the moments of occurrence of malfunctions of equipments inside the terminal leading to a failure in the handling process are considered. The results are suitable for terminal administration in sustaining the acquisition of new equipment to support operations in the terminal.

Keywords: maritime container terminal, discrete simulation model, reliability.

1. Introduction

The most of the logistic chains with maritime components use containerized transport. In this case, the container terminals located inside the sea ports area ensure the transfer between the terrestrial network and the maritime transportation. The main operations performed inside of these are handling and storage processes. The proper functioning of handling equipment can influence the processes inside the terminal with effects on the entire logistic chain. Such an example can be represented by the failure of a quay crane which may lead to delays in the loading/unloading process of vessels, usually quantified in penalties paid by the terminal administration. Thus, it is important for the terminal administration to carry out an analysis of the probability of failure and of the impact induced by the unavailability of the handling equipment. According to (Steenken, 2005) the decision-making process in container terminals is carried out on three decision levels:

- Terminal design stage (terminal structure, connection with transport networks, selection and dimensioning of handling equipment, etc.);
- Operative planning stage (berth allocation, stowage planning, crane assignment, stowage area design, storage policies);
- Operative stage (internal transport in the terminal, allocation of containers in the storage area, scheduling of handling equipment).

In the case of the analysis of the reliability for a maritime container terminal, it is required to select the operative planning stage, because the consequences of under sizing the number of handling equipment in relation with the container flow size are always identified on the second decision level. The problem is caused by the lack of correct information about the situations that may occur in exploitation. Thus, the variation of the number of containers transiting through the terminal leads over time to non-uniform request of the handling equipment.
Also, the arrival of maritime ships is extremely difficult to predict, those being conditioned by a series of limitations that are not related with the activity of the administration of the container terminal.
To cope with such uncertainties, it is desirable to use a discrete event simulation software in which to build up the logical model of handling and storage activities inside the terminal (Rusca& all, 2016a). This is developed taking into consideration the topological attributes, the hierarchy of the processes within the terminal, respectively the capacity limitations of the handling equipment and storage area. In addition, for handling equipment, the mean time to failure and recovery required for handling process analysis can be modelled. The inbound and outbound container's flows in the terminal are dependent on the vessels' arrival times in the port, respectively on other transport means arrival' times from terrestrial network.
The inbound and outbound container's flows in the terminal are dependent on the vessels' arrival times in the port, respectively on other transport means from terrestrial network arrival times.

2. The Development of Approach for Failure Analyze

The paper presents the results of the research on the activity of container terminals located within the seaports. The measure of performance for the handling and storage processes are influenced both by the topological structure of the terminal and the non-uniformity of the inbound and outbound container flows from terminal as well as by the good

[1] Corresponding author: florin.rusca@upb.ro

functioning characteristics of handling equipments (cranes, transtainers, reach stackers, etc.). The malfunction of these equipments could influence the activity inside the terminal. The use of discrete modeling for maritime terminal activity represents an evaluation method of the critical areas inside the terminal (Angeloudis& Bell, 2011), (Kotachi& all, 2013), (Lin& all, 2014). The container terminal is considered to be a queuing system. Unlike the previous modelling models for bulk or RO-RO terminals, the present research has taken into account the logical hierarchy of the terminal operations, respectively pointed out the role of the storage area for the transit of containers from sea vessels to the terrestrial network (Dinu& all, 2017), (Ianone& all, 2016), (Özkan& all, 2016), (Rusca& all, 2016b).
The second stage of the research is represented by the assessment of the operational risks that may occur in the terminal activity. These are generated by a series of factors related to the sizing process of the storage area or handling equipment in relation with the size or the structure of the container flows (Rusca& all, 2015). Also, the failure of handling equipments causes a series of risks that may affect the operations that take place inside the terminal. A number of random functions were used to obtain possible values for reliability of handling equipment inside the terminal. Setting acceptable limits for risks, assessing actual risk levels and predicting the balance of cost/benefits for proposed safety measures are all meant to assist the risks management process (Monnier & Gheorghe, 1996).
Finally, using the simulation model developed at the first stage one has been analysed the impact of the failure for this kind of equipment on the terminal activity (fig. 1).

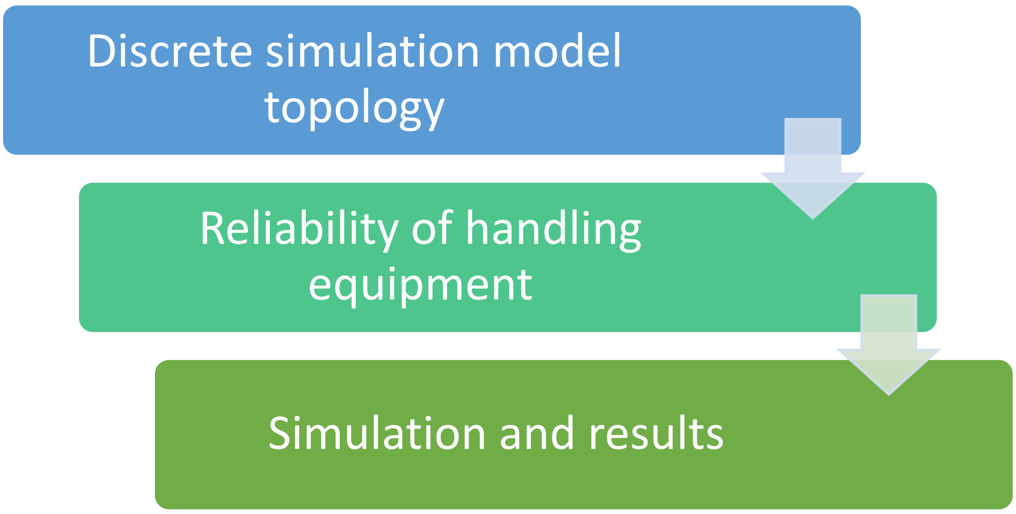

Fig. 1.
Approach used for failure analyse

3. The Simulation Model with Component for Malfunction Event and Repair Process

The discrete simulation model is made taking in consideration the topology of a Romanian Container Terminal (SOCEP SA). The simulation support is ARENA 12 simulation software. The model structure is organized in five sub-models:

- the arrival process of maritime vessels (Figure2),
- the arrival process of land vehicles (trucks) (Figure 3),
- the unload process of containers from vessel to the storage area (Figure 4),
- the load process of containers from storage area to vessels (Figure 5),
- the malfunction (failure) event and repair process (Figure 6).

In the first of them is simulated the arrival of vessels to quay. This is in accordance with a repartition function (Exponential, Poisson, Erlang, etc.) or may be according to a certain schedule of arrivals in the port, when the data could be provided. For every ship are generated two variables: first is the number of containers which will be unloaded, respectively the number of containers to be loaded on maritime ships. One ship occupies the quay and releases it when it receives a signal which confirms that the process of unload-load containers is finished.

- The arrival process of maritime vessels (Figure2).

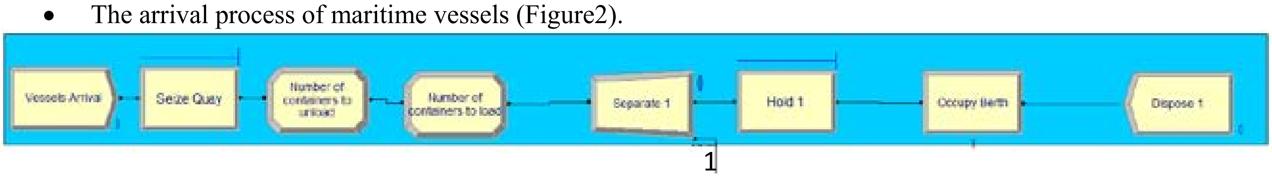

Fig. 2.
The sub-model for simulating vessels activities inside the terminal

In the second sub-model are simulated the activities of land vehicles. These can be trucks or trains. For the analyzed terminal, the rail network ensures a connection with the maritime container terminal, but the volume of inbound-outbound containers it is low, so the rail transportation is not considered hereby. But if it is necessary the model can be improved with a new module for this connection. For trucks one considers three possible situations: (i) unload a container; (ii) load a container or (iii) both of them.

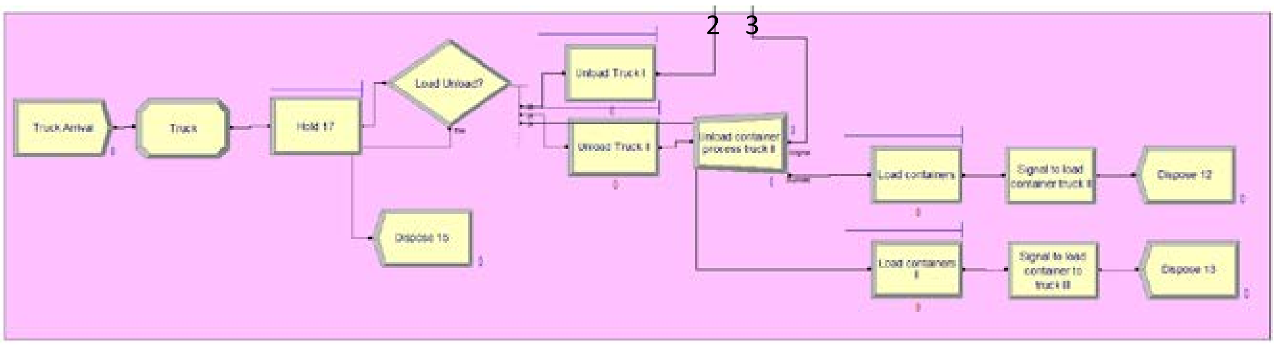

Fig. 3.
The sub-model for simulating trucks activities inside the terminal

In the third sub-model is simulated the unload process of containers from maritime vessel. This is made using one of the two existing quay cranes. For every container two proofs are made: if there are free slots in the storage area and if all the containers from the ship are unloaded. When the second the second condition is "TRUE", the unloading process is finished and the loading process can start. The containers unloaded from maritime vessels are separated in two parts: one contains the containers with destination in the hinterland and the other one contains containers which must be loaded on other maritime vessels. In some cases, the command of the ship can require the reorganization of the containers on the ship, but this is a particular case and it is not taken in consideration because data about the rhythmicity of these activities are not provided.

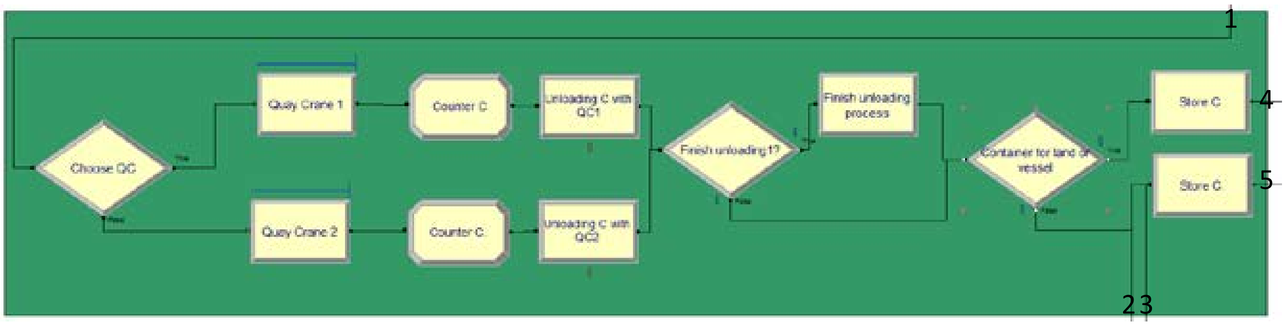

Fig. 4.
The sub-model for simulation of unload process of containers from maritime vessels

In the fourth sub-model is simulated the load process of containers from the storage area to maritime vessels. The same two quay cranes are used. If the number of containers loaded in the ship converges to the variable generated in the sub-model I, the process is finished and a signal it is sent to the vessel to release the quay for the next vessel. The number of containers in the storage area is increasing when we have the unload process from vessels or from trucks and is decreasing when we have the load process of vessels or trucks. In the storage area there are two separated zones, one is for containers from vessels with destination in hinterland and one is for containers unloaded from trucks which must be loaded to vessels. Also, in this last zone are found some containers unloaded from maritime vessels, but which must be loaded on other maritime vessels.

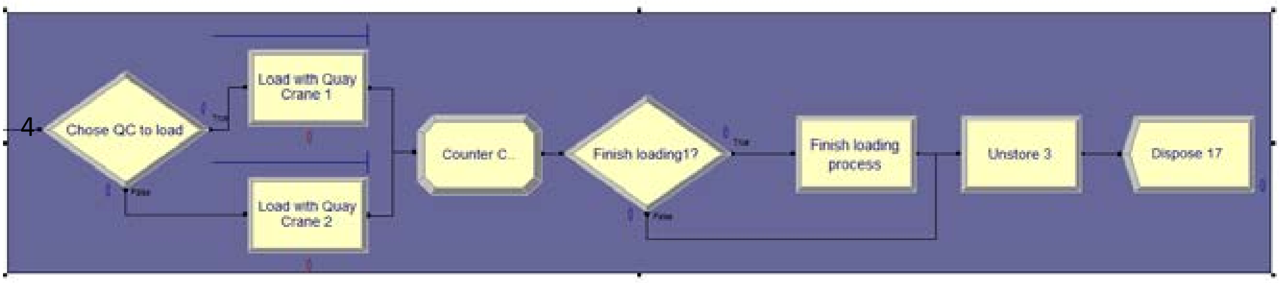

Fig. 5.
The sub-model for simulation of load process of containers to maritime vessels

The handling equipment failure is simulated in a separated model. Using a Weibul reliability function it is assigned a value for a malfunction test variable which is used in the main model to test if the quay crane is available. In case the test of malfunction return “FALSE” as value for availability of handling equipment, value 0 is assigned for malfunction test variable. After the period required for the repair process, the malfunction test variable will be associated again with the normal value 1.

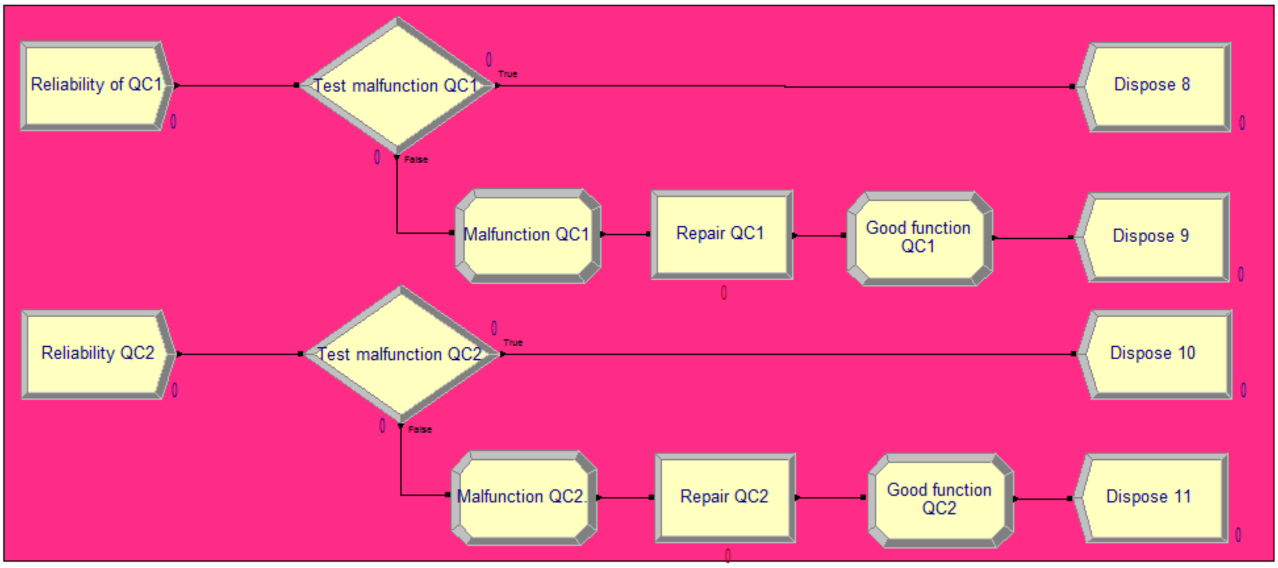

Fig. 6.
The malfunction event and repair process

4. The Failure Analyze of Handling Equipment Using Simulation Model

For the case of a Romanian maritime container terminal (SOCEP terminal from Constanta Port) the simulation model is used to evaluate the influence of malfunction of handling equipment over measure of performance for the activities carried out inside the terminal. The analyzed handling equipment is the quay crane used for unloading/loading the containers from/to maritime vessels. For the handling equipment different cases are defined, in correspondence with previous studies (Azimi& Ghanbari, 2011):

- idle time: the equipment has no demand (occurs frequently in the transitory regime at the beginning of the simulation),
- busy time: the equipment is used for containers unload or load activities,
- waiting time: the equipment is waiting for a free slot in storage area,
- down time: the equipment is out of service.

For the last case, in our simulation the mean time to failure of handling equipment follow a Weibull distribution $W(\beta,\alpha)$ where α is a shape parameter and takes the value 1, and also indicates a constant value in time for failure rate, respectively β represent a scale parameter and is used in two hypothesis (β=3 or 5 days).
The main run characteristics:

- the number of independent replications: 10,
- the warm period: 20 days,
- the simulated period: 6 months,
- the vessels arrival rate: exponential distribution ($E(\lambda)$) with λ=20, 25, 30 or 35 hours
- the capacity of storage area: 10000 TEU,
- the number of quay cranes: 2 cranes with serving time according to a triangular distribution with 3 minutes for lower limit, 4 minutes for mode and finally 5 minutes for upper time,
- the number of handling equipment inside the storage area: 10 reach stackers,
- the destination of containers from vessels: 90% to land network and 10% to other maritime vessels,
- the number of containers on vessels: normal distribution with μ=300 containers and σ=30 containers,
- mean time to repair quay crane: normal distribution with μ=6 hours and σ=0.5,
- the trucks arrival rate: constant 3 minutes,
- the trucks activities inside the terminal: 33% unload a container, 33% load a container, 34% first unload and after load a container.

Considering the hypothesis previously presented for input data, 12 scenarios are used for simulation model and the results are presented in Table 1. The simulation results provide a set of parameters useful for terminal administration in the decision making process. From these, in our research, we retain the following variables:

- number of vessels, trucks and containers used in simulation,
- occupancy ratio of quay,
- utilization ration for handling equipment,
- waiting time in queue for vessels to enter at berth,
- number of vessels in queue,
- the duration of unloading/loading process.

12	E(35)	W(3,1)	130	106100	0.750	0.930	0.901

Table 1 (continuation)

The average value for exit data from simulation model

	Vessels arrival rate	**Failure distribution for Quay Cranes**	**Utilisation of reach stackers**	**Vessels waiting time to enter to berth [hours/vessel]**	**Unloading/loading process [hours/vessel]**	**Number of vessel in queue**
1	E(20)	No failure	5.84	64.9	18.78	3.08
2	E(20)	W(5,1)	5.41	126.5	19.43	6.54
3	E(20)	W(3,1)	5.40	236.3	26.73	11.68
4	E(25)	No failure	6.25	47.1	18.49	2.07
5	E(25)	W(5,1)	4.14	176.3	24.76	7.29
6	E(25)	W(3,1)	4.73	215.4	26.21	9.47
7	E(30)	No failure	6.25	20.1	17.88	0.66
8	E(30)	W(5,1)	6.19	39.8	23.08	1.20
9	E(30)	W(3,1)	4.41	81.5	27.21	4.66
10	E(35)	No failure	6.26	18.5	17.64	0.48
11	E(35)	W(5,1)	6.21	22.2	22.03	0.56
12	E(35)	W(3,1)	5.78	62.8	24.58	1.88

In the 12 scenarios for which the simulation was made, it was considered the impact assessment of the handling equipment failure over the measures of performance regarding the activities developed inside maritime container terminals. Thus, four hypotheses on the arrival of maritime vessels in the port area were analysed. These ones correspond to some exponential distribution functions with mean (20 hours, 25 hours, 30 hours and 35 hours. For each of these hypothesis, has been simulated the situation in which the quay cranes are operated without taking into account their probability of failure. In order to assess the influence of the failure of handling equipment was considered a failure rate following a Weibull distribution and a duration of the repair process according to a normal distribution.
The system is tested for the biggest values of vessels arrival rate. These are specifically chosen respecting our goals to evaluate the influence of malfunction of handling equipment when the maritime container terminal is facing with an intense activity. The results show an increase for number of vessels waiting in queue when the arrival rate λ decrease from λ=35 hours to 20 hours. This varies from a average value 0.48 (no failure of handling equipment and vessels arrival rate is Exponential with λ=35 hours) to 11.68 for average number of vessels in queue when for mean time to failure is taken W(3,1) distribution and vessels arrival rate is Exponential with λ=20 hours (Figure 7). The highest increase in the number of vessels in the queue is recorded when vessels arrival rate is Exponential with λ=30 hours and mean time to failure follow W(3,1) distribution, with an increase by six time of number of vessels in queue (Figure 8).

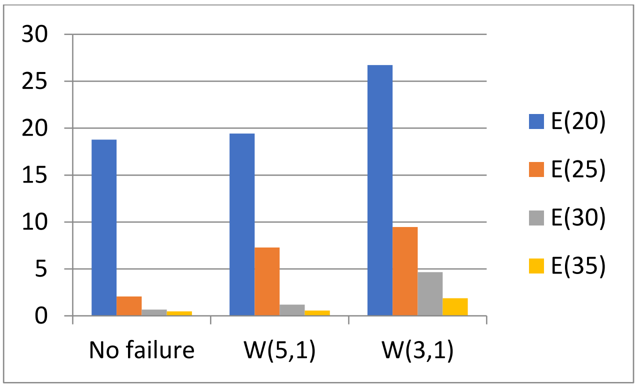

Fig. 7.
The number of vessels in queue

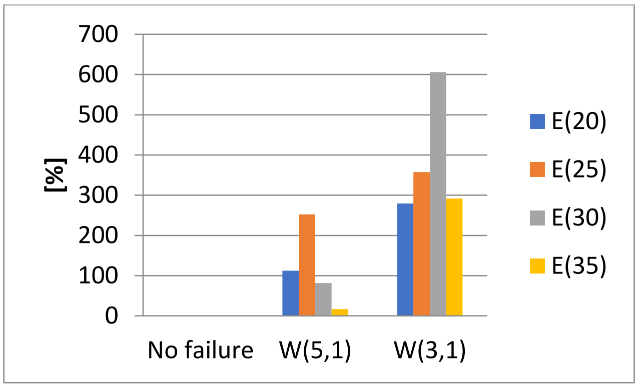

Fig. 8.
The variation of vessels number in queue

In case of average waiting time for vessels which enter at berth serving maritime containers terminal, the variation of values is between 230%-360% for all four input hypotheses when mean time to failure follow a W(3,1) distribution. A particular situation is recorded for malfunction according to a W(5,1) distribution when for a vessels arrival rate according to Exponential distribution function with λ=25 hours, waiting time have an increase with 273%, more larger in comparison with other results, which are approximatively 90-100% (Figure 9). The duration of process for unloading/loading containers on vessel is also influenced by malfunction of handling equipment, so as in case when the simulation does not include a down time for equipment, the vessels waiting time is 17-18 hours/vessel, in case of a mean time to failure according to W(3,1) distribution, they raise approximatively with 40-50% (Figure 10).

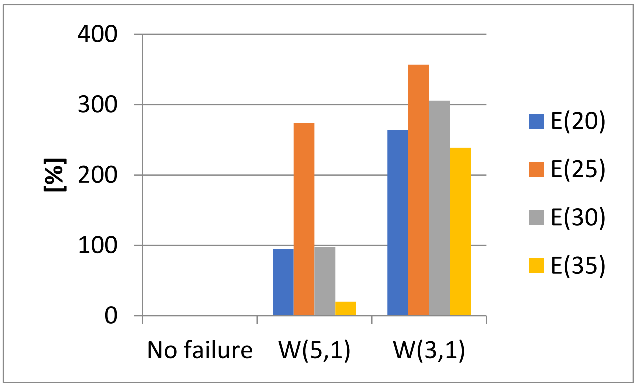

Fig. 9.
The variation of waiting time of vessels in queue

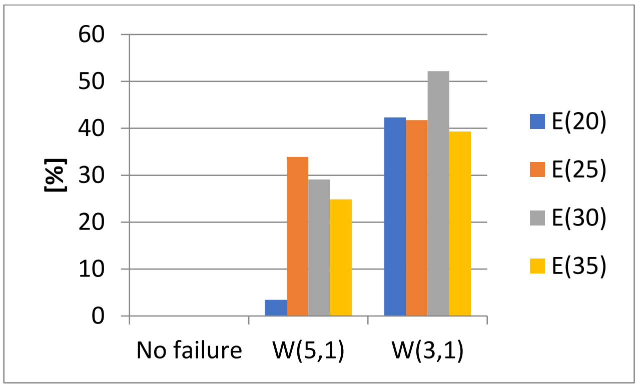

Fig. 10.
The variation of duration of vessels unloading/ loading process

3. Conclusion

The simulation model is developed using the topology, the number of equipment and the storage capacity from a real maritime container terminal. The simulation hypotheses are chosen to identify the critical thresholds when the quality parameters of the activities developed inside the terminal are influenced by the malfunction of handling equipment. The hazard event for handling equipment is estimated according to a Weibull distribution and for repair period of time is used a Normal distribution. If the duration of vessels unloading/loading process does not have a large variation (only 40-50%), the waiting time of vessels in queue for free berth have a large variation to approximately 200-300%. This variation is also influenced by the increase of the arrival rate corresponding to a time interval of 35 hours to only 20 hours between vessels according to Exponential distribution.
These results are useful for terminal administration to evaluate the importance of handling equipment replacement process when the reliability function reaches a low value with influence over the quality parameters of the activities developed inside the terminal. The simulation model can be adapted to all kind of container terminals and used together with predicted vessel traffic in the decision making process at design or operative planning stage.

ENVIRONMENTAL REGULATIONS ON AIR POLLUTION AS A DRIVER OF INNOVATIONS IN SHIPPING

Magdalena Klopott[1]
[1] *Gdynia Maritime University, Department of Logistics and Transportation Systems, Poland*

Abstract: The dynamic increase in maritime trade during the last few decades caused a significant growth in air emissions from global shipping. In order to address this negative impact on the environment, a range of regulations governing the shipping industry's environmental performance have been developed in recent years at the international and regional levels. Relying on a desk study research, this paper aims to present the relationship between these new, strict emission requirements and the emerging innovativeness in shipping industry. Indeed, the shipping industry responded with new, innovative technologies (e.g. exhaust gas cleaning systems, alternative energy sources, including LNG propulsion systems), which are briefly elaborated. It is believed that in a long term these innovations are essential for achieving more rigorous environmental goals in the future, minimising the cost of compliance and thereby delivering competitive benefits. The background to these considerations consists of: a) a general introduction to the problem of air pollution from maritime transport and their influence on human health and life as well as the environment; b) a short review of literature concerning the impact of environmental policy instruments on companies' innovation-driven activities and competitiveness; c) a characterisation of the environmental regulations on air pollution from ships, mainly sulphur oxides, nitrogen oxides and carbon dioxide.

Keywords: green innovation in shipping, green shipping, environmental regulations in shipping, shipping and the environment.

1. General Introduction

1.1. The International Shipping at a Glance

The maritime transport is the backbone of international trade and globalisation. At the beginning of 2017 the world merchant fleet consisted of about 93.000 ships of a total capacity of 1.86 billion DWT. (UNCTAD, 2017) All these ships served world seaborne trade, which volumes surpassed, for the first time in history, 10 billion tonnes in 2015. Since 1980 the international seaborne trade has almost trebled (from 3.704 millions of tons to more than 10.287 millions of tons in 2016). Although the pace of recent developments in maritime trade is not as dynamic as in the previous years (as it reflects the slowdown in world economy and weaker GDP growth), seaborne trade accounted for over 80% of total merchandise trade in terms of volume. In value terms the share was estimated at about 70 % (UNCTAD, 2017).

1.2. The Impact of Air Emissions From Shipping on Humans and the Environment

Shipping is the most environmentally friendly mode of transport when we refer to the emissions per one tonne-kilometre. Nevertheless, it exerts a huge impact on the environment and is the source of negative externalities.
Shipping generates pollutions of different kinds. These include a range of air pollutants such as Sulphur oxides (SOx), Nitrogen oxides (NOx), particulate matters (PM), volatile organic compounds (VOC), greenhouse gases (GHG), and black carbon (BC), as well as sewage, ballast water, underwater noise, just to mention those which have attracted a special attention in recent years.
The primary source of air pollution is the process of fossil fuel combustion. According to various estimations ships generate approximately 5–12% of all SO_2 and 10–15% of the global anthropogenic NOx emissions from fuels (Eyring et al., 2005; Merk 2014). The reason for this quite considerable share is that shipping still uses the fuel of a quality that is no longer available and allowed in other transport modes. The share of shipping sector in global CO_2 emissions from the combustion of fossil fuels is not so spectacular, estimated at 3.1 %; however, it is projected to increase by 50% to 250% until 2050 if no additional policy instruments are implemented (IMO, 2013).
There is a lot of evidence of considerable negative impact of air emission on human health and life as well as on the environment. Sulphur dioxide and nitrogen oxides emitted into the atmosphere may react with water, oxygen and other chemical molecules and form, among others, acids and particulate matters, as well as contribute to the formation of ground level ozone. These pollutions have a strong influence on human life and health and may cause different serious health problems, including asthma, lung cancer, cardiovascular and pulmonary diseases or heart attacks, just to name a few. Corbett et al. (2007) have estimated that because the vast majority (70%) of these emissions occur within 400 km of coastal communities, around 60,000 premature deaths each year are attributed to shipping emissions, mainly in the seaside areas of East Asia, South Asia and Europe. They are also very harmful to the natural environment, contribute to seas eutrophication, affect sensitive vegetation and ecosystems, as well as have a climate-forcing impact.
All these external negative effects translate into costs (e.g. costs of illness, hospitals' admissions, premature death, degradation of environment, loss of productivity etc.), which lead to market failure. The proper response to such a phenomenon is internalization of external costs, thus various environmental policy instruments have been developed to address this complex issue.

2. Instruments of Environmental Policy and Their Impact on Innovations

Market forces alone would not encourage companies to improve their eco-performance and would not lead to the development of green technologies, thus public intervention in the form of environmental policy instruments is crucial. Governments have a wide array of policy instruments at their disposal to combat pollution and incentivise innovations (Barde 1995; OECD, 2010; Mgiler and Vincent, 2013):

- Regulatory instruments ("command and control"), the most prevalent of which are technology- and performance-based standards; they allow relatively little flexibility with regard to the measures enabling achieving goals. (Barde, 1995; Mgiler and Vincent, 2013)
- Market-based (economic) instruments, that encourage behaviour through market signals rather than through explicit directives regarding pollution control levels or methods (Mgiler and Vincent, 2013); these include taxes, charges and tradable permits; in comparison with regulatory instruments they are considered to better address the problem of pollution by encouraging lower cost abatement across polluters (OECD, 2010).
- Subsidies, which can, under certain conditions, stimulate innovations, when we define them as "financial aid for research, development and investments in clean technology" (Georg *et al.,* 1992).
- Voluntary agreements and informative instruments (e.g. awareness raising, knowledge transfer, best practices).

Regulatory instruments are treated by the neoclassical economics as a burden for companies, but necessary for the society. However, they can also be perceived as means for improvement of companies' performance by accelerating the innovation-driven activities. This relationship between environmental regulation and economic performance is commonly known as the Porter hypothesis. The Porter hypothesis (Porter and van der Linde, 1995) stands that environmental regulations (market-based instruments in particular) can "trigger innovation that may partially or more than fully offset the costs of complying with them". Environmental regulations are therefore promoted as a "win-win" strategy, leading to better environmental quality and better economic performance and competitiveness of companies.

There are many studies attempting at investigating this hypothesis (e.g. Ambec *et al.,* 2013; Rubaschkina *et al.,* 2015); however, they bring ambiguous results. Dechezlepretre and Sato (2014) states that there is plenty evidence that environmental regulations foster innovation in clean technologies and discourage R&D in polluting technologies. Generally, most of the literature confirms the positive relationship between the number of green patents and environmental regulation, so called weak Porter hypothesis (Rubashkina et al., 2015 refers to many of them). On the other hand, Jaffe and Palmer (1997) in their study did not find a statistically significant link between regulatory compliance expenditures and patenting activity. Nevertheless, they discovered a significant positive correlation between pollution control expenditures and R&D undertaken by the regulated industry, although the scale of this effect was small. These findings were not confirmed by the study of Rubashkina et al. (2015), in which the manufacturing sectors of 17 European countries between 1997 and 2009 were analysed. The authors revealed that environmental regulation leads to an increase in patent applications but has no impact on R&D expenditures. Furthermore, they have a negligible influence on companies' productivity, despite the undertaken abatement measures and environmental control, what means that the win-win situation (also called the strong Porter hypothesis) has not been proven. The positive influence of environmental regulations on companies' innovations was also confirmed in recent studies from China (Zao and Sun, 2016), in which authors investigated Chinese pollution-intensive corporations panel data samples during 2007–2012. However, they also disclosed negative, although insignificant, effect of environmental regulatory measures on competitiveness. Ramanathan et al. (2017), after conducting nine case studies among UK and Chinese companies, argued that those, which choose a proactive approach towards the requirements imposed by environmental regulations and adapt innovatively, are "better able to reap the private benefits of sustainability".

The discrepancies between research outcomes may be attributable to the way in which the regulatory instruments are designed and if they are appropriately tailored to the particular problem that needs to be tackled. Some authors claim that regulations should be "innovation friendly" i.e. they should give the flexibility with regard to measures undertaken and specify only the desire outcome (Majumdar and Marcus, 2001). The same feature of regulatory measures is also emphasized in more recent studies (e.g. Ramanathan *et al.,* 2017). There are also other factors determining the involvement of the company in innovative solutions that should not be overlooked. These include: a firm's resources and capabilities (Ramanathan et al., 2017); managerial attitude and perception (Lopez-Gamero, 2010); business environment and market vulnerability; company size, its competitive position and financial stability; profile of business (sector); model of ownership.

3. Recent Environmental Regulations in Shipping

Increasing concerns over the impact of shipping air pollution on people and the environment have encouraged policy makers to deal with this complex issue. So far no internationally recognized market based instruments have been introduced with regard to shipping air emissions. However, a wide range of regulatory instruments aiming at the reduction of the negative external effects from shipping as well as associated external costs have been developed both on the international and regional levels. The leading role in the development of global regulations aiming at minimizing the negative impact of shipping belongs to the International Maritime Organization. Its flagship MARPOL 73/78 Convention supported by six annexes governing different aspects of shipping pollution, e.g. air emissions, sewage,

garbage or oils and oily water. Apart from the IMO, other organization such as HELCOM), OSPAR or the European Commission have also introduced their own regulations but on a regional scale.
A wide range of regulatory measures that address air emissions from ships, SOx and NOx in particular, have been adopted in recent years. They are governed by the Annex VI of MARPOL (entered into force in 2005) and its revised version with significantly tightened emissions limits adopted in 2008 (entered into force in 2010). Moreover, they introduced emission control areas for SOx (SECA) and NOx (NECA) with more stringent control of the emission of these gases (e.g. the Baltic Sea and the North Sea). These regulations are performance-based standards setting the particular level of emissions that needs to be achieved, which differ among different regions in the world.

3.1. Sulphur Dioxide

There are currently three standards of Sulphur emission on international seas (Tab. 1): 0.1% S m/m, 1.5% S m/m and 3.5% S m/m. However, the whole shipping industry will soon face a remarkable challenge as the global cap of 0.5% limit for Sulphur emission from ships will come into force in 2020.

Table 1
Limits for Sulphur emissions from the international shipping

Outside SECA	Inside SECA	EU special requirements
4.5% m/m/ prior to 1 January 2012	1.5% m/m prior to 1 January 2010	0.1% m/m vessel in berth in all EU ports from 1 January 2010
3.5% m/m on or after 1 January 2012	1.00% m/m on or after 1 January 2010	Inland waterways - max 0.1% S from 1 January 2010
0.5% m/m on or after 1 January 2020	0.1% on or after 1 January 2015	1.5% m/m for passenger ships operating on regular basis outside SECAs

Source: own elaboration

The regulation contains also the elements of technological based standards, as it refers to different technologies that may be used to meet these requirements. However, ship-owners still have a flexibility with regard to the measures intended to achieve the desired outcome. Therefore, instead of switching to low sulphur fuels, which price is considerably higher than that of conventional fuels, the regulation allows shipowners to utilize other compliance methods:

- using alternative fuel types such as LNG, methanol etc.;
- operating on high sulphur fuel oil after installation of exhaust gas cleaning systems (EGCS) on the ship board; this system must be designed according to the guidelines and approved by the IMO and ensure that the sulphur content in the exhaust is 6.0 g SOx/kWh or less;
- utilising any other technological method that is verifiable and enforceable to limit SOx emissions to the appropriate level; these methods should be also approved by the IMO.

3.2. NOx Emissions

NO_x emissions are addressed by the MARPOL Convention and its Annex VI, in Regulation 13, that provides for the control of NO_x emissions from marine diesel engines of over 130 kW output power (excluding ships used solely for emergency purposes). Different levels (tiers) of control apply based on, for example, the ship's construction date. Within each tier the engine's rated speed determines the actual limit. (Tab. 2) NO_x Tier III applies only to specified ships operating in areas designated as Emission Control Areas (e.g. the Baltic Sea and the North Sea). Tier I and Tier II limits apply globally regardless of ECAs for NO_x being established or not.

Table2
MARPOL 73/78, Annex VI NOx Emission Limits

Tier	Total weighted cycle NOx emission limit [g/kWh]			Ship construction date on or after
	n<130	130≤n<2000	n≥2000	
I	17	$45 * n^{(-0.2)}$	9.8	1 January 2000
II	14,4	$44 *n^{(-0.23)}$	7.7	1 January 2011
III	3,4	$9*n^{(-0.2)}$	2.0	1 January 2016 or later

n- engine's rated speed (rpm)
Source: MARPOL 73/78, Annex VI.

3.3. CO_2 Emissions

CO_2 emissions from shipping due to problems with allocating the ownership of these emission, have not been included in the international climate agreements (e.g. Kyoto Protocol, the Paris Agreement). Therefore, the global approach to CO_2 reduction falls to the IMO, which has developed a set of mandatory measures to reduce GHG emissions from shipping. In 2011 the "Regulations on energy efficiency for ships" was adopted as the new chapter to Annex VI of MARPOL. This annex introduced, among others, obligatory technical and operational measures such as the Energy Efficiency Design Index (EEDI), which sets compulsory energy efficiency standards for new ships. They aim at enhancing ships' efficiency and require that all ships constructed from 2025 must be at least 30% more efficient compared to those from the reference line (the average efficiency of ships built between 1999-2009).
In April 2018, the IMO adopted an „Initial IMO Strategy on reduction of GHG emissions from ships", being a milestone in the process of combating GHG emissions. The Strategy outlines a target to reduce GHG emissions by at least 50% by 2050 compared to 2008, with the overall aim of phasing them out (IMO, 2018). Moreover, the IMO has introduced Data Collection System, starting on 1 January 2019, which will oblige ship-owners to monitor and report data concerning fuel consumption and CO_2 emissions. It will be the parallel monitoring regime to that created at the EU level, i.e. EU MRV regulation (Monitoring, Reporting and Verification), which has already commenced at the beginning of 2018. The main purpose of those systems is to gather information needed for further discussion on emission targets and reduction measures, including market-based instruments.

4. Innovations in Shipping as a Response to Environmental Regulations on Air Emissions

It is quite challenging for ship-operators to conform to the strict environmental regulations, while remaining profitable at the same time. However, these environmental regulations affect not only ship-owners, but the whole shipping industry, including shipbuilders, manufactures of ship components (e.g. engines), seaports, ship fuel providers, etc. There have been and still are many worries that they will place an excessive burden on the industry and cause a distortion to the market and competitiveness. On the other hand, they may offer a chance to escape from "a polluting economic trajectory and move to a 'clean' one" (Dechezlepretre and Sato, 2014) and serve as a trigger for innovations, as there are still a lot of inefficiencies in shipping and thereby areas for improvements.
Consequently, companies involved in shipping are now diverting considerable resources to the search for viable solutions. Indeed, we can observe a surge of activity in R&D, resulting in an array of innovative solutions aiming at reducing the air emission from ships that have started to penetrate the market. Some R&D activities are undertaken by the private sector with their own funds, some are collaborative R&D programmes among shipping industry, governments, institutions, and research entities, financed by various sources (e.g. the EU funds under HORIZON 2020 programme). Particularly active in R&D and dissemination of its results are engine manufacturers, for example Rolls-Royce (UK), Wärtsilä (Finland), Mitsubishi Marine Engines (Japan), MAN and MTU (Germany), Caterpillar and Cummins (US), and shipbuilding companies, mainly from Asia (e.g. Hyundai Heavy Industries and Samsung Heavy Industries (Korea), Mitsubishi Heavy Industries and Kawasaki Heavy Industries (Japan), COSCO Shipyard Group (China)). The demand for new green innovative technologies and solutions becomes even more crucial now in the light of the introduction of a new, global cap for SOx emission from shipping in 2020 (i.e. 0.5% S in mass) as well as the ambitious CO_2 emission reduction target. Therefore, it is not surprising that R&D efforts are intensified and innovation is stimulated, in three areas in particular:

- exhaust gas cleaning systems,
- alternative fuels and new energy sources,
- energy efficient merchant vessels.

4.1. Exhaust Gas Cleaning Systems

Exhaust gas cleaning system (EGCS, commonly known as scrubber) is the technology in which ship-owners have invested to comply with SECA limits. It allows removal of sulphur oxides from ship's engine and boiler exhaust gases without switching to the considerably more expensive low-sulphur fuels. (Fig. 1)
Currently there are two main types of sulphur scrubbers: dry and wet, although the use of dry scrubbers is marginal (only one ship equipped with this solution). Moreover, dry scrubber's technology can not be considered innovative as it is already widely used in land-based industries. The most popular and innovative in the shipping industry are wet scrubbers: open loop scrubbers, closed loop scrubbers, and hybrid scrubbers having the flexibility to operate in both open and closed loop (Klopott, 2015). In *open loop scrubbers*, seawater is pumped from the sea through the EGCS, cleaned and then discharged back to the sea and the washwater is not recirculated (Lloyd's Register, 2012), whereas in c*losed loop scrubbers* the fresh or sea water that is chemically treated (usually by caustic soda injection) is used to effect exhaust cleaning. Most of the scrubbing agent is re-circulated with only minimal water intake and effluent discharge (Bureau Veritas, n.d, Wärtsila, 2017).
Despite some limitations (technological, operational, safety-related) of the scrubber technology, it is spreading throughout the industry and an increasing number of ships (mainly ro-ro and ferries) are now equipped with this kind of EGCSs. Their number is systematically increasing. For example, in the North and the Baltic Seas in 2000 there was only a single scrubber-equipped ship in operation, whereas at the beginning of 2017 nearly 100. Worldwide, the number

of vessels fitted with scrubber has reached 240 as of December 2017 (Springer, 2017). Reflecting latest IMO decision to lower the cap to 0.5% sulphur content from 2020, according to some scrubber manufacturers (e.g. DuPont Clean Technologies) up to 25% of global fleet will be fitted with this abatement technology by 2025 (Seatrade, 2016).

4.2. Alternative Fuels and Energy Sources for Ships

In the case when ship-owners do not prefer to operate the vessel using the more expensive low sulphur fuel or are reluctant to scrubbers, they may choose the alternative fuel path. Searching for viable alternative energy sources would not only satisfy the growing environmental demands but may also foster more efficient operation of ships. The most promising fuels such as LNG, biofuel, methanol as well as hydrogen, have already been widely researched and tested.

The innovative technology of utilizing LNG as a ship's fuel, pioneered by Norway, attracts special attention of the shipping industry both for economic (the price of LNG is much lower that of traditional fuels) and environmental reasons (considerable reduction of air emissions). This technology is powered by numerous innovative solutions (adopted by both ships and land-based facilities), ranging from the construction of LNG storage tanks and engines to the LNG bunkering facilities. Moreover, some obstacles to the use of LNG related to international legislation have already been overcome, making it all the more attractive and viable alternative, resulting in an increasing number of LNG-fuelled ships. At the beginning of May 2018 there were 121 LNG-fuelled ships in operation (17 % growth over the past 12 month) and the next 132 have been ordered (36% growth) (Corkhill, 2018). The latter includes nine LNG-powered containerships of 22,000 TEU capacity, ordered by one of the biggest container line, CMA CGM Group; the first is expected to be delivered in January 2020 (Hand, 2018).

The use of methanol as as an alternative fuel is also receiving increased attention. So far, there are seven methanol-fuelled ocean-going vessels of about 50,000 DWT, and in 2019 another four vessel of similar capacity will join this group. All of them are (will be) equipped with very innovative MAN B&W ME-LGI 2-stroke dual fuel engines that can run on methanol, fuel oil, marine diesel oil or gas oil (Methanex, n.d.). Another example of the use of methanol in shipping is the world's first methanol powered ferry *Stena Germanica*, launched in 2015 and operated by Stena Line. (Ship2Shore, 2015)

Yet another promising innovative and alternative fuel that could play a role in the future is hydrogen, particularly for use in fuel cells technology. Fuel cells convert chemical energy of hydrogen into electricity and can be used as auxiliary power or as supplementary propulsion power in hybrid ships (DNV, 2014). Fuel cells for maritime use are more commercially available now and some ship-owners (e.g. Royal Caribbean) intend to invest in this technology. (Royal Caribbean Cruises, 2016)

In addition to fuel cell systems, battery systems and wind-assisted propulsion are also considered and tested. Although speaking of wind powered ships in the context of innovations may be surprising, various sail arrangements, fixed wings and Flettner rotors have been already developed and tried on merchant vessels. One the concepts put forward is the B9 ship with a sail-based propulsion that aims to deliver 60% of ship's power, the rest coming from biofuels (B9 Energy Group, 2015).

Another technology that utilizes wind energy is the Flettner rotor (Fig. 2) – vertical cylinders which spin and develop lift due to the Magnus effect as the wind blows across them. Depending on vessel characteristic and voyage conditions, it enables to cut the main engine fuel consumption by 3% - 15% (GLoMEEP, n.d.) Recently (April 2018) Viking Line has put into operation the LNG-fuelled ferry *Viking Grace* with an installed rotor sail, making it the first passenger ship in the world equipped with a rotor for wind-assisted propulsion. The project has received funding from the EU's Horizon 2020 research and innovation programme. (Norsepower, 2018)

Even higher reduction potential has the SkySail technology (Fig. 2), combining expertise of cofounders (SkySails, DSM Dyneema and Gleistein) in kite technology, synthetic fibres and rope construction. (SkySail, n.d.) The ship's regular propulsion is aided by towing kites, which, depending on the prevailing wind condition, can result in reduction of ship's emission by 10-35 %. (DSM, 2011)

As far as battery powered propulsion systems are concerned, this is a technology already available for small ships, but cannot power large, deep-sea vessels and so far cannot be treated as a substitution for fuel. (DNV, 2014)

Fig. 2.
Flettner rotor on a board of ferry "Viking Grace" and SkySail
Source: Norsepower (2018) and SkySail (n.d.)

4.3. Energy Efficient Merchant Ships

A wide array of technological innovations is available to enhance energy efficiency of ships and thereby meet the regulatory requirements with regard to air emission as well as EEDI. These technologies mainly concern ship design, propulsion and machinery. As far as ship design is concerned innovative modifications of hull shape that minimize the hull resistance are of particular importance. For example, the resistance between the water and the hull can be reduced by introducing a layer of air bubbles under the hull (air lubrication/air cushion) (Wärtsilä, 2009 and 2016). Modification to the aft-body of a ship (e.g. ducktail waterline extension) additionally combined with interceptor planes (that are fitted vertically to the transom of a ship) also have a positive effect on the resistance of the ship as they create a kind of lift effect. Moreover, lighter and stronger materials can be used to reduce ship weight and thereby fuel consumption and emissions.
Various innovation with regard to ship's propulsion are also available or tested. The propeller blade design as well as optimization of propeller-hull interaction may improve considerably the performance of a ship. For example, an innovative contra-rotating propeller, replacing the end-plated propeller and rudder bulb, has one of the highest efficiencies. (Wärtsilä, 2009 and 2016; DNV, 2013)
In the area of ship's machinery there are also many innovations, especially in the main and auxiliary engines construction as well as in energy recovery and storage on a ship board. Hybrid auxiliary power system is a good example of innovation of that kind. It consists of a fuel cell, diesel generating set and batteries, which can storage the energy surplus. In order to achieve maximum efficiency, the loading of each component is managed by an intelligent control system. The very promising in terms of energy management on the ship board is the waste heat recovery system, that enables to recover the thermal energy from the exhaust gas and turned it into electric power. It can provide up to 15% of the engine power. (Wärtsilä, 2009 and 2016; DNV, 2013)
Taking into account possible innovative solutions, which can be combined together to enhance ship energy efficiency, several green ship ideas, sometimes futuristic, have been already developed. One of the extraordinary concept of zero-emission ship called Eco-ship 2030 was designed by NYK – one of leading ship operators (Fig. 3) Although it has not been put into practice yet, it employs some distinctive, innovative solutions enabling the reduction of CO_2 emission by 69%, such as weight reducing ship structure, optimized hull form, solar and wind energy harvesting as well as fuel cells to power the ship. (NYK Group, 2017)

5. Conclusion

Following the green activities that are undertaken now by the shipping industry, the vast majority of innovations sprout from regulatory instruments of environmental policy. The IMO regulations are an example of well-designed instruments of that kind, which could more than offset the additional regulatory costs. Although they are not as flexible as market-based measures, they allow ship-owners to choose a technology pathway which suits their needs and capabilities. There are many prerogatives and real evidence from the shipping industry that they consequently may contribute to increasing efficiency and competitiveness in the long-term, leading in the future to emission neutral shipping.

Nevertheless, it should not be neglected that companies involved in the shipping sector have different capacities to deal with the challenges posed by eco regulation. There is a need for adequate financial and technical resources and support to meet the new requirements; sometimes a wide-scale collaboration is crucial, sometimes the state aid as well.

IBERIAN MOTORWAYS OF THE SEA. AN OVERVIEW AFTER 15 YEARS OF VAN MIERT REPORT

Francesc Xavier Martínez de Osés[1], Marcel·la Castells i Sanabra[2]
[1,2] Department of Nautical Science and Engineering, Universitat Politècnica de Catalunya – BarcelonaTech, Spain

Abstract: After 15 years of the Van Miert report proposing to include the Motorways of the Sea in the TEN-T schema, an overview wants to be done in the Iberian Peninsula scenario. In 2015 the Intra European trade (Eurostat, 2017) supposed around 11,263.4 millions of tons, being through Short Sea Shipping (SSS) up to 1.808,5 millions of tons and only the 13.6 % on Ro/Ro trades (246.04 millions of tons or the 2.2 % over the total volumes). In the case of Spanish Short Sea Shipping traffics raised to 196.668 millions of tons (234.7 millions of tons in 2016 from www.spc-spain.es) being only 15.33 millions of tonnes or 7.8 % under Ro/Ro schema. Keeping in mind these figures, it is asked which rate of success should be acquired with the maritime transport promotion policies in European Union. The proposed paper wants to analyse in deep, which reasons could explain the low volumes that still Intra European Short Sea Shipping gets. The analysis will begin with a review of the SSS and Motor Ways of the Sea official definition and after having a complete overview of traffic figures, to propose a model to analyse the best mode to connect different Iberian destinations offered to Consignors, in an attempt to transfer part of the cargo from road to sea option.

Keywords: motor ways of the sea, short sea shipping, Western Mediterranean.

1. Introduction

Motorways of the Sea (MoS) concept was officially mentioned for first time in the White Paper of Transport (EC, 2001) with the main objective to reduce the existing and future bottlenecks in Trans European transport Networks (TEN-T) and additionally to improve the logistic integration of short sea shipping (ANAVE, 2004). From the beginning there was the thought that the building of links under 500 km. of distance, would require initial support to be developed like a quality stamp or distinctive or specifically financial aid from European funds like (in fact has been) FEDER or Marco Polo programs inter alia.

Coming back, among first initiatives to shift road transport to the sea representing the concept of MoS, was the action known as *Autostrade del Mare* carried out by Viamare S.p.A. in 1992 (Beškovnik, 2013). Further attempts to draw a definition or operational frame to the MoS concept are identified from the year 2002 (Ministry of Transport of Finland 2002, Gijón declaration 2002, Van Miert report 2003). A tentative definition suggested them as any multimodal service that includes a maritime leg with minima standards of quality that elevates them over the general concept of services understood as Short Sea Shipping (ANAVE 2004) that supposed a real alternative to road transport and contributed to the reduction of congestion, the environment conservation and the economic growth.

From an academic point of view, different proposals of definition were provided (Baird, 2007; Paixão, 2008). However, some authors were of the opinion that never has given a precise definition of a MoS (nor SSS) (Douet & Capuccilli, 2011). MoS can be deducted that are door to door regular services, serving with high frequency, including a short sea leg allowing a significant modal shift. Also they are called floating infrastructures, that move goods by sea from one member to another and aims to substitute land motorways to avoid congestion and give access to countries separated from the mainland and enable better integration of waterborne with surface, modes. (Paixao 2008). From these last definitions it seems that MoS should be limited to short sea services using Ro/Ro ships among member states so few potential for modal shift seems to be as most of them are operating in captive markets.

More recent information from EU web site established as main objectives of MoS, the concentration of freight flows on sea based logistical routes to improve existing or new maritime links being viable, regular and frequent to reduce road congestion and/or improve access to peripheral and island regions and States. So as to provide more efficient, commercially viable and sustainable alternatives to road-only transport.

Even that SSS traffics increased 12% between 2001 and 2010 (Ng 2013). However, SSS in general has not improved as expected because seems that its definition not fit with potential impact Ro/Ro services that are mostly captive and only a few remove trucks from roads. Additionally, shore infrastructures are subsidized, being the opposite scenario in maritime sector.

2. Spanish Scenario

During the year 2017, SSS services reached 248 millions of tons, supposing an increase of 6% from 2016, being split in 19% national coastwise and 81% of external traffics. But due to a reduction in the number of ships, the overall connections increased mainly when referred to SSS as alternative to road around 42% in the Atlantic basin and 25% in the Mediterranean one. The number of MoS in the Atlantic side was 2 and in the Mediterranean were 3. The mean occupation with respect to offer was 73.1% decreasing from 2016 when reached 80.1%, in both basins the offer increased and demand didn't follow this tendency being the overall figure of occupancy lower. From a global perspective the SSS share in the rolling traffic passed from 10% in 2014, to 9.7% in 2015 and to 9.1% in 2016 (SPC Spain 2018).

2.1. The Offer of MoS Lines in Spain

During the second semester of the year 2017, in the Atlantic basin operated 50 SSS services being up to 32 (64%) a real alternative to road, having 2 more than 3 calls per week and thus considered as MoS. During the same period in the Mediterranean up to 38 (28%) services were considered an alternative to road out of 135 lines and only 3 considered MoS (SPC Spain 2018).
As it has been mentioned before, the total number of MoS in Spain has been in 2017 of 5 lines operated by 2 shipping companies, linking 8 international ports and served by up to 12 ships. Considering the two basins, in the Atlantic case we find 2 shipping companies in 2 MoS with 4 Ro/Ro ships linking 2 ports. In the meanwhile, in the Mediterranean there were 3 MoS served by only 1 shipping company, linking 6 ports and using 8 Ro/Pax ships. Being the average frequencies of call of 3.1 and 5 times per week, respectively.

Table 2
Detail of motorways of the sea in the Mediterranean and Atlantic basin. Year 2017

Mediterranean MoS	Frequency	Atlantic MoS	Frequency
Barcelona Civitavecchia	Daily	Algeciras Vigo Saint Nazaire Le Havre	3 x week
Barcelona Livorno Barcelona Savona	4 x week Daily	Santander Le Havre	3 x week
Valencia Livorno Valencia Savona	Daily

2.1. Evolution of the SSS Traffics in Spain

In January 2004, Spanish government established in Algeciras a position in order to promote SSS services. In that year, the short sea services apart from feeder connections existing nowadays there were up to 24 services running.
During the year 2004, 12 companies were linking 8 Spanish ports with other European destinations (see Table 3).

Table 3
Detail of Spanish SSS services. Year 2004

Company	Frequency	Route	Type of ship
Med Seaways	2 x week	Tarragona and Savona	Ro/Ro
Cía. Trasatlántica Española	every 2 weeks	Valencia, Barcelona, Piraeus, Istanbul and Izmir	Containers
Cía. Trasmediterránea	2 per week	Vigo and Saint Nazaire	Ro/Ro
Geest North Sea Lina / Naviera del Odiel	weekly	Bilbao, Rotterdam and Tilbury	Containers
Grandi Navi Veloci	weekly	Barcelona and Genoa	Ro/Ro
Naviera Pinillos	weekly	Bilbao, Southampton, Felixstowe and Thamesport Bilbao, Dublin, Liverpool and Greemock	Containers
Transmed	2 x week	Tarragona, Genoa and Salerno	Containers
UECC	2 x week	Bilbao, Pasajes, Portbury Santander, Pasajes, Vlissingen, Sheerness and Zeebrugge Vigo, Le Havre, Zeebrugge, Sheerness and Bremerhaven	Ro/Ro
Xpress Container Lines	weekly	Vigo, Le Havre, Thamesport, Rotterdam and Vigo Barcelona, Genoa, Livorno and Fos Gijón, Rotterdam, Bilbao, Gijón Vigo, Leixoes, Rotterdam and Vigo	Containers

Company	Frequency	Route	Type of ship
Grimaldi Napoli	3 x week	Valencia, Livorno, Salerno, Tunis, Malta	Ro/Ro
	daily	Barcelona and Civitavecchia	
OPDR Hamburg	Every 2 weeks	Hamburg, Bremen, Antwerp, Le Havre, Felixstowe, Southampton, Rotterdam, Lisboa, Leixoes and Vigo	Containers
	weekly	Rotterdam, Bilbao and Le Havre	
Flota Suardíaz	weekly	Bilbao, Zeebrugge, Vlissingen, Southampton, Vlissingen, Zeebrugge and Santander. Gijón, Saint Nazaire, Southampton, Vigo and Setúbal. Setúbal, Vigo, Gijón and Vlissingen.	Ro/Ro
	2 per week	Tarragona and Livorno Tarragona, Civitavecchia and Salerno	

Source: Own based on SPC Spain web site http://www.shortsea.es (consultation date June 2018)

As it can be seen only two services in Mediterranean basin had 3 or more calls per week and then could be considered as MoS and the actual Atlantic services then had only two calls per week. Also during the year 2007, two new services were opened in each basin. One carried out between Bilbao and Zeebrugge with three sailings per week that definitely left the Spanish port in 2015. And a second service in the Mediterranean between Barcelona and Livorno, still in force.

3. Case Study

This section identifies main Spanish ports involved in Short Sea Shipping and proposes new Motorways of the Seas. Main Spanish cities are connected with the most important Spanish ports and, on the other hand, connected to most important European ports and cities. Up to 54165 links between Spain and European countries were studied, based on time and costs. Moreover, three different types of ships are considered, namely, conventional ships (23 knots); fast ships (23 to 30 knots) and High Speed Crafts. For time and cost calculation purposes representative ships are used (Table 4).

Table 4
Detail of main characteristics of the considered ships

Particulars	Conventional Eurocargo Istanbul	Fast ship Superfast Galicia	High Speed Craft Millenium 3
Length	195	160	96
Beam	25.2	23.2	26
Draught	7.8	6.8	3.3
Power (kW)	12510	34300	38501
Speed (knots)	20	23.2	42
Gross Tonnage (GT)	20775	14560	6360

Source: Own based on www.equasis.org. (consultation date june 2018)

Travelled distance and speed are factors closely related to engine consumption and then conditioned by the fuel costs. Capital costs, crew costs and RMIA (i.e. repairs, maintenance, insurance and administrative) costs are considered. These costs are limited to the navigation phase, considering only the ship in open seas. Port costs like taxes, fees, discharge operation or demurrages are not considered. The method used is based on Stopford (1997); however different authors have proposed alternative methods to calculate them (Anderson and Ivehammar, 2016; Tzannatos, 2005; Tzannatos *et al.,* 2014; Mulligan and Lombardo, 2006 or Martínez de Osés and Castells, 2009).
Capital costs dependent on an additional time unit at sea, are assessed based on Gross Tonnage (GT). The capital cost per day is based on the Compensated Gross Tonnage (CGT) factor. The formula used is taken from the Compensated Gross Ton (CGT) System, from OECD Directorate for Science Technology and Industry in its Council Working Party on Ship building (OECD 2007):

$$CGT = A \cdot GT^{B} \qquad (1)$$

Being the factors A and B obtained from OECD (2007). From equation (1) applied to the price of all ships, the daily capital cost is obtained considering a credit at an interest of 5% and a useful and repayment life of 25 years (Tzannatos *et al.,* 2014).

$$\text{Capital cost} = 14.014 \cdot GT0.63\ €/\text{day} \qquad (2)$$

Regarding the group of repairs, maintenance, insurance and administrative costs, Jansson & Shneerson (1987) suggest that this should be around 3.5% of the daily capital costs. General formula to calculate RMIA costs is shown below:

RMIA = 0.4905·GT0.63 €/day (3)

Crew cost, this unitary value is difficult to estimate due to the variability if passenger and non-passenger ships are considered. The resultant formula of the crew costs is given by:

Crew Costs = [2.1(Officers·Wage) + 1.5(Mates·Wage)/30]·Sailing time/24 (4)

Based on Anderson and Ivehammar (2016, 2017) and Larsson (2010), fuel consumption for a specific journey is calculated considering the hull resistance as:

$$C = \frac{R_T \cdot D}{E_{MGO} \cdot \eta_T} \tag{5}$$

Where
C fuel consumption, in kilogram (kg)
R_T vessel resistance, in kilo newton (kN)
D sailed distance (meters)
EMGO the specific energy of Marine Gas Oil, 42700 MJ/kg is considered
η_T thermal engine efficiency

The total resistance of the vessel is calculated by a model for hull resistance (Larson and Raven, 2010):

$$R_T = \frac{1}{2} \cdot \rho \cdot V_S^2 \cdot (B + 2 \cdot d) \cdot L \cdot C_B \cdot C_{TS} \tag{6}$$

Where
ρ water density, in kg/m3
Vs speed, in m/s
B beam, in m
d draught of ship, in m
L length of ship, in m
C_B block coefficient, 0.67 is used
C_{TS} resistance constant, 0.0022 is used

4. Results

The main objective of this contribution is preselect the Spanish ports susceptible to belong to a Motorway of the Sea and find suitable routes in the European framework. Figures 5 and 6 show the most viable routes in terms of time and cost, respectively.

Fig. 1.
SSS Suitable routes in terms of time
Source: Own based on internet caught picture

Fig. 2.
SSS Suitable routes in terms of cost
Source: Own based on internet caught picture

Finally, based on proposed model explained in the above section, table 5 shows the final suitable routes connecting different European destination (one of them is one Spanish port) considering time, cost and type of ship.

Table 5
Proposed routes in terms of time, cost and type of ship

Country	Route	Type of ship
Germany	Bilbao-Bremen	Fast
	Bilbao-Koln	Fast
	Pasajes-Bremen	Fast
Belgium	Bilbao-Antwerpen	Fast
	Pasajes-Antwerpen	Fast
Croatia	Valencia-Rijeka Bakar	Fast
Denmark	Bilbao-Esbjerg	Conventional
France	Bilbao-Rouen	Fast
Poland	Bilbao-Gdansk .	Fast
	Pasajes-Gdansk	Fast
Greece	Valencia-Igoumenitsa	Conventional
	Valencia-Thessaloniki	Conventional
The Netherlands	Bilbao- Nijmegen	Fast
	Bilbao-Den Helder	Conventional
	Pasajes-Nijmegen	Fast
	Pasajes-Den Helder	Fast
Italy	Valencia - Livorno	Conventional
	Valencia-La Spezia	Conventional

Source: Own based on detailed calculations

5. Conclusion

Final calculations have been carried out, considering different goals to be accomplished. Keeping in mind the results showed in the previous section, the first conclusion is that HSC ships due to the cost of consumption are skipped from the first assessment. The selection between fast or conventional Ro/Ro ships depends on the possible competence with only road transport chains. Time is a factor to be considered but for certain type of goods, frequency is another factor to be considered by final costumers and also reliability or consistency along the time or influence of the seasonality. It is

also considered that higher speeds supposes higher consumptions and then pollutant emissions; however there combinations of routes with faster speeds where time makes them competent against only road transport chains.
As a suggestion to shipping companies, and of course subjected to further checking we propose different short sea links that can be real alternatives to only road transport chains with different European countries. Existing MoS are not considered in the proposal as they are at least at this moment reliable and efficient transport alternatives. Some of them get the geographical advantage that some combinations have, like is the case among Italy and Spain. Some others are relying in an advantage on only time or cost and a few on both; but they are.
As a concluding idea, it is left still a proper definition of SSS and MoS for exactly define them and make a clear frame of what are the links susceptible to get consideration and funding from EU.

EFFECT OF MULTICULTURAL AWARENESS AND COMMUNICATION ON SAFETY ONBOARD A VESSEL

Nermin Hasanspahić[1], Srđan Vujičić[2], Darijo Mišković[3]
[1,2,3] *University of Dubrovnik, Maritime Department, Croatia*

Abstract: The need for people to be able to talk to each other without prejudice comes with globalization. Maritime safety is largely dependant on adequate communication and mutual understanding of persons onboard vessels. Although maritime technology evolved, there is still a large number of maritime accidents. Inadequate communication and misunderstandings are one of the factors that can lead to human error, that in return can cause accident. Human relations onboard are also dependant on communication, especially in cases of multicultural crews. In order to understand each other and create safe working and living environment, adequate communication is essential. But, adequate communication is not always sufficient to overcome cultural differences between cewmembers. Answer to that issue could be multicultural training for all crewmembers on board vessels. Questionnaire with title: ″Multicultural awareness and communication on board a vessel″ was given to experienced seamen in order to uncover their opinion on adequacy of communication and human relations on vessels with multicultural crews.

Keywords: multicultural, communication, human relations.

1. Introduction

Maritime safety is still largely affected by human factor, since about 80% of maritime accidents are caused by human error (Hanzu-Pazara *et al.,* 2014). Inadequate communication and poor human relations in certain conditions are recognized as contributing factors to human error. In order to reduce human error and improve maritime safety, adequate communication and human relations needs to be implemented on board ships. International Maritime Organization (IMO) addressed that problem and implemented IMO Model Courses. English is internationally accepted as language that is to be used for emergency situations, and as such, good knowledge of English is essential in order to safely complete voyage between two ports. But, accidents due to inadequate communication between crewmembers, or lack of same still happen. Maritime industry must find solution and reduce such accidents to minimum. Seafarers should have adequate education and trainings ashore, what should be supplemented with trainings on board ships. Many shipping companies are doing their best in order to get best possible education and trainings for their employees, but there are some companies that are focused on profit and don't look into safety. A sound knowledge of English is precondition for making a good career at sea, what is commonly known by seafarers around the world.

Ships' crews are nowadays made of persons from different countires and continents, and as such there are many differences between them. As per Trenkner and Cole (2003) 80% of the world’s merchant ships have become multilingual and multiethnic in crew composition. One in ten ships operates with crews composed of five or more nationalities (Badawi and Halawa, 2003). Seafarers should learn cultural differences in order to understand and appreciate each other more. Multiculturality courses are improving teamwork on board ships and increase safety performance. Again, sound knowledge of English is essential for that.

2. Importance of Adequate Communication in Maritime Industry

One of the essential elements for strong organization is consistent and direct communication because it leads to trust between all parties (Vredenburgh, 2002). Communication can be divided into two categories, communication on safety issues and clear two-way communication. Communication on safety issues is considered as integral part of Safety Culture, and it comes in various forms, like policies and procedures, incidents reports, performance statistics and workplace inductions (Vecchio-Sadus, 2007). Safety communication in organization is achieved by two methods, internal and external communication. Internal communication includes different types of presentation for all staff and management, team meetings, notice boards, e-mails or even videos. Delivering annual reports, publications or telephone enquiries are usual methods for external communication (Vecchio-Sadus & Griffiths, 2004).

Researches in the past showed that poor communication was main reason for low safety performance to low productivity and morale (Hofmann &Morgeson, 1999; Alexander *et al.,* 1989, Michael *et al.,* 2006). According to Vredenburgh (2002), regular and direct communication should be promoted to increase safety performance.

In constructive and open communication atmosphere all team members would freely discuss problems, ranging from routine to non-routine issues, and jointly engage in problem solving (Fairhurst, 1993; Hoffman *et al.,* 2003).Those members who have high collective orientation are more likely to have increased attention to task and are willing to help other team members during task performance. Therefore, this attribute will facilitate process of coordination and communication inside the team (Salas *et al.,* 2008).

In recent years shipping industry has experienced a numerous incidents and accidents caused by human factor, explained by three elements: ergonometric constraints, human fatigue and inter-relation between people, i.e. their communication skills (Horck, 2010; 2006).

[1] Corresponding author: nhasanspahic@gmail.com

In order to fulfill crewing requirements and cut labor costs shipping companies usually employ multinational crews. A study carried by Seafarers International Research Centre, which included 10, 958 ships, shows that only one third of the ships have single nationality crews (Kahveci & Sampson, 2001; Hetherington *et al.,* 2006).
Presence of multinational crew implies a different language and culture background which is transmitted to the ship's complement. In cases when communication fails damages to property, environment, or loss of lives is possible.
According to Horck (2010) people from the same culture have to be able to communicate and language is basic facilitator of communication. In maritime industry English is standard language and proper knowledge leads to accident avoidance. Besides difficulties mastering a common language, misunderstanding and lack of communication has also been reported as common problem on ships (Hetherington *et al.,* 2006).
While the ship is in open waters navigation is usually performed by certified deck officer who is working alone on the navigational bridge. In cases when the ship encounters areas with congested traffic, when maneuverability is restricted, or ship is about to enter or leave port, navigation is carried out by a bridge team which work together. Also, in most ports of the world pilotage is compulsory and is common for a pilot to work together with ship bridge team, giving advices for actions to be performed during navigation and mooring operations. In all cases effective communication in common language is essential.
Some part of communication is so called non-verbal communication (Horck, 2010). Non-verbal communication can be explained as actions people do not say because they expect to be understood from manners and facial expression of other people. Culture constraints have an impact in understanding non-verbal communication (Storgard *et al.,* 2013).
Accident reports caused by communication failures are numerous. Horck (2006) presented accidents caused by lack of language constraints: the collision between Fu *Shan Hai* and *Gdynia* in 2004, collision between ships *Tricolor* and *Karibian* 2003, and the collision of *Silja Opera* in 2003. Besides accidents caused by language constraints, cultural constraints caused grounding of *Domiat* in 2004, and explosion on *Bow Mariner* in 2004.
Pyne and Koester (2005) summarized those related to different language, between bridge team and the pilot, crew and passengers, and those related to external communication and VHF communication with other ships. According to them, accident could be avoided with proper knowledge of English language. Besides language barriers, cases of misunderstanding where reported between crewmembers who speak same language. They summarized with the conclusion that adding people using English as second language and cultural differences between them, in the bridge team, can increase risk of miscommunication.

3. Multiculturality in Working Environment on Board Ships

The basic skill for surviving in a multicultural world, as has been argued, is understanding first one's own cultural values and next the cultural values of the others with whom one has to cooperate (Hofstede, 1997).
Language and culture is challenge in many maritime operations. Even persons who speak the same language can have a misunderstanding (Adams, 2010). Adequate communication is essential skill during maritime operations, especially in the crisis and crowd management, where team members should quickly understood each other. Different social groups or team members with different cultures may respond in own ways to similar situations (Maritime and Coastguard Agency, 2014). Ethnocentrism and prejudices about other cultures in maritime operations can make poor comunication among team members and can leed in catastrophic situation.
Everyone should understand that it does not matter from where you are coming or what cultural, ethnic or religious background you have, experienced or with no experience, there are, at all times, the possibilities to be successful. Dangerous tunnel vision could be always present for anyone and there is always possibility to change decision considering you have the right attitude and understanding of the value of a certain improvement. Understanding fellow crewmembers (knowing that people from different countires can behave differently) will lead to a positive outcome (Horck, 2004).
The communication is succesfull when the information is exchanged by all team members or everyone concerned with, it doesn't matter wich culture background team members belong. Accurate, clear and accepted communication leads to success. Anything less is failed communication and will lead to trouble (Adams, 2010).
According to UK Maritime and Coastguard Agency (2010), the work place is influenced by two different sets of cultural issues, related to differences due to a person's cultural background and organizational culture. Cultural differences increase the likelihood of different interpretations of the same event. A person's ethnicity may also make them more or less sensitive to the demands of the second set of cultural issues – the organizational culture in which the decision makers are embedded.
In order to reduce maritime accidents caused by human error, International Maritime Organization (IMO) implemented model courses, which are "*meant to suggest and help professors, lecturers and instructors in their teaching*" (Horck, 2003).
Among many learning objectives of IMO Model Courses 1.22, 2.07 and 1.39, particular attention is pointed on Cultural Awareness and Communication. As per training objectives the trainees should be able to explain the need of cultural awareness (sensitivity of cultural differences, methods for dealing with cultural differences, cross-cultural communication and effective communication on board and ashore) in duration of no more than one hour (IMO, 2002a, IMO, 2002b, IMO, 2014). After implementation of 2010 Manila Amendments as a part of additional requirement for Certificate of Competence (CoC) certification those courses are obligatory for all ship leaders (deck and engine

officers). But, just attending IMO model courses for officers is not precondition for safe working environment on board a ship.

4. Analysis of Present Situation in Maritime Industry

Authors conducted a survey in order to determine present situation regarding communications and multiculturality in maritime industry with title: "*Multicultural awareness and communication on board a vessel*". Tool for the above mentioned survey was questionnaire based on literature review and authors' expertise. Survey involved 70 seafarers of different nationalities and ranks. For all seafarers which had direct online access questionnaire was available online. For those which did not have that opportunity it was available in paper form.
Authors tried to poll seafarers of different nationalities and ranks in order to get perception about multiculturality and communication on board ships.
Nationalities of seafarers involved in questionnaire were: Croatian (59%), Filipino (16%), Indonesian (16%), Ukrainian (4%), Russian (3%), Indian (1%) and Montenegrin (1%).
Seafarers of all ranks were polled (Figure 1).

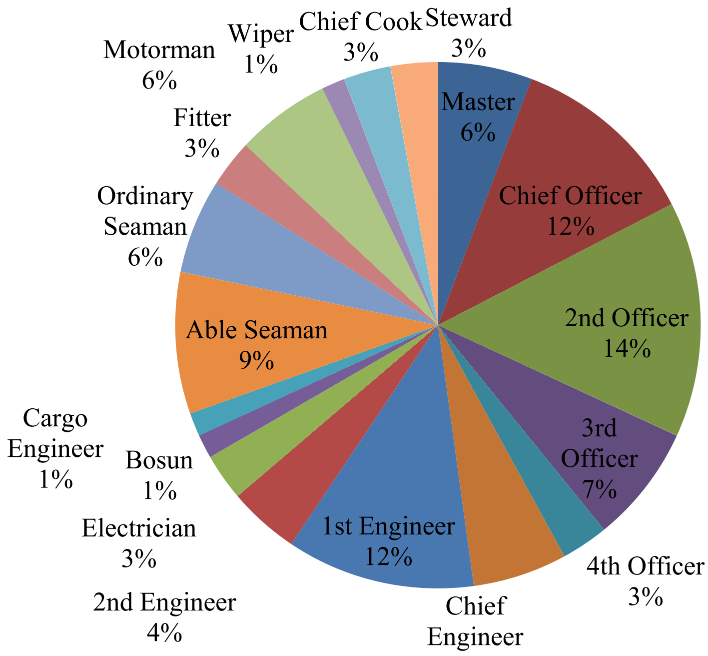

Fig. 1.
Ranks of polled seafarers
Source: Authors' own construction

Out of 70 respondents, 47% were working aboard crude oil tankers, 43% on LNG tankers, 9% aboard cruise ships/passenger vessels, 4% and 1% on bulk carriers (Fig 2).

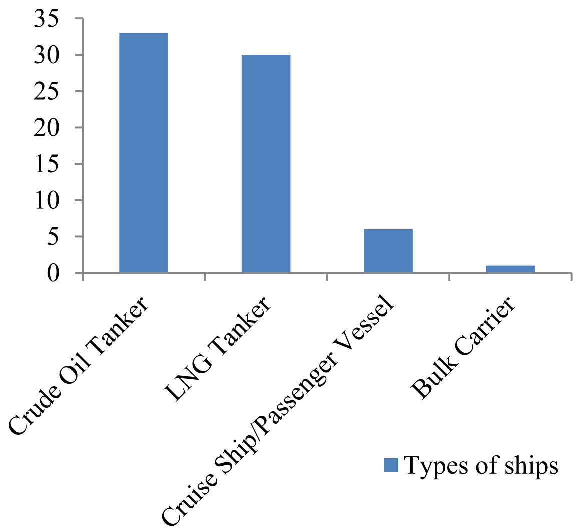

Fig. 2.
Types of ships on which respondents sail
Source: Authors' own construction

All age groups are represented in survey, majority being between 30 and 40 years old.
When asked are they or have they sailed with multicultural crew before, 99% of polled seafarers answered affirmatively.
English was official language on board all respondents ships.
When asked how well do they speak and understand the official language on board their vessels, 12% of respondents answered excellent, 40% very good, 42% good and 6 % average.
Polled seafarers answers on questions regarding attending formal Maritime English Course, Multiculturality Training and opinion about having those courses mandatory can be seen in Table 1.

Table 1
Seafarers opinion about Maritime English and Multiculturality course

Question/Answer(percentage)	Yes	No	I don't know
Have you attended Maritime English Course?	56%	44%	0%
Do you think that Maritime English course should be mandatory?	84%	10%	6%
Have you attended Multiculturality training?	41%	59%	0%
Do you think that Multiculturality training should be mandatory?	64%	32%	4%

Source: Authors' own construction

Sailing with multicultural crew is easier for 80% of polled seafarers, 9% find it more difficult than sailing with crewmembers only from their country, and 11% answered that they don't know what is easier for them.
88% of respondents answered that they don't have any difficulties understanding fellow crewmembers of different nationalities.
When asked have they experienced any accident, incident or near-miss on board their ships due to lack of communication or misunderstanding, half of respondants answered affirmatively.
When asked what do they think about multicultural understanding on board their vessel, could it be improved and how, seafarers answered variosly. Some were satisfied with present situation on board their vessels and some stated that there is always room for improvement. Few answers given by seafarers are cited below.
Seafarer 1: „Cross-cultural understanding onboard vessel is settled up by management philosophy and works well. Improvements always welcomed and should be in way of additional crew trainings given by company maritime superintendents who are in charge for management ISM."
Seafarer 2: „On this vessel cross-cultural understanding is very good. However, on my previous vessels I've experienced accidents that happened due to misunderstandings."
Seafarer 3: „It's simple give and take relationship so that we can be together with harmony."
Seafarer 4: „I believe that we understand each other very well considering the differences. Of course, there is always place for improvement. I believe that the implementation of cross-cultural training would be useful probably, however I am not sure what would be the best way for it to be the most efficient and most successful way of improving mutual understanding."
Seafarer 5: „Even though we have nine different cultures onboard we never had a cross-cultural incident, there could be improvements, in my opinion best are social gatherings and sport activities."

5. Conclusion

Influence of English on maritime industry is vast. Adequate communication in official language (English) is essential since there are more and more multicultural crews on ships. International Maritime Organization realized that and introduced standards for knowledge of English for individual ranks in their recommendations and guidelines. Inadequate knowledge of official language on board a ship can easily lead to human error that can result in an accident. Shipping companies and agencies for employement of seafarers should pay attention how their employment candidates understand English. Shore personnel that is in contact with shipboard personnel must also have adequate knowledge of official language in order to avoid communication problems and misunderstandings. According to polled seafarers, misunderstandings and inadequate communication is still factor that causes accidents. Adequate education ashore and trainings on board are essential for Maritime Safety. Multiculturality and English courses should be available for all seafarers and shore personnel. Currently available multiculturality trainings as per IMO are included in IMO Model Courses 1.22 (Ship simulator and Bridge teamwork), 2.07 (Engine-room simulator) and 1.39 (Leadership and teamwork) and they are not sufficient for fully understanding different cultures and adequate communication on board. Authors' opinion is that training about multiculturality should be standalone course.

A VISCOUS FLOW SIMULATION AROUND A FULLY APPENDED SHIP HULL BY USING A FINITE VOLUME TECHNIQUE

Adham S. Bekhit[1], Adrian Lungu[2]
[1, 2] "Dunarea de Jos" University of Galati, Faculty of Naval Architecture, Galati, Romania

Abstract: The present study is concerned with predicting the total resistance of the fully appended surface combatant DTMB5415 ship model. The study dually stands as a further step for a previous investigation of the bare-hull ship resistance that was carried out by the author, as well as an incipient investigation for the maneuvering performance prediction which is going to be carried out in the very near future. A set of computations are performed to predict the total resistance at different free stream velocities. The computations are performed by making use of the ISIS-CFD solver of the Fine^{TM}/Marine package. The solver is based on finite volume method to build the spatial discretization for solving the Reynolds-Averaged Navier-Stokes equation in a global approach. The turbulence is modeled by making use of the *k-ω SST* and EASM models. Verification and validation of the numerical solution are performed based on a grid convergence study. Computed results are compared to the towing tank measurements and show a satisfactory agreement. A dedicated investigation is based on subdividing the computational domain into its particulars to check the influence of each appendage on the total resistance of the ship. A special focus on the free-surface prediction and the local flow is also included.

Keywords: CFD, DTMB, RANS, ship resistance, viscous flow.

1. Introduction

The power required to drive the ship depends upon the resistance induced by water and air. Predicting this total resistance is one of the first steps conducted by a naval architect during the primary design stage. Obviously, accurate prediction of the total resistance is crucially important to obtain the optimum power that can satisfy the energy efficiency criteria for the proposed design. For example, merchant ships are dictated by the optimum voyage speed which can result in the highest profit for the owner on one hand, on the other hand, fuel consumption should be carefully taken into consideration, bearing in mind the fact that fuel cost is significant, while in case of warships, they are designed based their operational requirements which definitely must include high speed and optimum maneuverability. Generally, the power required for ship operations should be reduced to an optimum level by means of hull form optimization, light weight adaptation for structure and machinery, increasing fuel efficiency and/or recovering the power losses in the propeller wake region by means of energy saving devices. Clearly, implementation of one or more of these solutions can result in a significant enhancement of ship performance. Yet, it remains the challenge for the design engineer to predict the total resistance, based on which one or more of these solutions can be implemented. This returns us to the major problem in this paper, which is the prediction of the total ship drag. This requires an effective and reliable tool to predict accurately the total resistance. Formerly, reliance on model test, empirical formulas or even build and try concept was the basic method to solve this problem. Apparently, by that time these methods were considered reliable and sufficient; yet, nowadays they are completely out of fashion. Recently, Computational Fluid Dynamics (CFD hereafter) has become a very powerful tool used by researchers and designers to solve marine hydrodynamic problems. The method is also flexible for all types and sizes of ships; model or full scale, merchant or special purpose. CFD is not just suitable for predicting forces acting on the hull; it can recently be used to give clear details of local flows and free-surface, thanks to the development in viscous flow solvers and free-surface capturing techniques, which usually in a classic tank testing requires very expensive and sophisticated tools.
Investigating the capability of CFD to predict a complicated ship resistance problem, the case study in this paper is applied on the fully appended DTMB 5415 model. Taking into consideration the fact that ship is always fully appended in the normal operating conditions, investigating the total resistance for the fully appended hull is crucially important to avoid any misleading during the power computations. The DTMB hull was conceived as a preliminary design for a Navy surface combatant (SIMMAN, 2008). The bare hull geometry includes both a sonar dome and transom stern, while the appended hull includes two bilge keels, twin screw propeller shafting system supported by shaft brackets and two rudders. No full-scale ship exists, however, several tank tests were performed on this particular model and included different test cases; the bare hull was tested and presented in (Olivieri et al., 2001) and (Longo et al., 2007), besides other several investigations for seakeeping and maneuvering are also tested and presented in (IIHR, 2015). The fully appended hull is depicted in Fig. 1, while the main particulars are tabulated in table 1.

Fig. 1.

[1] Corresponding author: Adham.Bekhit@ugal.ro

The bottom view of the fully appended DTMB 5415 model

Table 1
The DTMB 5415 ship model particulars

Main Particulars	Value
Length between perpendiculars, L_{pp} [m]	5.719
Length of water line, L_{wl} [m]	5.726
Breadth Molded, B_m [m]	0.768
Draft, undisturbed free-surface elevation from base line, T_s [m]	0.248
Displacement [m^3]	0.554
Block Coefficient C_B	0.507

Several numerical simulation of the fully appended DTMB hull was also reported in the literature. For instance, a simulation for the free-surface and flow configuration around the fully appended model without the bilge keel is presented by (Lungu and Pacuraru, 2010). Another analysis for fully appended ship which included resistance and powering estimation in different advance velocities has been reported in (Voxakis, 2012). Another nonlinear study concerned with the prediction of the free-surface of the fully appended ship during self-propulsion condition was conducted by (Burg et al, 2002). In the present research a CFD technique is employed to predict the total ship resistance of the fully appended surface combatant DTMB ship model based on viscous flow simulation. Investigation of ship resistance components induced by every appendage is also presented. The free-surface configuration in different advance velocities is included and finally, the flow configuration around the hull is analyzed based on the local streamwise velocity and turbulent kinetic energy. This study stands as a second step for the bare hull ship resistance computation previously reported by the authors (Bekhit and Lungu, 2017).

2. Numerical Approach

The numerical simulation is performed by making use of the ISIS-CFD solver of the commercial software Fine^{TM}/Marine available under the NUMECA suite. The solver is based on finite volume method to build the spatial discretization for the governing equation to solve the incompressible steady Reynolds-Averaged Navier-Stokes Equation (RANSE hereafter) in a global approach (Guilmineau et al., 2015). Closure to the turbulence is achieved by making use of either the *k-ω SST* model or EASM model.

2.1. Governing Equation

For incompressible flows, if there are external forces, the averaged continuity and momentum equations are given in tensor form in the Cartesian coordinate system by

$$\frac{\partial(\rho\bar{u}_i)}{\partial x_i} = 0 \tag{1}$$

$$\frac{\partial(\rho\bar{u}_i)}{\partial t} + \frac{\partial}{\partial x_j}\left(\rho\bar{u}_i\bar{u}_j + \rho\overline{u_i'u_j'}\right) = -\frac{\partial\bar{p}}{\partial x_i} + \frac{\partial\bar{\tau}_{ij}}{\partial x_j} \tag{2}$$

where $\bar{u}_i$ is the relative averaged velocity vector of flow between the fluid and the control volume, $\overline{u_i'u_j'}$ is the Reynolds stresses, $\bar{p}$ is the mean pressure and τ_{ij} is the mean viscous stress tensor components for Newtonian fluid under incompressible flow assumption, and it can be expressed as

$$\bar{\tau}_{ij} = \mu\left(\frac{\partial\bar{u}_i}{\partial x_j} + \frac{\partial\bar{u}_j}{\partial x_i}\right) \tag{3}$$

The system of equations is closed by imposing the turbulence closure equations whether in *k-ω SST* or EASM models. More details about both turbulent modeling can be found in (Menter, 1994) and (Gatski, 1993), respectively. Pressure-velocity coupling is enforced through a Rhie & Chow SIMPLE like method: at each time step, the velocity updates come from the momentum equation and the pressure is extracted from the mass conservation constraints transformed into pressure equation (Vissoneau et al., 2016). Convection and diffusion terms in the RANSE are discretized by a second-order upwind scheme and a central difference scheme, respectively. The flow is accelerated through a steady quasi-static approach within a time-span corresponding to the relationship between the length of the ship and the inflow velocity such that $T_{acc}=2.0L_{pp}/U_\infty$. Computations are performed for 30 seconds using 10 iterations per time step, while the time step is chosen with respect to the equation $\Delta t=0.005L_{pp}/U_\infty$ for *k-ω SST* model and $\Delta t=0.001L_{pp}/U_\infty$ for EASM model as it is suggested by the ITTC recommended procedures for CFD (ITTC, 2014). The free-surface is captured in an air-water interface based on volume of fluid (VOF) method. All the computations are performed with respect to an earth-fixed Cartesian reference frame with only two degrees of freedom including heave and pitch.

2.2. Computational Domain and Discretization Grid

The computational domain is having a rectangular configuration. Dimensions of the computational domain in (x– y– z) direction are ($5.0L_{pp}$–$1.5L_{pp}$–$2.0L_{pp}$) distributed as $1.0L_{pp}$ upstream, $3.0L_{pp}$ downstream, $1.5L_{pp}$ on the side, $1.5L_{pp}$ underneath the undisturbed free-surface and 0.5 above the undisturbed free-surface level. Taking into account the symmetry of the hull and neglecting all the lateral motions, only half ship is introduced in this computation to simplify the problem and reduce the number of grid cells required. Boundary conditions are applied on the ship hull and domain boundaries as follows:

- Top and bottom: prescribed pressure, updating the hydrodynamic pressure during simulation,
- Inlet, outlet and side: far field,
- Centerline plane: symmetry,
- Ship hull and appendages: No-slip,
- Deck: slip condition, assuming that the deck will remain in the air during the computation, where viscous effect can be neglected.

Figure 2 depicts the computational domain dimensions and boundary conditions.

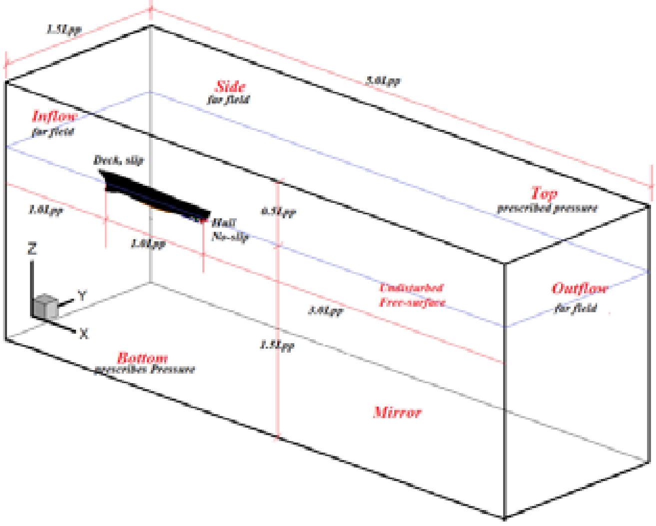

Fig. 2.
Computational domain dimensions and boundary conditions

Three computational grids are generated by making use of the unstructured automatic grid generator HEXPRESS available in the Fine^{TM}/Marine package. Table 2 summarizes the total number of grid cells for the discretization grids based on the wall treatment condition.

Table 2
Discretization grids number of cells depending on the wall treatment

Discretization Grid		Fine	Medium	Coarse
Wall treatment	Wall Modeled	2.669M	5.667M	8.958M
	Wall resolved	3.634M	9.022M	16.605M

Ensuring the grid similarity is quite difficult for such a ship due to the complicated geometry and the existence of the appendages. However, this problem is solved by imposing similar grid generation parameters and similar refinement ratios. The free-surface is refined, for medium and fine grids, in x- and y-direction according to the equation $\Delta x=\Delta y=2\pi Fr^2L_{pp}/50$, while $\Delta z= L_{pp}/1000$; where the Froude number is defined by $Fr=V/(gL_{pp})^{0.5}$. The distance to the wall is treated with two different approaches, wall modeled imposing y^+=32 and wall resolved having y^+ less than unity. The computational grid for the medium mesh is depicted in Fig. 3 highlighting the bow, stern and free-surface refinement.

3. Results and Discussion

Basically, the numerical solutions of the present paper are targeted in three main directions, namely verification and validation, velocity dependent results, free-surface and local flow solutions. In the first one, the ship velocity is set to the design velocity corresponding to *Fr*=0.28. The solution is presented for twelve sets of computations; six for *k-ω SST* model, three for wall modeled and three for wall resolved and similar for EASM for the same conditions.

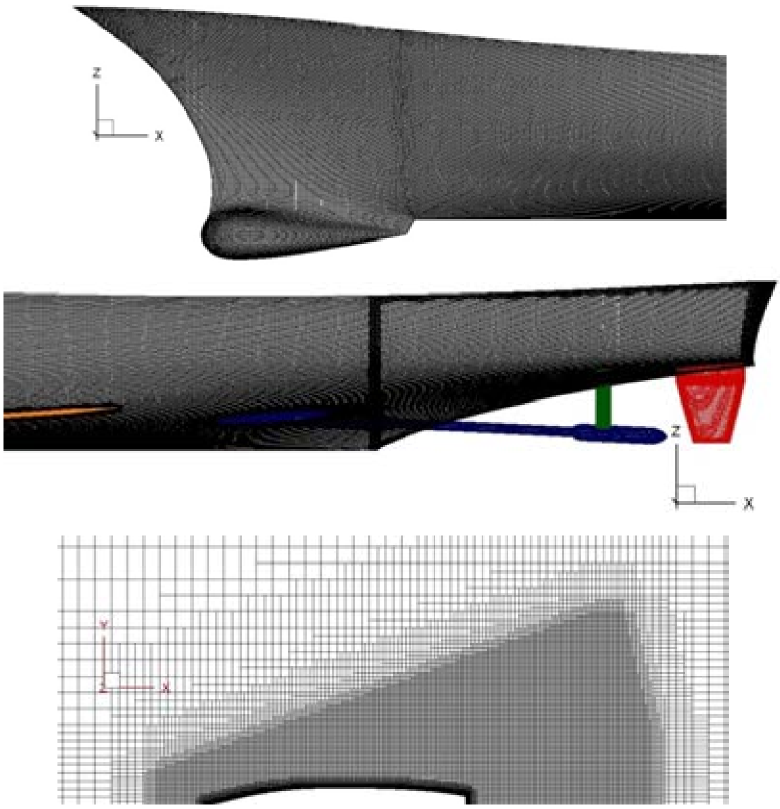

Fig. 3.
Discretization grid; bow (top), stern (middle) and free-surface (bottom)

3.1. Verification and Validation Results

Table 3 tabulates the comparison between computed and measured results, where WM is referring to wall modeled, WR is referring to wall resolved, while ε is referring the percentage relative difference between computed and measured results according to the relation: $\varepsilon=(100(CFD\text{-}EFD))/EFD$, where EFD is referring to the experimental results. M1, M2 and M3 indicate the fine, medium and coarse meshes, respectively. During the computation the hull is subdivided into its six main components: global appended hull, bare hull, bilge keel, shaft, brackets and rudders. The drag value is computed for every component individually. It is worth mentioning that the verification and validation is made based on the available bare hull results in (Olivieri et al, 2001), (Longo et al, 2007) and (Larsson et al, 2013).

Table 3
Total ship resistance coefficient C_T computed for the bare hull compared to the experimental results

Results	C_T EFD	C_T (WM), CFD		C_T (WR), CFD	
		k-ω SST	EASM	*k-ω SST*	EASM
M1	4.23×10^{-3}	4.415×10^{-3}	4.359×10^{-3}	4.057×10^{-3}	4.098×10^{-3}
ε		4.37%	3.05%	-4.09%	-3.12%
M2		4.545×10^{-3}	4.513×10^{-3}	4.293×10^{-3}	4.275×10^{-3}
ε		7.44%	6.69%	1.49%	1.06%
M3		4.561	4.551×10^{-3}	4.363×10^{-3}	4.334×10^{-3}
ε		7.82%	7.59%	3.14%	2.45%

The computed solutions show a reasonable agreement with the experimental results. The relative error range for wall modeled is varying between 4.37 and 7.82% for *k-ω SST*, while for EASM the error is between 3.05 and 7.59%, a fact that shows that for the coarsest mesh, the error is relatively significant. On the other hand, the error for the wall resolved model shows an under predicted value for the total resistance coefficient computed on the finest mesh whereas, on the opposite, the coefficient is over predicted for the other meshes. Yet, the absolute range of error remains between 1.06 and 4.09%, which can be considered as acceptable.
From the verification of results point of view, all the results are showing a monotonic convergence. However, the difference between fine and medium grid is significant compared to the difference between medium and coarse grids.

This might require an investigation of an extra grid, preferably with a density between the fine and medium grid to perform accurately the Richardson Extrapolation verification test.

3.2. Velocity Effect

For this case, the Froude number is chosen for three working conditions *Fr*=0.1, 0.28 and 0.41. These cases are computed only for the wall resolved on the medium mesh, considering the fact that the computed results showed a good agreement with the experimental results. The results also include a detailed definition for the drag force produced by hull components separately. Table 4 summarizes the resistance forces produced by the fully appended hull and hull components.

Table 4
Resistance results for the fully appended hull and for hull components individually

Fr	Turbulence Model	Hull Component Force [N]					
		Fully appended	Bare Hull	Bilge Keel	Shaft	Shaft Brackets	Rudder
0.1	*k-ω SST*	6.108	5.292	0.088	0.266	0.232	0.23
	EASM	7.184	5.402	0.112	0.302	0.15	0.21
0.28	*k-ω SST*	56.878	45.654	1.62	3.63	2.624	3.35
	EASM	55.728	45.458	1.658	3.556	2.02	3.036
0.41	*k-ω SST*	176.776	151.872	4.506	5.98	5.706	8.712
	EASM	178.528	154.156	4.586	5.654	5.748	8.384

It can be noticed from Table 4 that the bare hull ship resistance value is having a good match with the EFD results for both turbulence models. Error values, computed for bare hull as previously explained, for *Fr*=0.1 is 3.32% for *k-ω* SST and 1.31% for EASM, while at *Fr*=0.28 is 1.49% and 1.06% for *k-ω SST* and EASM, respectively and finally for *Fr*=0.41 the error values are 0.55% and 0.95% for *k-ω SST* and EASM, respectively.

Similarly, the sinkage value computed after 30 seconds for *k-ω SST* and EASM at different Froude number is tabulated in Table 5 and compared to the towing tank experimental data for the bare hull ship resistance found in (Olivieri et al, 2001). The relative sinkage error between computed and experimental results at *Fr*=0.1 is 14.9% and 14.32% for *k-ω SST* and EASM, respectively. This value is considered significant compared to the other errors obtained so far. This might be due to the poor grid quality. The other values for sinkage and trim errors at higher Froude numbers show a reasonable agreement with the computed results.

Table 4.
Sinkage and trim values computed for the fully appended hull compared to the measured value in (Olivieri et al, 2001)

Fr	Sinkage EFD	CFD		Trim EFD	CFD	
		k-ω SST	EASM		k-ω SST	EASM
0.1	0.174×10^{-3}	0.148×10^{-3}	0.149×10^{-3}	0.018	0.0192	0.0192
ε		14.9%	14.32%		6.67%	6.67%
0.28	1.82×10^{-3}	1.892×10^{-3}	1.891×10^{-3}	0.108	0.1073	0.1107
ε		3.96%	3.95%		0.65%	2.5%
0.41	4.7×10^{-3}	4.635×10^{-3}	4.642×10^{-3}	0.421	0.441	0.439
ε		1.38%	1.23%		4.75%	4.27%

3.3. Free-Surface and Local Flow Analysis

The free-surface is then computed for the three different Froude numbers for 30 seconds of simulation. Since the free-surface elevation for the fully appended ship is not provided, the comparison of the free-surface topology for a validation purpose will be made for the numerical solution in this simulation of the fully appended ship and the experimental results for the bare hull ship, assuming that, the appendages located at a sufficiently far distance from the free-surface should not have a significant effect on the free-surface topology. The comparison of the free-surface results at *Fr*=0.28 is brought into attention in Fig. 4 where the computed results are plotted versus the experimental results obtained in (Longo et al., 2007).The comparison shows a reasonable agreement with the experimental data, especially in the fore part of the ship where the appendages should have no effect on the free-surface. Heading more downstream, one can distinguish a slight difference between the computed free-surface and the measured one nearby and past the aft shoulders.

Figure 5 depicts the development of the free-surface topology corresponding to the change in the Froude number. The results reveals the aforementioned problem regarding to the cell size chosen for the *Fr*=0.1 which shows a noticeable under prediction for the free-surface around the ship. This might require an extra refinement for the free-surface grid to enhance the results. The free-surface for the other Froude numbers seems to be well developed seemingly due to a more accurate meshing in respect to the wave length. It is worth mentioning that the undisturbed free-surface is positioned at z=0.248m.

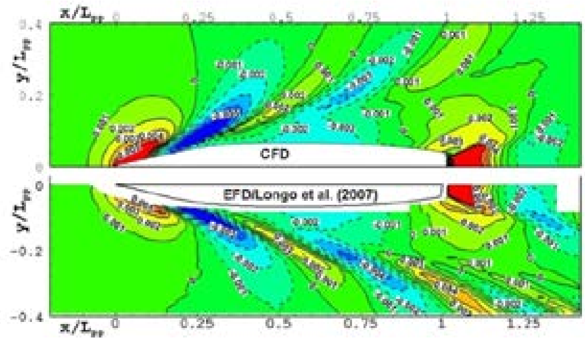

Fig. 4.
Comparison between computed free-surface at T=30 seconds for the fully appended ship and measured Free-surface for bare hull (Longo et al, 2007)

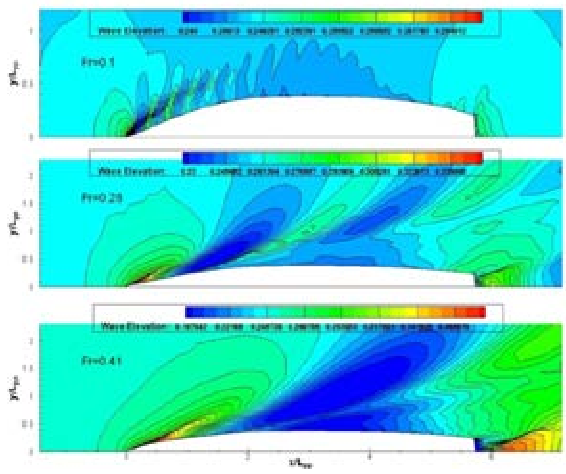

Fig. 5.
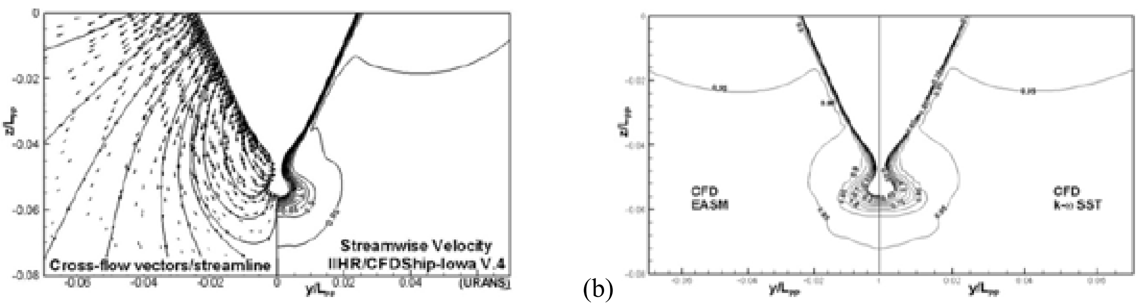
Free-surface topology computed at T=30 seconds at Fr=0.1, 0.28 and 0.41

Local flow prediction around the hull represents a significant challenge due to its complicated geometry and the existence of the appendages which tend to change dramatically the flow configuration around the hull. For a validation reason, the streamwise velocity contours are drawn in a plane distanced from the forward perpendicular at x/L_{pp}=0.1. The CFD solutions are compared with the data obtained for the bare hull in (Larsson et al, 2013), assuming that the flow before the appendages should not be significantly affected.



(a) (b)

Fig. 6.
Comparison between streamwise velocity computed at T=30 seconds k-ω SST and EASM models compared to other computed results by IIHR/CFD ship-Iowa V4
Source: (a) Gothenburg workshop on CFD in ship hydrodynamics (Larsson et al, 2013)

As it is obviously shown in Fig. 6, the agreement between the current simulation and the data provided in *(Larsson et al, 2013)* is allowing the authors to assume that the results for the rest of the wake flow should be within an acceptable level of accuracy. For this reason, three different cuts are presented in Fig. 7 for every appendage to show the flow distribution around the appendage. The distance for these sections are x/L_{pp}=0.6818, 0.9327 and 0.9948 from the forward perpendicular, respectively. The streamwise velocity contours plotted for these sections are showing the viscous effect and vortex development from the shaft as it can be seen in Fig. 7.c.

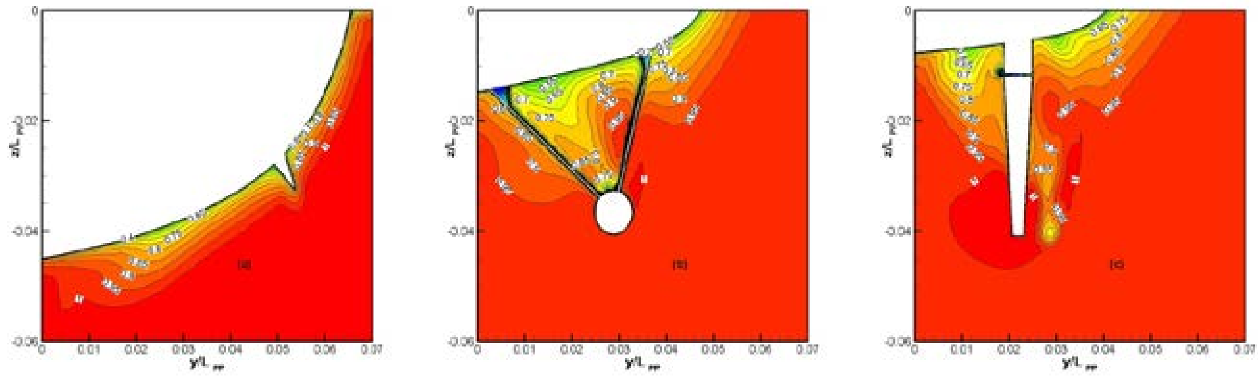


Fig. 7.
Streamwise velocity contours computed at T=30 seconds around the appendages: (a) bilge keel, (b) shaft and shaft brackets and (c) rudder

Figure 8 bears the comparison between the *k-ω* SST and EASM solutions used to predict the streamwise velocity contours and turbulent kinetic energy contours along the hull at 11 different sections distanced $\Delta x/L_{pp}$=0.1. The comparison shows the capability of both turbulence models to predict, at least at a qualitative level, the flow development around the hull. It can be noticed that the sonar dome produces a vortical structure pattern around the hull which tends to vanish in the downstream due to the viscous interaction. One more vortical configuration can be seen in the last cross-section, which is produced by the cap of the propeller shaft. The computed solutions reported in here are in a good agreement with the results previously reported (Lungu and Pacuraru, 2010).

4. Concluding Remarks

The study presented the total ship resistance prediction of the fully appended DTMB 5415 ship model. Different sets of CFD simulations were performed based on a viscous flow solver of the RANS equation where the turbulence was modeled based on *k-ω* SST and EASM models. The computed results were validated based on comparisons with the experimental results showing an encouraging agreement for ship resistance, sinkage and trim, free-surface and local flow prediction. Summing up the details presented in this study, the following concluding remarks can be drawn:

- For the total resistance prediction, the verification and validation study showed a reasonable agreement with the experimental results for the design speed and also for the different velocities; however, the verification study showed the need to analyze one more grid to enhance the results;
- The results for ship motion including sinkage and trim were well predicted except for the lowest velocity due to the fact that the refinement criteria were implied for a higher velocity, showing the need for extra refinement;
- The free-surface prediction was encouraging, except for the lowest Froude number, where the previously mentioned problem still exists;
- Local flow analysis showed a relative success in predicting the streamwise velocity contours and turbulent kinetic energy around the hull compared to experimental and previous simulations presented in the literature. The vortical structure of the sonar dome and the shaft cap were well predicted. Nevertheless, the overall accuracy of the local flow prediction can be enhanced by using local refinement nearby the hull;
- Finally, more rigorous investigation is required to enhance the overall results accuracy.

NUMERICAL STUDY OF THE RESISTANCE, FREE-SURFACE AND SELF-PROPULSION PREDICTION OF THE KVLCC2 SHIP MODEL

Adham S. Bekhit[1], Adrian Lungu[2]
[1, 2] "Dunarea de Jos" University of Galati, Faculty of Naval Architecture, Galati, Romania

Abstract: The paper proposes an alternative method totally dependent on the use of CFD simulation to solve ship hydrodynamic problems as an alternative to the classical tank tests. The case study for this paper is the modified ship model of the Kriso Very Large Crude Carrier (KVLCC2). A series of numerical investigations are performed including: ship resistance computations with and without rudder, free-surface flow prediction for the design speed, wake flow structure investigation in the stern, propeller open water simulation and finally the self-propulsion prediction for ship with and without the rudder. Results are presented and compared with the available tank test results provided in the Gothenburg 2010 Workshop on CFD in Ship Hydrodynamics to investigate the accuracy of numerical simulation in comparison with the classical methods. A comprehensive study is brought into focus for clarifying various issues such as the wake flow structure, propeller open water test, self-propulsion with and without the rudder, all aimed at achieving a better understanding of the interaction between the ship hull, propeller and rudder. The results show an encouraging overall agreement with the available experimental data.

Keywords: Free-surface flow, POW, RANS, self-propulsion, ship resistance.

1. Introduction

There is a wide range of ship hydrodynamic problems a naval architect has to deal with, starting from the fundamental ship resistance and powering problems, heading through free-surface, self-propulsion, seakeeping and maneuvering. A need for an easy, quick and reliable tool is essential for primary design stage. Traditionally, the reliance on the experimental tests was the trend until the mid-nineteenth century. In fact, the method is well recognized as the most accurate and reliable; yet, it is still very expensive and complicated. The other alternative is the theoretical based method, which can provide a quick solution for predicting ship resistance and powering based on empirical equations and formulas deducted for specific types of ships. This method is very cheap and simple to use; unfortunately, it is restricted to the ship type and sometimes dimensions. Besides, there are no details at all regarding the flow configuration around the hull or at the free-surface. Since 1960s, the computational fluid dynamics (CFD hereafter) has shown a great progress that made the CFD one of the most recognized tools nowadays used for ship design and optimization, due to its flexibility and capability to provide very good details for the flow around the ship hull. The turning point in CFD simulations started in the 1980s when the Reynolds-Averaged Navier-Stokes Equation (RANSE hereafter) method was conceived to solve the wake flow of the stern. A rigorous investigation and development started in the 1990s regarding the turbulence modeling to provide more accuracy in predicting the bilge vortices in the stern wake at the propeller. The development in the RANS solvers since that time has reached a remarkable level. Recently, the CFD method reached a top level of accuracy that encouraged the researchers to think of what so called "Simulation Based Design, SBD" techniques to replace the classical method based on experimental or theoretical based design (Stern et al, 2003).

In this paper, a CFD technique is used to solve some of the ship hydrodynamic problems including ship resistance, free-surface, wake flow prediction, propeller open water (POW, hereafter) and finally self-propulsion. The case study for this paper is the modified hull of the Kriso Very Large Crude Carrier (KVLCC2 hereafter). The ship was conceived to provide data for both explication of flow physics and CFD validation for a modern tanker ship with bulb bow and stern. The full scale ship does not exist; however, several models were built and tested by various international well recognized towing tank organizations in the world such as NMRI in Japan, INSEAN in Italy and HMRI in Korea. Several experiments were performed, including ship resistance and free-surface, seakeeping, and maneuverability. In this case study, the INSEAN ship model is used for validating this simulation which has a length between perpendiculars of 7.0m and a draft of 0.455m, while the propeller diameter is 0.204m. Full details of the ship characteristics are tabulated in Table 1, as the geometry of the ship including propeller and rudder is depicted in Fig.1.

A set of test cases is chosen in respect to the Gothenburg 2010 (Larsson et al, 2013) test cases, which comprises ship resistance of the fixed hull without the propeller or rudder, free-surface, flow configuration around the hull, ship resistance with rudder including sinkage and trim. The other set of computations includes POW simulations carried

2. Numerical Approach

The numerical simulation is performed by making use of the ISIS-CFD solver of the commercial software Fine^{TM}/Marine of NUMECA. The solver is based on finite volume method to build the spatial discretization for the governing equation to solve the incompressible steady RANSE in a global approach (Guilmineau et al, 2015). Closure to the turbulence is achieved by making use of either the *k-ω SST* model or EASM model. Pressure-velocity coupling is enforced through a Rhie & Chow SIMPLE method where the velocity updates come from the momentum equation and the pressure is extracted from the mass conservation constraints transformed into a pressure equation. Convection and diffusion terms in the RANSE are discretized by a second-order upwind scheme and a central difference scheme, respectively.

2.1. Governing Equations

For incompressible flows, if there are external forces, the averaged continuity and momentum equations are given in tensor form in the Cartesian coordinate system by:

$$\frac{\partial(\rho \bar{u}_i)}{\partial x_i} = 0 \quad (1)$$

$$\frac{\partial(\rho \bar{u}_i)}{\partial t} + \frac{\partial}{\partial x_j}\left(\rho \bar{u}_i \bar{u}_j + \rho \overline{u_i' u_j'}\right) = -\frac{\partial \bar{p}}{\partial x_i} + \frac{\partial \bar{\tau}_{ij}}{\partial x_j} \quad (2)$$

where $\bar{u}_i$ is the relative averaged velocity vector of flow between the fluid and the control volume, $\overline{u_i' u_j'}$ is the Reynolds stresses, $\bar{p}$ is the mean pressure and τ_{ij} is the mean viscous stress tensor components for Newtonian fluid under incompressible flow assumption, and it can be expressed as

$$\bar{\tau}_{ij} = \mu\left(\frac{\partial \bar{u}_i}{\partial x_j} + \frac{\partial \bar{u}_j}{\partial x_i}\right) \tag{3}$$

For resistance and self-propulsion computations, the flow is accelerated through a steady quasi-static approach within a time-span corresponding to the relationship between the length of the ship and the inflow velocity such that $T_{acc}=2.0L_{pp}/U_\infty$. Computations are performed for 30 seconds using 10 iterations per time step, while the time step is chosen with respect to the equation $\Delta t=0.005L_{pp}/U_\infty$ for *k-ω SST* model and $\Delta t=0.001L_{pp}/U_\infty$ for EASM model as it is suggested by the ITTC recommended procedures for CFD (ITTC, 2014). The free-surface is captured in an air-water interface based on volume of fluid (VOF) method. On the other hand, for the POW simulation, the solution is based on an unsteady RANSE. The flow is accelerated within 200 time steps, while the time step is chosen to provide 100 time steps per propeller complete rotation based on the rotating frame method. Only EASM is used for the POW computation, which can provide better results for the propeller wake based on the previous experience from previous simulations (Lungu, 2018). All the computations are performed in respect to an earth-fixed Cartesian reference frame.

2.2. Computational Domain and Discretization Grid

For resistance and self-propulsion simulations, the computational domain is having a rectangular configuration. Dimensions of the computational domain in (*x*–*y*–*z*) direction are ($5.0L_{pp}$–$2.0L_{pp}$–$2.0L_{pp}$) distributed as $1.0L_{pp}$ upstream, $3.0L_{pp}$ downstream, $2.0L_{pp}$ on the side, $1.5L_{pp}$ underneath the undisturbed free-surface and 0.5 above the undisturbed free-surface level. Taking into account the symmetry of the hull and neglecting all the lateral motions, only half ship is used in the ship resistance simulation to simplify the problem and reduce the number of grid cells required, while for the self-propulsion simulation, the entire ship hull is used.

The computational domain dimensions and boundary conditions for self-propulsion and POW are depicted in Fig. 2. Worth noticing the computational domain for the ship resistance computation is similar to the self-propulsion domain, except it has half the domain size in *y*-direction with a symmetry boundary condition applied on the ship centerline plan.

For POW simulation, the domain is of a cylindrical shape whose diameter is 6.0 times the propeller diameter D_p, and length is extended over $8.0D_p$. An isotropic refinement cylinder is applied in the propeller vicinity having a diameter $1.2D_p$ and extended downstream for $4.0D_p$, as described in Fig. 2. The boundary conditions applied on the boundaries are: for the inflow and cylinder side, a far field with the free stream velocity imposed, while the pressure is imposed on the outlet boundary. No slip condition is applied on the propeller solid wall, and a slip condition is applied on the propeller shaft.

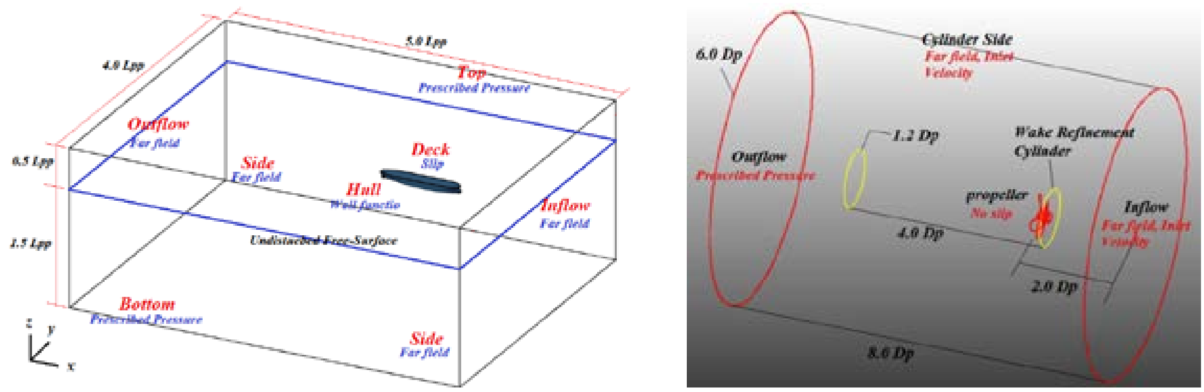

Fig. 2
Computational domain dimensions and boundary conditions: self-propulsion (left) and POW (right)

2.3. Discretization Grid

The computational grids are generated by making use of the automatic unstructured grid generator HEXPRESS available in the NUMECA software. Several sets of grids are generated and tested for bare hull, ship with rudder, POW and self-propulsion test. A local isotropic refinement is applied for the zones of interest to predict the flow characteristics, such as the wake flow region of the hull with and without rudder, the wake region of the propeller working in open water and finally for the actuator disk zone in self-propulsion simulation. Two different approaches are used to model the rudder; the real rudder modeling, which includes the semi-suspended rudder configuration with the actual stator and rotor parts and the simplified rudder which is used to eliminate the gaps between the stator and the rotor parts of the rudder to reduce the total number of grid cells during the simulation. Both methods are used to compute the solution for the design speed and shows being in a close agreement. For that, the analysis of resistance for the case of rudder is used based on the simplified rudder approach and it shows to have a good agreement with the experimental results. However, for the wake flow details, the actual rudder is used to simulate the real case problem. Details for the discretization grids are tabulated in Table 2, while the grid configuration for the ship with rudder and for the propeller in POW simulation is depicted in Fig. 3.

Table 2
Number of cells used for discretization grids

Computational Grid	Ship Resistance		POW	Self-propulsion		
	Bare hull	with simplified Rudder		Bare Hull	Simplified rudder	Actual Rudder
Number of grid cells	20.33 M	4.75 M	10.67 M	17.78 M	20.21 M	21.58 M

Discretization grid for ship with; simplified rudder (left) and actual rudder (mid) and propeller for POW test (right)

3. Results and Discussion

3.1. Resistance, Free Surface and Wake Flow

The results for resistance simulations are computed for ship with rudder including two degrees of freedom motion for sinkage and trim. The results are tabulated in Table 3 and compared to the experimental results showing a good agreement especially for case when turbulence is modeled using EASM. The relative error is computed based on the equation $\varepsilon = (100(EFD\text{-}CFD))/EFD$, where EFD refers to the experimental results while CFD refers to the computed ones. The maximum error in case for *k-ω* is within 7.5% while for EASM is about 4%. The results for sinkage and trim showed a relative similarity for both turbulence models; hence, the results are presented only for EASM results. The errors for sinkage and trim are significantly higher for lower ship velocities while it is within an acceptable range for higher velocities. This might be due to the fact that the free-surface refinement is chosen for a higher Froude number which tends to act as a wave damper wherever the velocity gets smaller, a fact that might change the water elevation around the hull, which leads to this increment in sinkage and trim errors. The Froude number is defined by $Fr=V/(gL_{pp})^{0.5}$.
The free surface results can be visualized in Fig. 4. The qualitative comparison for the free-surface topology is presented in Fig. 4a and compared to the EFD results provided in (Kim et al, 2001), while the quantitative results are plotted in Fig. 4b comparing the wave elevation at different cuts in the lateral direction distanced at y/L_{pp}=-0.0964 and -0.1581 from the hull. It can be clearly noticed that the computed results qualitatively and quantitatively are in a satisfying agreement with the EFD results.

Table 3
Resistance, sinkage and trim results compared to experimental results in (Larsson et al., 2013)

Fr		0.101	0.1194	0.1377	0.1423	0.1469	0.1515
Resistance C_T x10^3	**EFD**	4.237	4.146	4.071	4.056	4.046	4.037

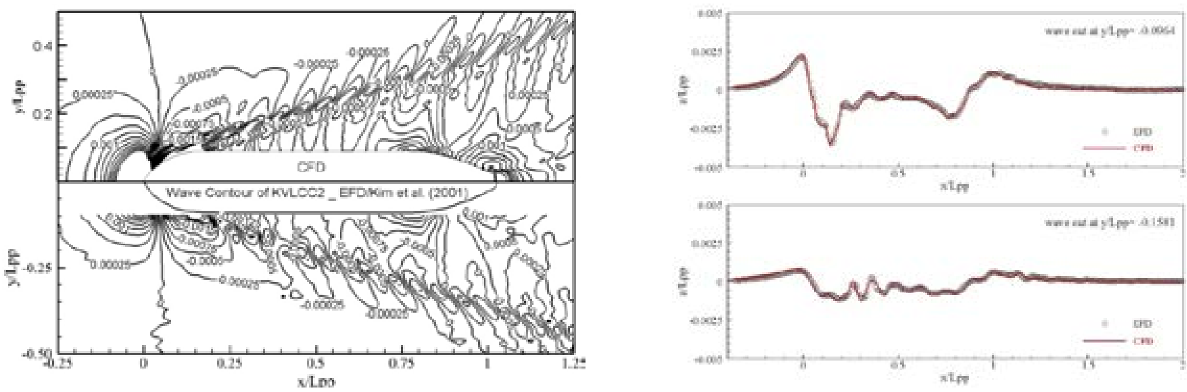

Fig. 4.
Free surface topology (left), and wave cuts at y/L_{pp}=-0.0964 and -0.1581(right)

Studying the stern wake flow can be very effective in enhancing the quality of the propeller design. The wake flow for this ship is characterized by the large distortion of the axial flow velocity contours caused by the stern vortices of the bilge resulting in the so-called “hook shape”. For a validation purpose, the development of the wake in the stern of the ship is compared with the experimental results at two different locations before and at the propeller plane placed at *x/L_{pp}*=0.85 and *x/Lpp*=0.9825, respectively. Though the contours are showing a slight under prediction of the streamwise velocity, the overall accuracy is satisfactory.

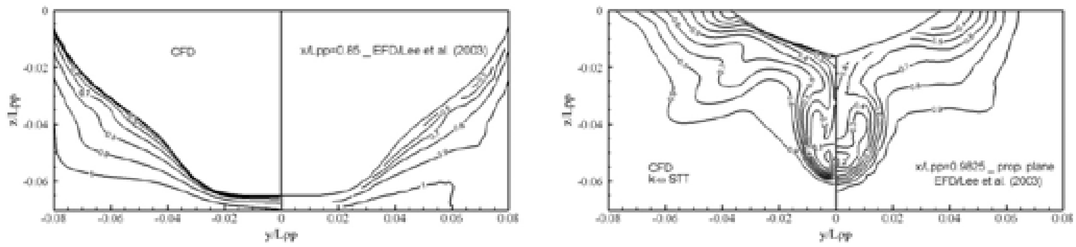

Fig. 5.
Streamwise velocity contours in x-direction at x/L_{pp}=0.85 and 0.9825 compared to EFD results

For the sake of getting a better insight into the wake flow, more details of the wake development in the stern is drawn in Fig. 6 for the locations chosen before and after the propeller for the velocity contours and the turbulent kinetic energy. The development of the vortices can be clearly seen in Fig. 6, where the first core of vortices structure starts at the stern bilge, a second vortical structure rises from the flow separation at the ship boss. Later, the two vortices are combined together and dissipate downstream due to the viscous diffusion.

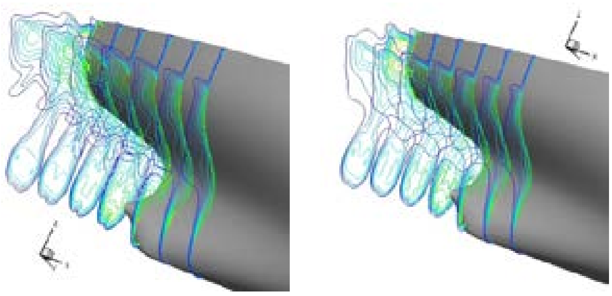

Fig. 6a.
Streamwise velocity contours at the stern using k-ω SST (left) and EASM (right)

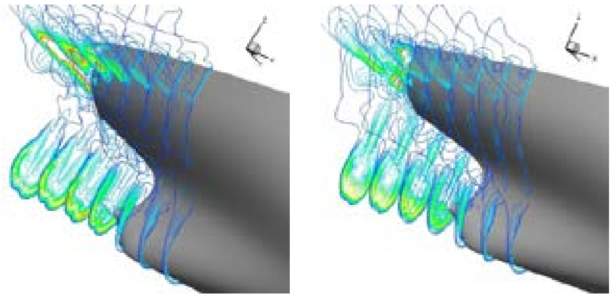

Fig. 6b.
Turbulent kinetic energy contours at the stern using k-ω SST (left) and EASM (right)

3.2 POW

The propeller model E689 is used for this study. The inflow velocity is kept constant, while the propeller rotation was changed accordingly to provide seven different values for the advance coefficient from J =0.1 to 0.7. The simulation is performed for 5 seconds and the thrust and torque coefficient K_T and K_Q are computed and compared to the experimental results. The comparison between the propeller performance curves can be visualized in Fig. 7. The average error for the thrust coefficient K_T is about 2.83% compared to the experimental results, while the average error for the torque coefficient K_Q is about 6.87%. The CFD results are in a reasonable agreement with the EFD except for the lower values of the advance coefficient where the slope of the K_Q noticeably differs.

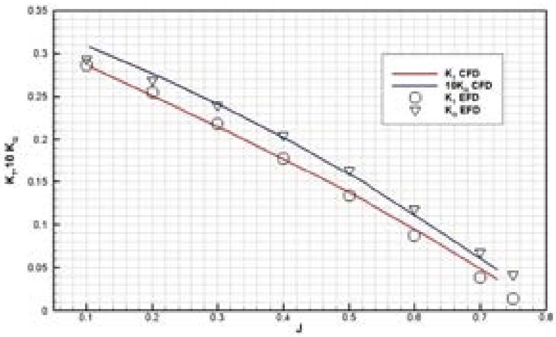

Fig. 7.
Open water propeller performance curves comparing CFD results with EFD

The study of propeller wake is influenced with different parameters; one of the most important factors is the vortices of the propeller which can result in a loss of energy, vibration or noise. The vortices generated by the propeller and their development in the wake region is depicted in Fig. 8, based on the iso-surface second invariant Q=50 colored by non-dimensional helicity, for three different cases corresponding to three different advance coefficients namely J=0.1, 0.4 and 0.7, respectively. Generally, the vortices show three types of spiral like structures; the first is released by the blade tips, the second by the propeller root and the third originates from the propeller hub. The intensity of the tip vortices seems to be higher than the intensity of the other ones. It can also be noticed that the hub vortices are suffering a local distortion in the downstream due to the significant change in the pressure and velocity in the far field and because of the viscous diffusion with the surrounding fluid downstream. The configuration of the vortical structures shows that its intensity and stability is affected by the propeller rotation, for higher advance coefficients the spiral structure seems to be more stable than that for lower ones.

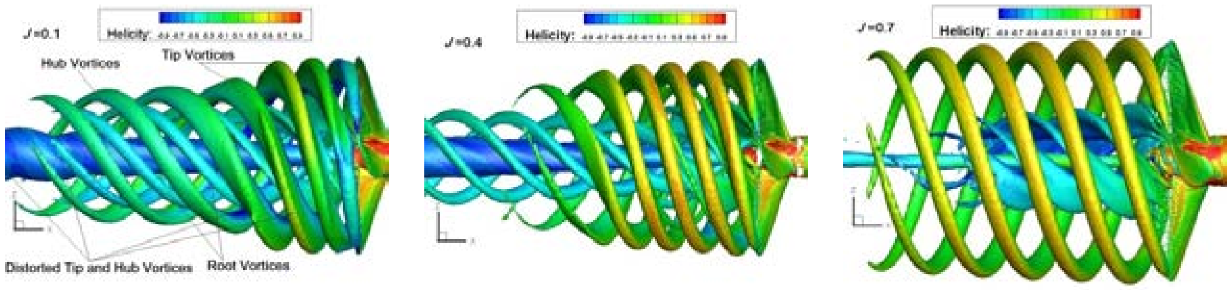

Fig. 8.
Vortical structure of the iso-surface Q=50 for J=0.1, 0.4 and 0.7 colored by non-dimensional helicity

3.3 Self-Propulsion

The simple body-force method is used to solve the self-propulsion in this study. The propeller is modeled as an infinite blade actuator disk instead of the actual propeller to simplify the problem and to increase the computational efficiency. The principle in the model is based on coupling the nominal wake obtained from RANSE solver with the open water data to solve the propeller behavior behind the ship. More details can be found in (Stern, 1994). The problem is solved for three different cases; bare hull ship, with simplified rudder model and ship with actual rudder, as previously described. The CFD results are computed for the self-propulsion parameters and compared with EFD results retrieved from (Win, 2014). Table 4 summarizes the comparison between CFD results and EFD results showing a reasonable agreement.

Table 4
Self-propulsion coefficients computed for ship with and without rudder compared to EFD results (Win, 2014)

Coefficient	Bare hull			With simplified rudder			With actual rudder		
	EFD	CFD	ε	EFD	CFD	ε	EFD	CFD	ε
Thrust coefficient, K_T	0.195	0.1983	-1.69%	0.198	0.208	5.05%	0.198	0.2022	2.12%
Torque coefficient, $10K_Q$	0.266	0.2307	-13.27%	0.228	0.2357	3.37%	0.228	0.2307	1.18%

For validation purpose, the effective wake including the interaction between hull-propeller-rudder is brought to attention in Fig. 9 for the streamwise velocity contours in *x*-direction at two selected sections in the wake region; at x/L_{pp}=1.0 and 1.025 from the forward perpendicular, respectively. The comparison shows a good agreement between CFD and EFD results.

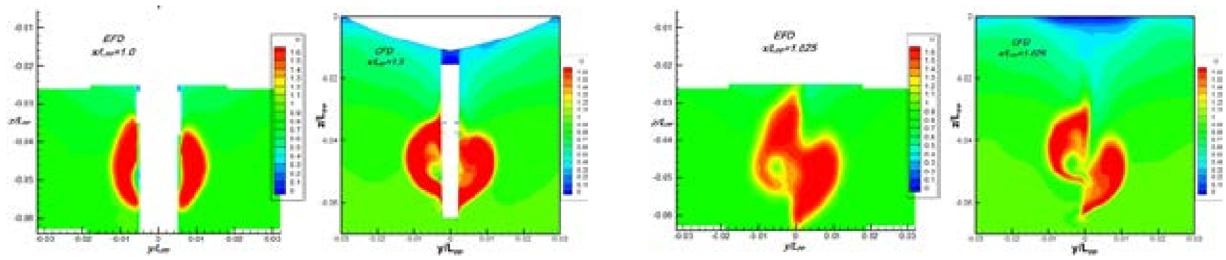

Fig. 9.
Streamwise velocity contours comparison between CFD and EFD

A closer look at the vortices in self-propulsion condition which can provide an explanation for the flow around the hull, propeller and rudder is plotted in Fig.10 for the second invariant iso-surface Q=100 colored by non-dimensional helicity. The vortices include three different vortical structures; the bilge vortices, the actuator disk tip vortices and the rudder leading edge vortices. The velocity and pressure distribution are also presented in Fig. 10 due to the correlation between velocity and pressure fluctuation that is considered as one of the reasons of generating the vortices.

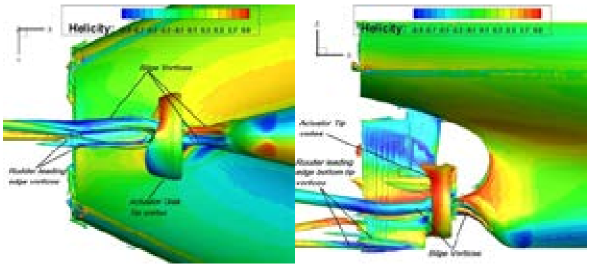

Fig. 10a.
Vortices structure bottom and side view

Velocity and pressure distribution at the stern

4. Conclusion Remarks

The objective of this paper was to investigate the versatility of the CFD tool to provide an alternate solution in the primary design stage of a ship compared to the experimental based methods. The objective was achieved by performing different simulations for different problems including ship resistance, free-surface, POW and self-propulsion. From the presented study, the following conclusions may be put forward:

- The resistance simulation showed that the EASM is having a higher level of accuracy with an error range between 2.1 and 4.01% compared to *k-ω SST* model which had an error range between 6.4 and 7.4%. Further enhancement of the computed results for both models can be achieved through extra verification and validation studies.
- Free-surface and local flow prediction showed to have a reasonable agreement with the EFD data, for both turbulence models.
- In POW simulation, average error for K_T is about 2.83% and for K_Q is about 6.87%, which can be considered as acceptable.
- In the self-propulsion simulation, the computed propulsion coefficients as well as the wake flow structure showed a noticeable agreement with the EFD results.

The overall agreement between CFD and EFD is satisfactory; yet, more rigorous validation studies are required.

NUMERICAL SIMULATION OF THE HYDRODYNAMIC PERFORMANCES OF A SHIP MOVING IN ONCOMING WAVES

Adrian Lungu[1]
[1] *"Dunarea de Jos" University of Galati, Romania*

Abstract: The Energy Efficiency Operational Indicator introduced by the International Maritime Organization as a method for monitoring the operational performance of a ship enables an assessment of the operational energy efficiency of a ship, which is expressed in terms of the CO_2 emitted per unit of transport work. Similarly, additional regulations related to the control of SO_x, NO_x, CO_2 emissions were introduced to monitor the fuel reduction through slow steaming, and improving or at least maintaining propulsive efficiency. Due to these regulations, CFD estimations become necessary therefore they gain more attention in the initial design stage. As a result, the CFD methods shifted from well validated steady resistance to more complex problems such as seakeeping and maneuvering. Since one of the main challenges is the accurate assessment of the added resistance of a ship in waves, the present work proposes a way of investigation the seakeeping performances for the KRISO Container Ship (KCS hereafter). The reason for choosing the KCS hull resides in the wide range of experimental and simulation data available for comparison and for verification and validation (V&V hereafter) of the method proposed in the present study. Five test cases of the ship model heaving and pitching in head seas are simulated at model scale. Special attention is given to the added resistance in waves since it may account for up to 15-30% of the total resistance in calm water. Validation is performed by comparing mean to fourth order harmonics of added resistance, heave and pitch motions with experimental data, while the verification is accomplished through a systematic grid refinement.

Keywords: Free-surface viscous flow, seakeeping, RANSE VOF.

1. Introduction

Understanding a ship behavior in real navigation conditions is important for estimating its hydrodynamic performances. Rough sea conditions leads to significant ship motions, which ultimately affect not only the ship resistance but also the propulsive efficiency. Since the fuel cost accounts for at least a half of the total operating costs, the problem becomes crucially important from economical point of view. Besides, the safety of the transported goods as well as the crew members' comfort on board are other important issues that motivate the need of a thorough insight into the subject. There are several ways to predict ship motions and added resistance in waves, including experiments, potential theories, and viscous flow solutions. The latter has gained popularity in the past decade due to a more physics-based modeling, capability of handling non-linear free-surface, especially for large amplitude waves and induced violent ship motions and breaking waves associated phenomena. Although at the beginning of the present century the theoretical approaches of the seakeeping were mostly based on the strip theory, mainly owing to its fast solution in spite of their drawbacks shown whenever were used for long incident waves or at high Froude numbers. The disagreements between strip theory and experiments for higher speed vessels, or geometric complicated hull forms, have therefore motivated research to develop and apply more advanced theories. A step forward has been made since the 3-D Rankine panel method began to be widely used in the numerical simulation with relative success at yet low computational costs. However, since important mon-linear phenomena that take usually place such as the wave breaking or the green-water occurrence cannot be predicted, another step had to be taken towards the use of the RANSE-based simulations. Several significant achievements were therefore reported in the past decade targeting not only to the resistance and powering computations of the full- and model-scale self-propelled hulls free to sink and trim, but also to the accurate prediction of the seakeeping performances at both full and model scale along with maneuvering calculations.

In the followings, a brief summary of the most important achievements will be provided. Lungu and Pacuraru performed a viscous free-surface flow simulation (2009) in which the solution of a RANS solver was coupled with a body force method in an attempt to investigate the flow features around a maneuvering containership equipped with a rotating propeller and rudder. Simonsen and Stern (2010) performed a comprehensive RANSE-based numerical simulations by using the CFDShip-Iowa code to obtain the heave and pitch motions and added resistance for the KCS model and the reported solutions proved to be accurate enough to motivate the effort paid. Enger et al. (2010) studied the dynamic trim, sinkage and resistance analyses of the model KCS by using the Star-CCM+ package. In their work, it was proven that the numerical solution agreed with the experimental data available in the public domain. In 2011 Carrica et al. reported two sets of computations for the KCS hull at model scale based on the use of the CFDShip-Iowa. The authors performed self-propulsion free to sink and trim simulations in calm water, followed by pitch and heave simulations in regular head waves, covering three conditions at two different Froude numbers of 0.26 and 0.33 respectively. Kim reported also in 2011 the results of the simulations performed on a 6500 TEU container carrier, being focusing on the global ship motions validated against the model test measurements. Later, Simonsen et al. (2013) investigated ship motions, flow field and resistance for an appended KCS model in calm water and regular head waves both experimentally and numerically. The authors focused mainly on large amplitude motions, and hence studied the near resonance and maximum excitation conditions. The results obtained using the CFD methods were compared to those from its experiments to show a satisfactory overall agreement. Similarly, Sadat-Hosseini et al. (2013) compared and verified the results from a CFD method and experimental for the KVLCC2 hulls in two different cases, i.e., with and without pitch

[1] Corresponding author: adrian.lungu@ugal.ro

motion. Tezdogan et al. (2015) compared the CFD viscous computation solution with the experimental data measured on the model KCS, then reported the results to the full-scale KCS in low-speed sailing, to investigate the differences. Although a great deal of promising results were reported, the prediction of added resistance is still difficult. At the 2010 Gothenburg Workshop (Larsson et al., 2013) and the 2015 Tokyo Workshop (Larsson et al., 2015), multiple researchers computed the added resistance of different ship hulls, and through cross-comparisons of the numerical solutions revealed that there is still enough room for further developments of the actual methods. Recently, the OpenFOAM open-source technique is rapidly gaining ground in various ship hydrodynamics applications. Among them some were already reporting encouraging progress. For instance, Park et al. (2013) developed SNUFOAM based on the use of OpenFOAM open source libraries to marine applications. Shen and Wan (2013) developed naoe-FOAM-SJTU and predicted added resistance at various wave stiffnesses. Shen et al. (2015) implemented dynamic overset grid technique into OpenFOAM to study the self-propulsion and maneuvering for the KCS model. Seo et al. (2016) reviewed numerical uncertainty for grid size, time step, and iteration number and identified the OpenFOAM uncertainty for a ship resistance simulation. An interesting study belongs to Vukcevic et al. (2016a, 2016b), who proposed a fluid dynamic hybrid model that combines a non-viscous computer code with a viscous one in an attempt to ensure both the efficiency and the accuracy of the solution.
The present research continues former numerical investigations on the KCS ship model reported by the author, which were aimed at computing ship resistance, the open water non-cavitating propeller (Lungu 2018a) and the cavitation on the K505 propeller (Lungu 2018b). The study is performed according to the requirements of the 2015 Tokyo Workshop (Larsson et al., 2015) for a ship moving in head waves at a Froude number of 0.261 in calm water and for a series of five oncoming waves of different wave lengths and heights.

2. Numerical Approach

The numerical solutions reported in the present paper are computed with the ISIS-CFD flow solver, part of the Numeca Fine^{TM}/Marine suite. Turbulent flow is simulated by solving the unsteady RANSE. The flow solver is based on finite volume method, which builds up the spatial discretization of the transport equations. The velocity field is obtained from the momentum conservation equations and the pressure field is extracted either from the mass conservation constraint, or from the continuity equation, transformed into a pressure equation. For turbulent flows the additional transport equations are discretized and then solved using the same strategy. The gradients are computed with an approach based on the Gauss theorem. A non-orthogonal correction technique is applied to ensure a formal second order accuracy. Inviscid fluxes are computed with a piecewise linear reconstruction associated with a stabilizing procedure which ensures a second order formal accuracy when flux limiter is not applied. Viscous fluxes are computed with central difference schemes. Based on the mesh quality, the model assures a second order discretization for the viscous term. Free-surface flow is simulated with a multi-phase volume of fluid approach. Incompressible and non-miscible flow phases are modeled through the use of conservation equations for each volume fraction of phase/fluid. An implicit scheme is applied for the discretization in time whereas a second order three-level time scheme is used for time-accurate unsteady computation. Velocity-pressure coupling is handled with a SIMPLE like approach. Although the free motion of the ship can be simulated with a 6 degrees of freedom (DOF hereafter) module, three degrees of freedom are kept fixed. An adaptive mesh refinement is employed for the seakeeping computations inside a hexahedral domain comprising the free-body and the free-surface. The EASM model is used for the turbulence closure and a viscous boundary layer consisting on 18 cells is introduced to keep the $y+$ below unity. All the computations are performed at the model scale and distributed over 120 processors. The length between perpendiculars (L_{pp} hereafter) of the model is 6.0702 m, while the maximum beam of waterline, and the draught are 0.8498 m and 0.285 m, respectively. The geometry of the hull and rudder are those officially provided by Larsson et al. (2015). Nine different grids are generated by the unstructured grid generator HEXPRESS^{TM} based on the provided geometry. Buffer cells as well as consistent inflation are used for achieving as high as possible quality cells inside the boundary layer regions for which the y^+ was kept below unity in most of the computations performed. Areas of a higher cell density are placed wherever the gradients of the computed physical parameters are expected to occur, i.e. around the ship hull and the free-surface of the water as Fig. 1 shows. Four grids denoted by $G1_{SK}$ to $G4_{SK}$ are generated at first for the grid convergence test. The $G1_{SK}$ grid is the coarsest one and consists of 3.46×10^6 cells, while the $G4_{SK}$ grid is the finest, which amounts 27.69×10^6 cells. In between the two, grid $G2_{SK}$ has 6.91×10^6 cells, whereas the $G3_{SK}$ grid has 13.86×10^6 cells. A wave damping zone has been inserted downstream and on the side of the domain, following the model described by Lungu and Mori (1993).

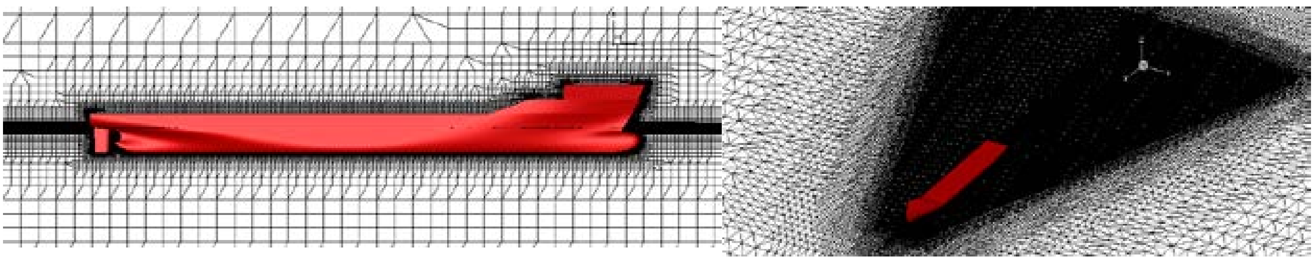

Fig. 1.
Computational Grid Around The Hull (Left) and on the Free Surface (Right)

2.1. Grid Convergence Test

At first, a series of four different unsteady computations in calm water at a speed of 2.017 m/s, to which the corresponding Froude number is 0.26, are performed on the $G1_{SK}$ to $G4_{SK}$ grids for verification and validation of the method purposes. The numerical solutions for the total resistance coefficient, sinkage and trim are tabulated in Table 1, where the computational case is denoted by C_0. The numerical solution computed in here is denoted by CFD whereas the experiment is denoted by EFD. As expected, Table 1 shows that the increase of the mesh resolution determines a reduction of the absolute computed error from 3.01 to 0.19 percent for the C_T, from 5.83 to 1.96% for the sinkage and from 8.02 to 2.13% for the trim angle. The higher levels of sinkage and trim errors compared to the corresponding one for the total resistance coefficient are attributable to the numerical technique, which did not employed any grid refinement neither close to the hull nor to the free surface, as it will be the case in the following simulations devoted to the seakeeping study. Although the level of the computed error may be considered as acceptable from an engineering point of view, it is worth mentioning that it is higher than the corresponding one for the solution computed in the previous work of the author, Lungu (2018b), in which a different size of the model was used. The difference may be attributable to the sensitivity the solver seemingly has on the scale of the model, as accepted by its authors, see Visonneau et al. (2006).

Table 1
Mean Values of the Total Resistance Coefficient (C_T), Sinkage (z), and Trim (θ) in Calm Water

C_0	Total resistance coefficient C_T				Sinkage z				Trim θ			
	Mean value ×10^3				Mean value ($/L_{PP}$)				Mean value [deg.]			
CFD	$G1_{SK}$	$G2_{SK}$	$G3_{SK}$	$G4_{SK}$	$G1_{SK}$	$G2_{SK}$	$G3_{SK}$	$G4_{SK}$	$G1_{SK}$	$G2_{SK}$	$G3_{SK}$	$G4_{SK}$
	3.7196	3.7385	3.7451	3.8422	-0.00195	-0.00196	-0.00201	-0.00203	-0.1514	-0.1576	-0.1584	-0.1611
EFD	3.835				-0.002070667				-0.1646			
ε %	3.01%	2.52%	2.34%	-0.19%	5.83%	5.34%	2.93%	1.96%	8.02%	4.25%	3.77%	2.13%

Fig. 2 bears out the free surface topology for the calm-water simulation performed on the $G4_{SK}$ mesh. It is worth noticing that both wave systems, i.e. diverging and transversal ones, are successfully captured. No wave reflections are detected on the downstream and lateral boundaries, a fact that may suggest not only the appropriateness of the boundary conditions formulation, but also the efficiency of the wave damper introduced there. As expected, two significant wave crests are detected in the immediate vicinity of the bow and right behind the hull transom.

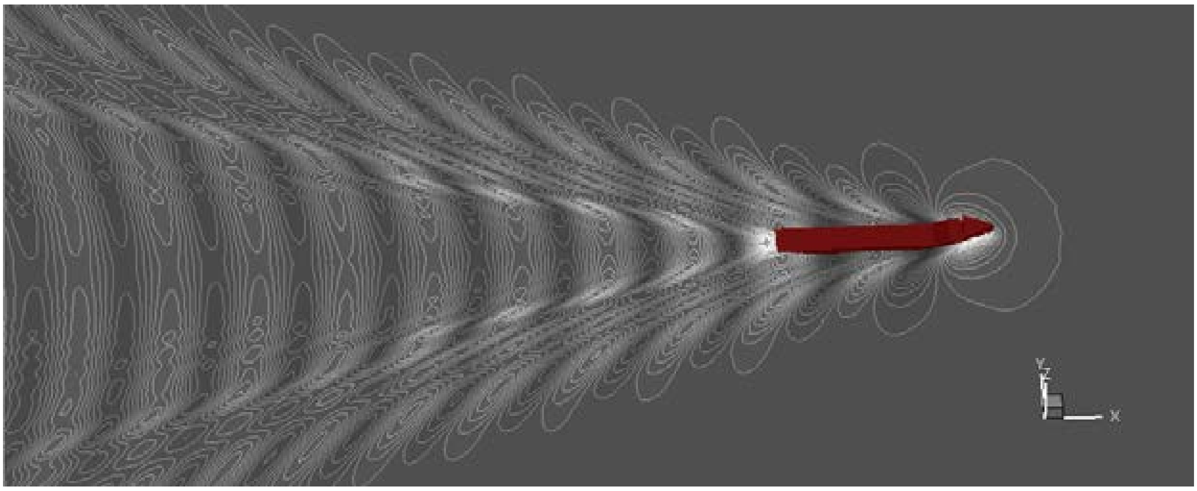

Fig. 2.
Computed Free-Surface Topology Around the Ship Hull

Based on the grid convergence test findings, in the followings all the seakeeping computations will be performed on the $G4_{SK}$ mesh only, slightly modified from the cells number point of view, from case to case, depending on the incident wave lengths and heights.

3. Seakeeping Results and Discussions

A series of five computations are performed to numerically simulate the model behavior in different oncoming wave 3DOF scenario. The heave and pitch motions are reported to the center of gravity of the hull and the wave crest at FP when t=0. The parameters of the five oncoming waves are: (a) - λ=3.949 m, Hs=0.062m; (b) - λ=5.164 m, Hs=0.078m; (c) - λ=6.979 m, Hs=0.123m; (d) - λ=8.321 m, Hs=0.149m and (e) - λ=11.840 m, Hs=0.196 m. Let these test conditions be denoted by $C_1 \ldots C_5$, for which the ratios between the wave length λ and the L_{pp} are 0.65, 0.85, 1.15, 1.37 and 1.95, respectively. The numerical analysis is further performed in terms of the harmonic amplitudes and harmonic phases of the total resistance coefficient (C_T), heave motion ($z/\zeta s$) and pitch angle ($\theta/k\zeta s$), which are reconstructed from the Fourier series. Because of the limited space reasons only the C_0 and C_5 solutions will be discussed in the following three subsections of the paper. The corresponding free-surface topologies computed for the aforementioned solutions are depicted in Fig. 3 and Fig. 4, respectively. The reason for the author's choice is that the two computational conditions are the most difficult to obtain since the wave heights are at extremities. That is, the smallest one requires a special attention from the meshing point of view, whereas the largest one is witnessing strong non-linear effects as possible green water embarking on the deck.

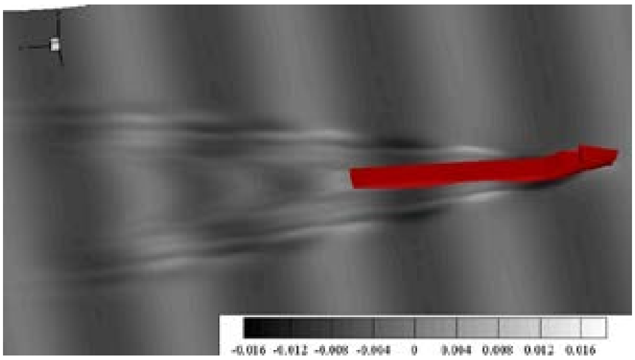

Fig. 3.
Computed free-surface the ship hull for the C1 computational scenario (oncoming wave of λ/Lpp=0.65)

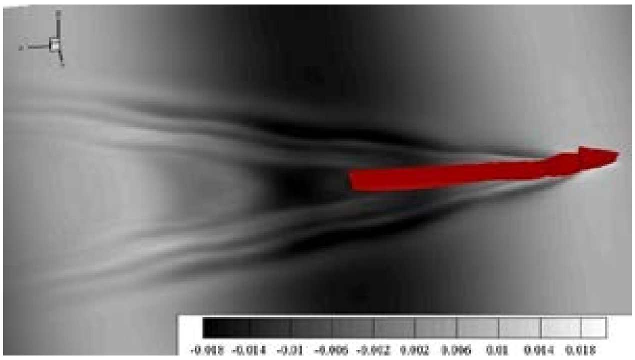

Fig. 4.
Computed free-surface the ship hull for the C1 computational scenario (oncoming wave of λ/Lpp=1.95)

3.1 Amplitudes and Phases of the Total Resistance Coefficient

Table 2 contains the comparisons between the Fourier decomposition of the computed solution denoted by CFD and the corresponding measured one by Larsson et al. (2015) for the two computational scenarios considered in here. Fig. 5 depicts the Fourier decomposition graphs for the total resistance coefficient for the two non-dimensional wave lengths considered in the present paper. The comparison performed in terms of the amplitude and phase reveals a level of errors ranging from 1.34% and 13.41% for amplitude and from 2.72% and 6.81% for phase. In both cases the largest departures correspond to the 3rd and 4th harmonics, seemingly due to the fact that the amplitudes 3rd and 4th harmonics are small compared to the amplitude of the 0th and 1st harmonics and consequently more difficult to capture, as Fig. 5 clearly shows. Nevertheless, it is worth noticing that the solutions reported in the present work are far less than those reported by Larsson et al. (2015), a fact that may suggest the accuracy of the computational method employed. The analysis of the 10 solution submitted to the Tokyo Workshop revealed an absolute average error for the 0th harmonic of 4.72% for the C_1 computational case and of 6.12% for the one denoted by C_5. For the first harmonic the comparison between the solutions submitted at the 2015 Tokyo Workshop and the experimental data revealed absolute average errors of 20.04% for λ/Lpp=0.65 and 11.97% for λ/Lpp=1.95. In terms of phase absolute errors, they varied from 4.45% to 5.20% for the first harmonics computed for λ/Lpp=0.65 and from 10.06% to 13.07% for λ/Lpp=1.95 for the 2nd harmonics.

Table 2
Harmonic Amplitudes and Harmonic Phases of the Total Resistance Coefficient (C_T)

C₁	C_T (λ=3.949 m, *Hs*=62 mm)								
	Amplitude×10^3					Phase [rad]			
	0th	1st	2nd	3rd	4th	1st	2nd	3rd	4th
EFD	8.253	3.324	0.523	0.22	0.049	-1.0836	-0.6312	-2.7490	2.3787
CFD	8.1121	3.1911	0.5011	0.1915	0.0421	-1.0516	-0.6098	-2.6129	2.4701
ε %	1.71%	3.99%	4.18%	13.11%	13.41%	2.95%	3.39%	4.95%	-3.84%
C₅	C_T (λ=11.84 m, *Hs*=196 mm)								
	Amplitude×10^3					Phase [rad]			
	0th	1st	2nd	3rd	4th	1st	2nd	3rd	4th
EFD	10.842	25.101	0.655	0.581	0.595	-0.3585	0.0890	1.5306	-0.8437
CFD	10.696	25.488	0.619	0.552	0.551	-0.3488	0.0842	1.6218	-0.9011
ε %	1.34%	-1.54%	5.50%	5.07%	7.33%	2.72%	5.42%	-5.96%	-6.81%

Comparing these figures with those tabulated in Table 2, one may conclude that the present model could simulate properly the flow since the absolute error is even four times smaller than that reported in 2015. In the opinion of the author this could be achieved only by making use of some numerical special treatment. Firstly, the unsteady approach is used with a time step corresponding to 1500 to 2000 time steps per wave period. Then, a 3D adaptive grid refinement is performed every 25 time steps inside the whole computational domain, so that the Courant number could be kept below

0.27 everywhere inside, regardless the cell position in respect to the hull or the free surface. Next, the number of the iterations used in computing the pressure is increased to 1000 while the convergence criterion is raised up to four orders. Obviously the computational cost of the simulation increased by almost an order of magnitude, but the level of accuracy attained may justify the effort spent for the purpose. The accuracy level can be proved by the good agreement shown in Fig. 6 proposes a comparison of the time history of the computed total resistance coefficient against the measured one for the two computational scenarios considered. T_e in the abscissa of the figure represents the wave encounter period, i.e. $1/f_e$, where $f_e = \sqrt{g/(2\pi\lambda)} + U/\lambda$ is the wave encounter frequency. In the equation above U stands for the ship speed. Both aforementioned comparisons reveal only slight departures in amplitudes but with no significant phase-shift.

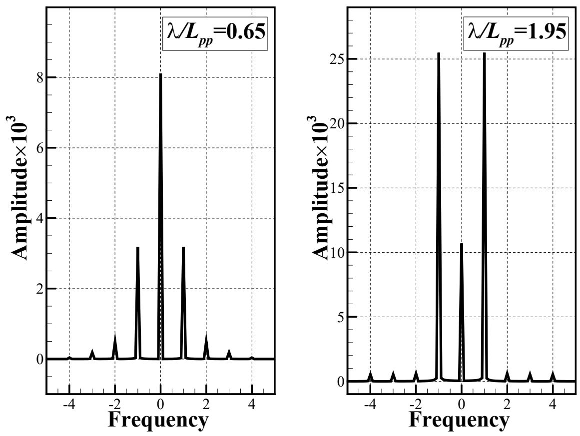

Fig. 5. *Fourier decomposition for the C_T amplitude: left: λ/Lpp=0.65; right: λ/Lpp=1.95*

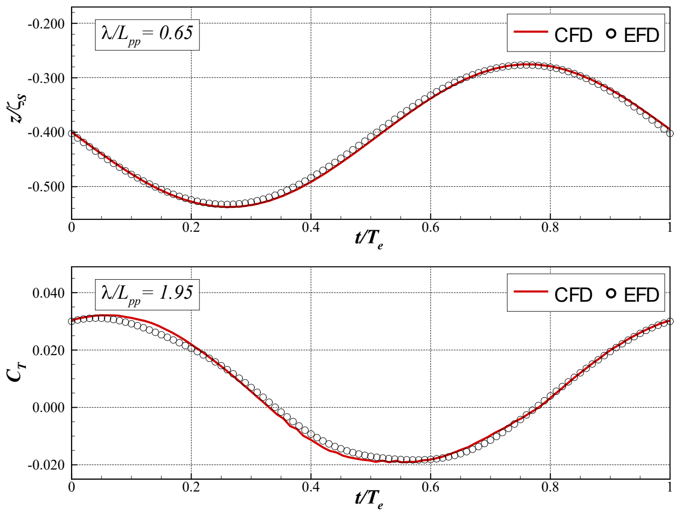

Fig. 6. *Time history of the computed drag coefficient variation compared with the experimental data, Larsson et al. (2015). Up: λ/Lpp=*0.65*, down: λ/Lpp=1.95*

3.2 Amplitudes and Phases of the Heave Motion

Next, the V&V exercise continues in terms of the heave motions. The computed harmonic amplitudes of the heave normalized with the wave amplitude $\zeta=H_S/2$, where H_S is the wave height, and the corresponding harmonic phases are tabulated in Table 3 and plotted in Fig. 7. The heave motion is expressed at the center of gravity when the wave crest is at the forepeak of the hull. The errors for the 0th, 1st and 2nd harmonics of the amplitude vary from 1.42% to 4.60% and from 3.34% to 23.45% for the 3rd and 4th harmonics. The computed errors of the phases vary from 2.51% to 4.74% for the first two harmonics and from 4.03% to 9.08% for the last two. On the contrary, the solutions reported by the participants at the 2015 Tokyo Workshop revealed an averaged level of errors between 10.53% and 66.21% for0th, 1st and 2nd harmonics of the heave amplitude, whereas the average error for the phase was 5.15% and 37.55%. Again, the comparison of the figures reveals a better agreement with the experimental data of the present solution. In spite of the fact that one may conclude that the computation method chosen in this study provide a satisfactory accuracy, the author's opinion is that there is still room for further improvements. From this point of view more studies are necessary to be performed.

Table 3
Harmonic Amplitudes and Harmonic Phases of the Heave Motion (z)

C_1	*z* (λ=3.949 m, *Hs*=62 mm)								
	Amplitude (/ζ)					Phase [rad]			
	0th	1st	2nd	3rd	4th	1st	2nd	3rd	4th
EFD	-0.8092	0.1286	0.0005	0.0012	0.0004	1.5403	2.3131	2.5879	2.6863
CFD	-0.7876	0.1241	0.00049	0.00106	0.00033	1.5793	2.3992	2.6921	2.8811
ε %	2.66%	3.50%	4.60%	10.76%	20.92%	-2.53%	-3.72%	-4.03%	-7.25%
C_5	*z* (λ=11.84 m, *Hs*=196 mm)								
	Amplitude (/ζ)					Phase [rad]			
	0th	1st	2nd	3rd	4th	1st	2nd	3rd	4th
EFD	-0.2005	0.9312	0.0206	0.0013	0.0002	-1.7205	1.3007	1.6636	0.5488
CFD	-0.1949	0.9444	0.0199	0.00131	0.00018	-1.6773	1.239	1.5125	0.5051
ε %	2.79%	-1.42%	3.25%	-3.34%	23.45%	2.51%	4.74%	9.08%	7.97%

Fig. 8 embodies a comparison of the time histories of the computed non-dimensional heave variations and the corresponding measured ones for the two computational scenarios considered. The same conclusions withdrawn when discussing Fig. 6 remain valid here, although a small phase shift seems to take place for the *λ/Lpp*=0.65 computational case.

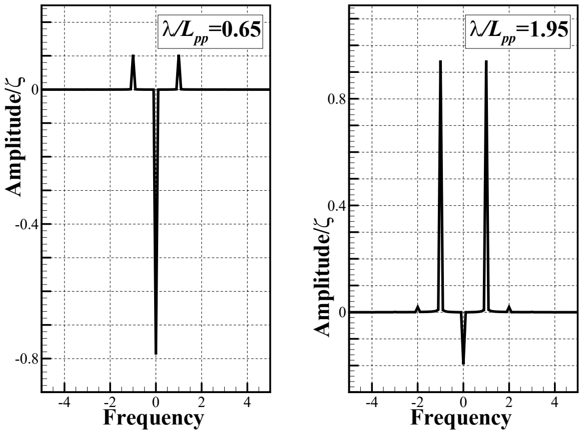

Fig. 7. *Fourier decomposition for the heave amplitude: left: λ/Lpp=0.65; right: λ/Lpp=1.95*

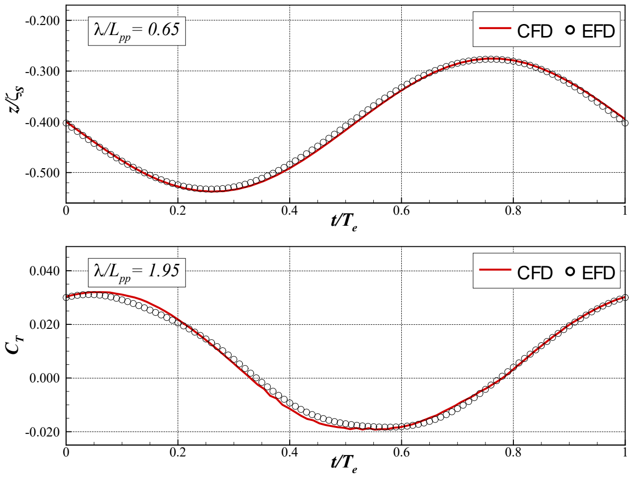

Fig. 8. *Time history of the computed heave/ζ amplitude variation compared with the experimental data, Larsson et al. (2015). Up: λ/Lpp*=0.65, *down: λ/Lpp=1.95*

3.3 Amplitudes and Phases of the Pitch Motion

Similar to the previous two subsections, in the followings another V&V analysis is performed in terms of the θ angle of the pitch motion of the ship hull. The solutions for the same C_0 and C_5 computational cases are tabulated in Table 4, which shows the harmonic amplitudes and phases of the pitch angle. Again, the pitch motion is judged at the center of gravity when the wave crest is at the forepeak of the hull. The amplitude of the pitch angle is normalized in respect to the product of wave magnitude and wave number k, where $k = 2\pi/\lambda$. The tabulated CFD solution values are obtained through the Fourier decomposition as Fig. 9 shows and compared to the corresponding experimental data provided by Larsson et al. (2015). The absolute computational error varies from 2.74% to 32.89% for the amplitude and from 2.34% to 11.94% for the phase. Largest values are again corresponding to the 3rd and 4th harmonics for which the Fourier decomposition provided very small values, subjected to truncations and round-off errors. The report of Stern (2015) on the solutions submitted to the Tokyo Workshop concluded that the absolute average error for the 0th harmonic of the pitch amplitude varied from 9.96% for *λ/Lpp*=0.65 to 16.41% for the *λ/Lpp*=1.95 case, whereas for the 1st harmonic it varied from 38.68% for *λ/Lpp*=0.65 to 6.02% for the *λ/Lpp*=1.95 case. In terms of phase, the reported absolute error for the 1st harmonic varied from 4.31% for *λ/Lpp*=0.65 to 4.68% for the *λ/Lpp*=1.95 case. From all the above figures one may notice that the numerical method proposed in the present paper may lead to solutions whose accuracy is significantly better than those existent in the public domain.

Table 4
Harmonic Amplitudes and Harmonic Phases of the Pitch Angle (θ)

C_1	θ (λ=3.949 m, Hs=62 mm)								
	Amplitude (/$k\zeta$)					Phase [rad]

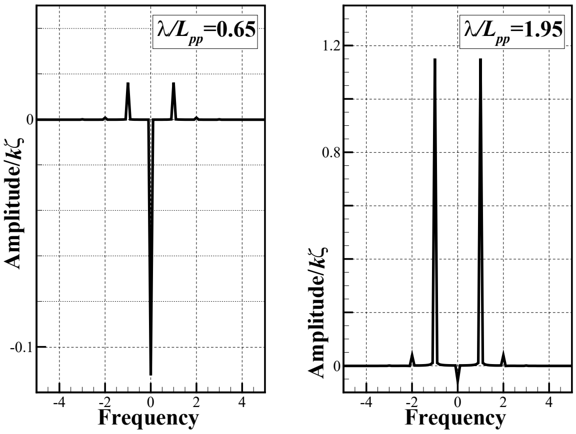
The time history of the computed pitch angle amplitude normalized by $k\zeta$ is depicted in Fig. 10 which bears out a comparison with the corresponding experimental data for the two wave lengths considered everywhere in this paper. Numerical data tabulated in Table 4 are confirmed by the graphs drawn in the figure, which emphasize reveal no significant errors in amplitude or in phase.



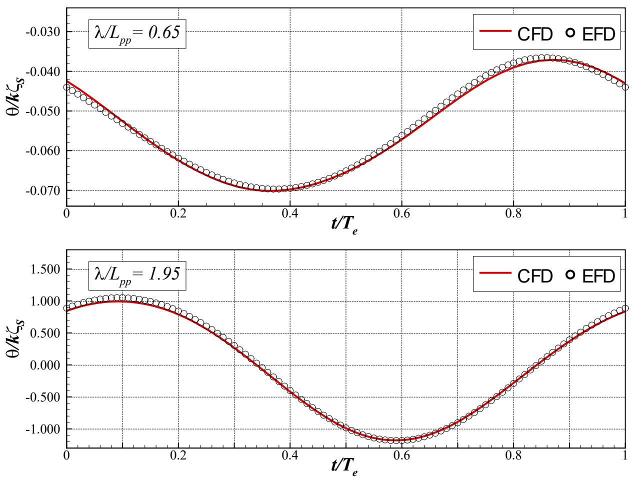


Fig. 9. *Fourier decomposition for the pitch amplitude: left: λ/Lpp=0.65; right: λ/Lpp=1.95*

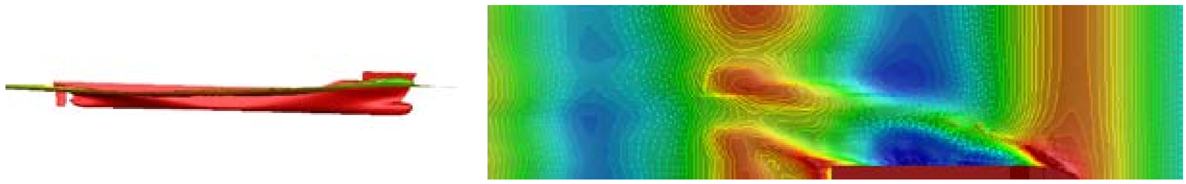
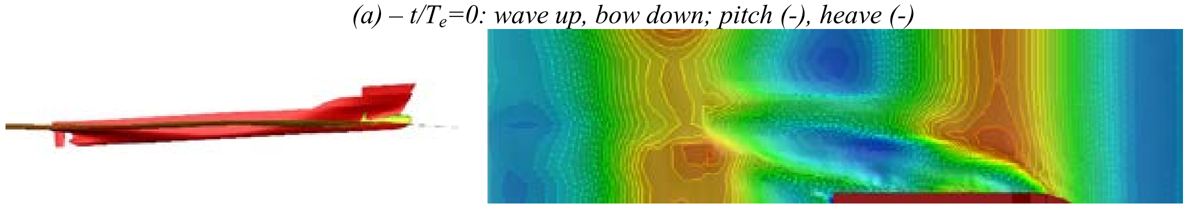
Fig. 10. *Time history of the computed pitch/kζ amplitude variation compared with the experimental data, Larsson et al. (2015). Up: λ/Lpp=*0.65, *down: λ/Lpp=1.95*

3.4 Ship Behavior in Head Waves

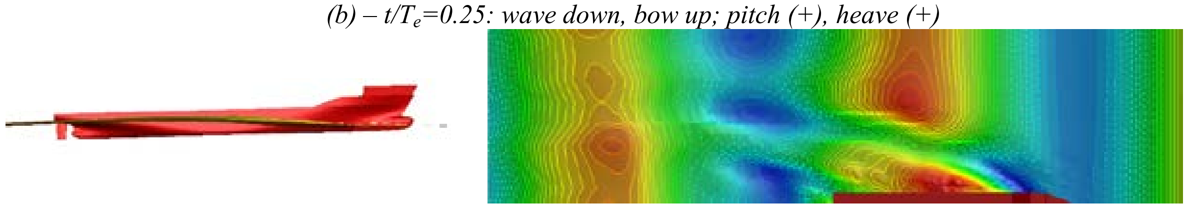
Obviously, the final goal of any numerical simulation concerned with the seakeeping problem is to correctly predict the ship behavior while navigating in waves. Since the previous discussions were only concerned to the V&V, in the followings an example of what such a simulation may be useful for the initial design of a ship hull is presented in Fig. 11, which shows the ship behavior in four different stages of a given navigation scenario. For the sake of diversity, the figure refers to a computational case not discussed so far, namely $\boldsymbol{C_4}$ for which *λ/Lpp=1.37.* The four instances are drawn at t/T_e=0, 0.25, 0.5 and 0.75 respectively. In this particular case t/T_e=0 corresponds to the situation in which the hull bow position corresponds to the top of the wave crest, whereas t/T_e=0.5 corresponds to its trough.



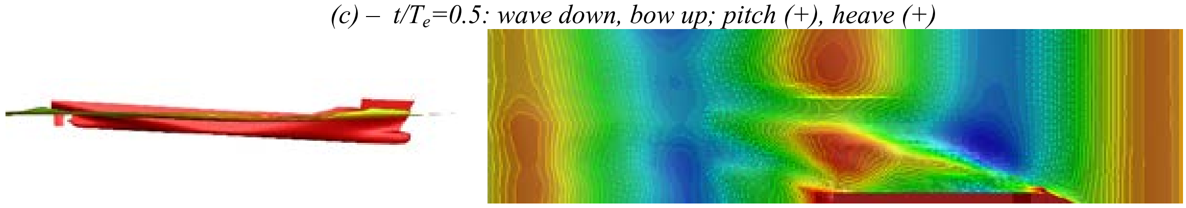
(a) – t/T_e=0: wave up, bow down; pitch (-), heave (-)



(b) – t/T_e=0.25: wave down, bow up; pitch (+), heave (+)



(c) – t/T_e=0.5: wave down, bow up; pitch (+), heave (+)



(d) – t/T_e=0.75: wave up, bow down; pitch (-), heave (-)

Fig. 11. *Ship Motions (left) and Wave Pattern (Right) Over One Full Encounter Period in the Computational Case C4, λ/Lpp=1.37*

The four instances of the ship behavior reveal that when both heave and pitch are negative, i.e. Fig 11 (a) and (d), the forecastle gets flooded and only the bulwark existence prevents the green water to wash the deck. On the contrary, when the heave and pitch are positive, i.e. Fig 11 (b) and (c), the ship bow goes out of the water and associated phenomena such as slamming are expected to happen.

4. Concluding Remarks

A simulation of the 3 DOF seakeeping behavior of the KCS model hull is presented. An extensive V&V check is performed on nine different computations to prove the robustness of the proposed numerical method by means of several comparisons with experimental data. Trial computations revealed that if the discretization is fine enough and the numerical model is suitably adjusted, the computational errors can be kept at a reasonable level. A special treatment for the open boundaries made possible the prevention of any wave reflection. The present study shall be extended to the 6 DOF case to completely edify the ship behavior in real sea.

REDUCTION OF TOXIC EMISSION OF EXHAUST GASES AND FUEL CONSUMPTION OF FISHING BOATS AND VESSEL DIESEL ENGINES

Oleh Klyus[1]

[1] *Maritime University of Szczecin, Poland*

Abstract: The reduction of specific fuel consumption and exhausts toxic emission was possible by implementing preliminary fuel treatment that takes place directly in the fuel injector containing catalytic material. The reduction of the nitric oxides emission level in exhaust gases has been obtained by means of preliminary fuel chemical treatment which is based on the use of heterogeneous catalyst and turbulization canals on the atomizer needle. Turbulizing process as well as homogenization of flowing fuel is carried out at fuel flow in the passages situated on the non-operating needle part, while both crossing passages in the form of left-hand and right-hand thread and crossing grooves on the entire surface of the 2 needles may constitute the form of the said passages. Preliminary fuel treatment results in the average reduction of unit fuel consumption of those engines by 8%, while toxic emission of nitrogen oxides drops by 15%.

Keywords: diesel engines, preliminary fuel treatment.

1. Introduction

The main requirements for modern engines mostly refer to the reduction of toxic compounds emission and firstly this demand refers to nitrogen oxides. However, shipowners primarily pay attention to the issue of operation costs' reduction which are mostly affected by fuel cost. It concerns shipowners of both seagoing ships and smaller vessels. The latter include fishing cutters and fishing boats. It should be underlined that currently the reduction of toxicity of exhaust gases and fuel consumption is carried out by the means of injection systems with electronic control of fuel injection (Common Rail type accumulators) as well as catalytic reactors in exhaust systems. It should be highlighted that simultaneous fuel consumption reduction as well as the level of toxic compounds emission have not been achieved due to the difficulties in engine running optimization under the criteria – engine efficiency (reduction of fuel consumption) increases together with the raise of cycle maximum temperatures, and the high temperature facilitates forming of greater concentration in nitrogen oxides exhaust gases. However, in the fishing vessels that are already in operation, meeting the ecological and economical requirements is not feasible, not only due to the age of the said vessels (Tab. 1 – more than 60% of the Polish fishing vessels are older than 20 years and their age structure is diversified for the particular groups of fishing boats and fishing cutters length) but also due to the modernization problems of the existing engines in terms of installation and control of their operation (Клюс, 2007).

Table 1
Age Structure of Polish fishing Vessels

Years	**<5**	**5-15**	**15-20**	**20-30**	**>30**
Number	54	116	180	175	307

Since the structure of engines for the fishing fleet does not allow for the incorporation of modern common rail injectors and other items reducing the volume of toxic compounds in the exhaust gas, it appears to be advisable to seek for new methods to reduce same. Simultaneously, the operational cost should be reduced mainly by lower fuel consumption. The methods should meet a number of requirements such as simplicity and possibility to be applied in the old generation engines.
The Maritime University in Szczecin conducts research on preliminary fuel treatment on fishing fleet engines and the results that have been obtained so far provide positive results of the direction.

2. Preliminary Fuel Treatment

Let's consider the theoretical grounds for preliminary fuel treatment. As it is known, the first combustion period – self-ignition delay time – has the main impact on the course of thermodynamic effects in internal-combustion engine cylinder (Hejwood, 1988); its shortening leads to lowering of the temperature in the combustion chamber, and hence to mitigation of nitrogen oxides production conditions. From an analysis of various research findings, we can calculate self-ignition delay using this relation:

$$\tau = B \cdot 10^{-2} \sqrt{C} \sqrt{\frac{T_k}{p_k}} \cdot e^{\frac{E_a C^{0,34}}{R T_k}} \tag{1}$$

where:

B, C – constants, T_k – temperature in the combustion chamber when fuel injection starts, p_k – pressure in the combustion chamber when fuel injection starts, E_a - activation energy

[1] Corresponding author: olegklus@o2.pl

According to Heywood [2], the delay time can be determined from this relation:

$$\tau = (0{,}36 + 0{,}22 \cdot c_m) \cdot \exp[E_a (\frac{1}{\bar{R} T_2} - \frac{1}{17{,}19}) \cdot (\frac{21{,}2}{P_2 - 12{,}4})^{0{,}63}] \quad (2)$$

where:

c_m – mean piston speed,

P_2 and T_2 – pressure and temperature in the combustion chamber.

Analyzing the relations defining self-ignition delay time we can see that it depends on such factors as pressure and temperature in the combustion chamber, rotation speed of the shaft and engine kinematics as well as activation energy. It should be noted that in attempts to improve economical and ecological performance of new and used engines there is no practical possibility to change parameters such as pressure or temperature, and basic design features. One possible direction to affect these self-ignition engine parameters is to decrease values of activation energy (Клюс, 2007).

To facilitate overcoming the activation energy, we can deliver more energy to the reaction environment (e.g. by heating) or use a substance that easily reacts with the substrate (low activation energy), and thus formed compound easily converts into a product (also low activation energy). A catalyst is a substance that facilitates a conversion from a reactant into a product and, notably, is not consumed in the reaction. It follows that the presence of a catalyst (e.g. metals of the platinum family) and its contact with fuel before injection into the combustion chamber is desired. Atomization process of petroleum fuels for self-ignition engines occurs in injectors' holes to which fuel is provided through passages injector body and tube channel. The tube channel may be used for preliminary fuel treatment, to be precise, catalytically active material may be applied on the tube channel elements.

The presence of a catalyst in the fuel system has another justification. Chemical properties of fuels used in self-ignition engines can be changed. In paraffin hydrocarbons, the most common group among diesel fuels, paraffin can be dehydrogenated in the presence of a catalysts. In the relevant reactions paraffin hydrocarbons change into olefins C_nH_{2n} and hydrogen molecules are released. Hydrogen, with its high diffusion coefficient, high flammability, high rate of combustion and a wide range of mixture combustibility, reduces self-ignition delay time in the conditions prevailing in the combustion chamber (Hejwood, 1988). The application of catalyst material of platinum group was done using by electro-spark alloying is characterized by a low temperature on the elements of the nozzle needle.

Turbulizing process as well as homogenization of flowing fuel is carried out at fuel flow in the passages situated on the non-operating needle part, while both crossing passages in the form of left-hand and right-hand thread.

Fig. 1.

A photo (a) of a Multi Hole Fuel Injector with Preliminary Fuel Treatment with the Method of Making Turbulizing Passages (b) and Application of Catalyst by Electro-Spark Alloying (c) for Preliminary Fuel Treatment in Multi Hole Injector

3. Laboratory Test

The theoretical assumptions for the preliminary fuel treatment process were verified at a test station where the process of the disintegration of the fuel jet was subject to the analysis.

Particle size distribution in an atomized fuel jet was determined at the first stage of the tests for the proposed method of preliminary fuel treatment. For that purpose, a laser diffraction method was applied with the use of an instrument, made by Malvern, of Sraytec type and of a common rail injector test bench of Bosch EPS200A type (fig. 2). As a research facility, an injector for engine of 359 type equipped with three-hole atomizer was selected. The selection of this injector was justified by the fact that most of fishing vessels is equipped with engines with direct fuel injection and 359 engines constitute their representative part. Apart from the study, the atomized fuel jets were directed to one of the jets in the area of laser beam. Therefore, separating of two remaining jets from that area did not constitute a technical issue. Drawing 5 presents the photographs of the measurement process of particle distribution and the suggested system for fuel discharge from two fuel jets.

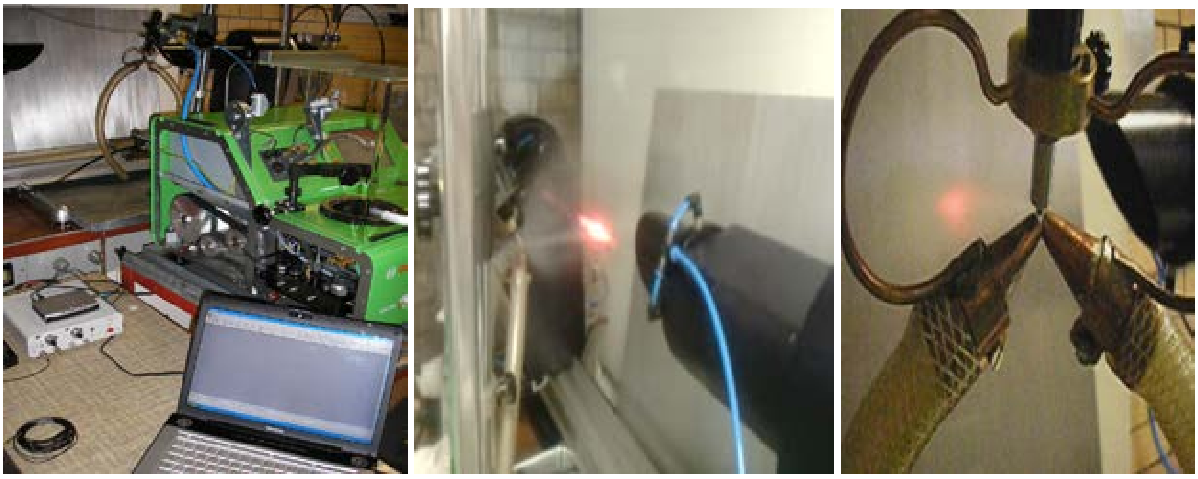

Fig. 2.
Test Stand for Particle Distribution in Atomizer Fuel Jet, Measurement of Particle Distribution in the Laser Beam Area And Separation of Two Remaining Jets From the Laser Beam Area

The laboratory tests results (fig. 3) proved an improvement of fuel atomization characteristics – at the application of primarily treatment the value of a mean Zauter diameter decreased, the number of particles of smaller diameter increased (Клюс, 2007).

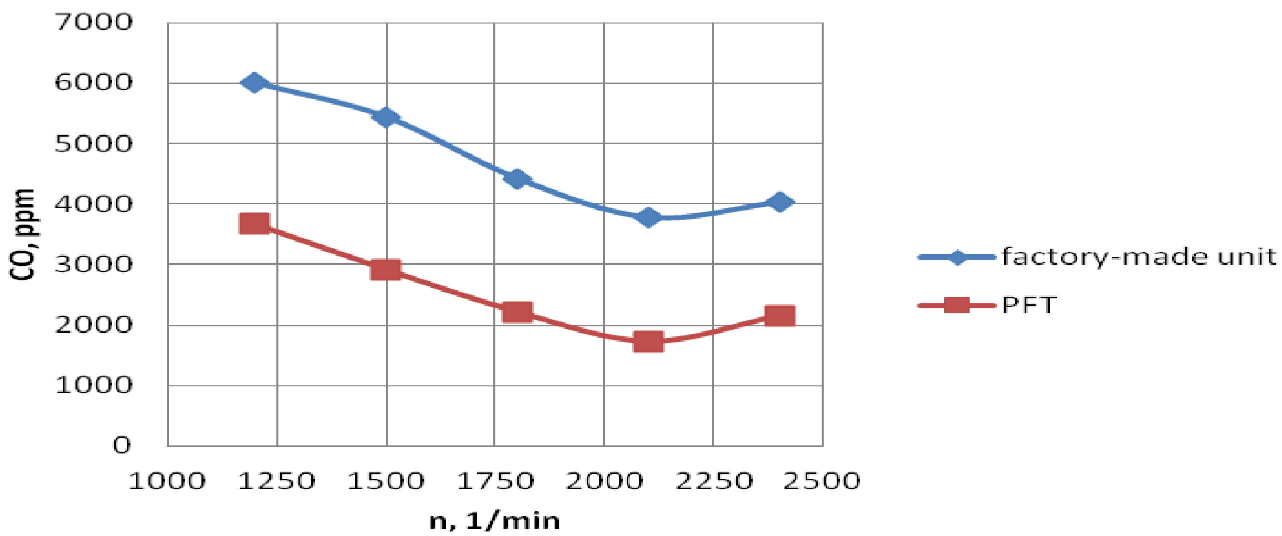

Fig. 8.
Emission Level of Carbon Oxides

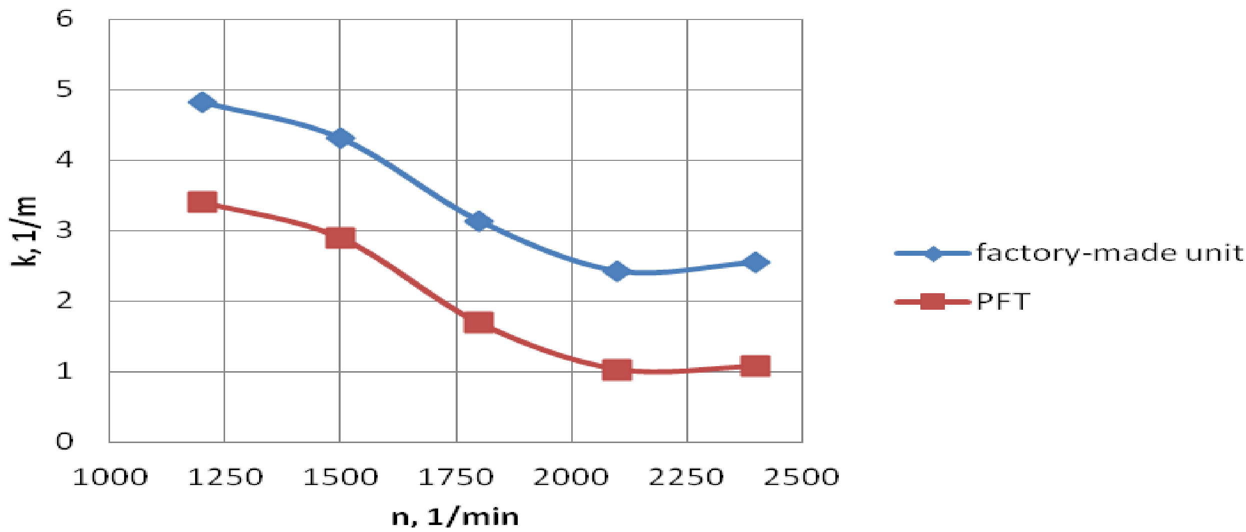

Fig. 9.
Emission Level of Smoke

5. Conclusion

The obtained results prove that there is a room for improvement of economic and ecological parameters of diesel engines when the preliminary fuel treatment process is applied. The treatment process consisting of contacting the catalyst with the fuel directly in the injector body. The technological process of applying the catalyst is simple and easy to perform and the application method proposed in the paper may be implemented at the shipowner premises without any technical problems. A very important aspect that should be highlighted is the low temperature not causing any thermal distortion of the precision elements of the injector. An increased efficiency of the catalyst may be obtained due to the turbulent nature of the fuel flow along the catalyst in the injector. It should be mentioned that making turbulizing passages is a technologically simple task and may be performed at the shipowner premises.

THE ANALYSES OF THE POLISH MARINE CONTAINER TERMINAL MARKET BASED ON PORTER'S MODEL OF FIVE COMPETITIVE FORCES

Robert Marek[1]
[1] *Gdynia Maritime University, Poland*

Abstract: Research has identified many criteria that contribute to evaluating an attractiveness of marine container terminal market in Poland, yet not much is known about how terminal top-managers look at these criteria and how they argue on the factors that contribute to their terminal choice strategy. This study uses Porter's model of five competitive forces to explore those criteria whose determine profitability of the investigated industry. We employ an in-depth methodology that incorporates both quantitative and qualitative methods for an analyzing of substitutes, buyers, suppliers, potential entrants and industry competitors. First, the industry competitors in the marine container terminal market are analyzed. Second, the buyers of the marine container terminal services are described, followed by the suppliers of the terminal infrastructure and superstructure and other services providers. Other competitive forces are the potential entrants and the substitutes they may change current or future situation in the investigated market. The results shall provide some substantial identification where the economic power is placed in the marine container terminal market and how the positions of the different players in the market can be enhanced.

Keywords: marine container terminal operators, container terminals, Porter's model of competitive forces, competition.

1. Introduction

Marine container terminal is the predominant node of transshipment container units. To enhance competitiveness, terminal operators deploy large, fast and partly or fully-automated vehicles to increase terminal yard's capacity and shorten transshipment duration. These capital-intensive investments may further rise barriers for the entry of new terminal operators. In terms of local supply, the marine container terminal market is an oligopolistic market, dominated by one or free terminal operators. The market is also very rate sensitive, as terminal operators need container cargos to fill their every-increasing terminal's capacity. In this sense, even mirror rate reductions might induce customers to shift their shipments to other marine container terminals.

Although attractiveness of sectors has been a subject for research in other industries, the way in which such attractiveness is in the marine container terminal market deserve further investigation. The aim of this study is twofold. First, two research questions were proposed to examine the impact of "the five forces" on attractiveness marine container terminal market. Second, an empirical study, based on attractiveness of MCTM of global marine container terminal operators located in Poland was conducted to validate the hypotheses. The remainder of this article is organized as follows. The next section describes the theoretical background. Research methodologies, including sampling and constructed measurements, are described in detail in subsequent section. The following section presents an empirical study on marine container terminal operators located in Poland. Anyway, conclusions and directions for future research are given in the final section.

2. Theoretical Background

Many research approaches have been proposed and used to evaluate an attractiveness of the market. One such model is the Porter's five forces model (Porter, 1979; pp. 137-145) was introduced as a strategy tool aiming to analyze the immediate competitive environment of individual industries. Having been developed as an industry analysis framework, the five forces model, considers the specific forces that determine competition. The impact of these five factors facilitates the competitiveness and economic potential of an industry.

The developing capabilities and sector's attractiveness are lower, the higher is the barging power of suppliers and customers, the higher is the entry possibilities of newcomers to the sector or just launching new substitution products on the market, and the higher struggle competition among current rivals in the market (Gierszewska and Romanowska, 2003; pp. 99). In the Porter's model, the relations among factors determine level of competition intensity in analysed sector and consequence of its profitability. The relations among "the five forces" are depicted in the Fig. 1

[1] Corresponding author: r.marek@wpit.am.gdynia.pl

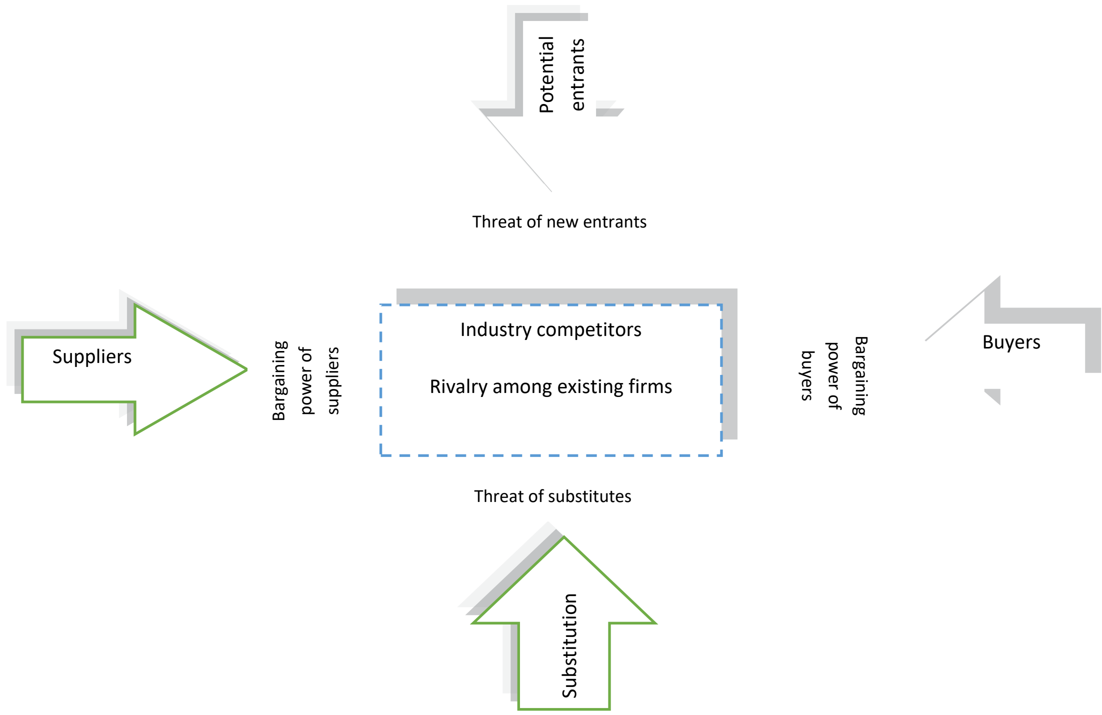

Fig. 1.
M.P. Porter's model of five forces
Source: (Porter, 1985; pp. 5)

The market attractiveness by M. E. Porter (Porter, 1980; pp. 25-40.) is considered to be closely related to the competitive situation in the market, i.e. economy competitiveness of companies and the country. M. E. Porter (Porter, 1980, 25-40), based on the five-forces model, argues that an attractive market is the one in which you can get the maximum profit or benefit, in other words, the more relevant market participants getting on for ideal competition, the less attractive it becomes.

We have in mind, that the model is still giving a critical judgment of some researchers (McGahan, 2000; pp. 1-16; Whittington, 2009; Van den Berghe and Verweire, 2000; Malhotra and Gupta, 2001; Burton, 1995; Ul-Haq, 2005; Brandenburger and Nalebuff, 1995; pp. 57-71; Yoffie and Kwak, 2006; pp. 88-98; Christensen, 2001; pp. 105-109; Grundy, 2006; pp. 213-229; Karagiannopoulos, Georgopoulos and Nikolopoulos, 2005; pp. 66-76; Siaw and Yu, 2004; pp. 514-523). According to (Obłój, 2007, 256-257) these criticism comes from main four limitation of using this model.

Firstly, the model derives from industry economy mainstream, that's why the model concentrates on closer environment of the company – branch. Unfortunately, it is a very limited perspective of analysis so it should be completed with: political, social and technological trends and events.

Secondly, the hard measured sounds which comes from the used model, though essential may be passed over in decision-making. Therefore, this model shall be completed with quality elements, which are not used in Porter's model.

Thirdly, this model analysis bargain powers of suppliers, customers; threats of potential newcomers, substitute's products, and finally rivalry of current competitors in the industry. The military language and the way of analyze comes from the economically concept of cut-throat competition. In some sectors, such competition concepts still exist but current situation in the global economy needs more sophisticated analysis. Once, the competitors entered into the strategic alliances and some others forms of cooperation and suppliers and customers has become strategic partners for some companies, the Porter's model turns into outdated and must be completed with cooperation dimension.

Fourthly, as indicated consulting and some results of researches not all analyzed forces are equally essential. For example, P. Ghewamat (Ghewamat, 1999; pp. 34-35) pays attention that barging powers of suppliers and substitution products maybe ignore in this model because they are not statistically significant in explaining strategical behavior of companies and profitability of branch. To the similar conclusions have come M. Sosnowski (Sosnowski and Obłój, 2004; pp. 65-67). According to his analysis, Polish managers mainly concentrates on its competitors and customers but they take the less notice of potential new entrants (entry barriers) and substitution threats.

The aim of this paper is to assessment on the potentiality of marine container terminal market. The fundamental question, which we would like to receive in this section is: Where is the economic power marine container terminals market? By economic power we mean: the potential to generate profits from invested capital in the long-run.

2. Methodology

2.1. Data Collection and Measures

The respondents for this empirical study were the all marine container terminal operators located in Poland. Questionnaires were personally presented to the respondents and discussed in detail if it has been needed. A total of 5 of 5 questionnaires were returned accounting for an effective rate of 100 per cent. The respondents have belonged to top-managers of their companies. The study was conducted in the marine container terminal operators in January – March 2018.

During the construction of the analysis's scheme, assuming that, the respondents of the research well-known M.E. Porter's concept "five competitive forces". In the proposed version of the approach, it is necessary to analyses bargaining power of suppliers, customers; the treats of substitutions, new entrants as well as industry competitors. In an attempt to reflect the wide range of competitive drivers. The competitive drivers were taken from various sources including writing papers and news reports and spoken opinions from scholars and seaports community.

Generally, industry's assessment by M. P. Porter's model the five forces is conducting by description form. It means that every identified factor is studied in relation to its impact at the given one competition force as well as performing a general assessment of every forces individually and finally assess of current or perspective situation in the investigated industry. Such description methodology is proposed by the M.E. Porter. The author has determined the factors which shall be take in the study of the industry and their influence at the given forces but he did not propose any assessment's method and draw the conclusions (Penc-Pietrzak, 2003; pp. 58; Giereszewska and Romanowska, 2003; pp. 316-320). The evaluation of every individual competitive forces is not very useful. In order to receive more detailed on assessment of competitiveness of the analyzed market the every individual factor was valued by attributing point using a five-point scale, anchored by 5 = 'high favorable' and 1 = 'high unfavorable'. Every factor was assessed by respondents (senior managers) and then it was calculated an arithmetic mean for every factor. This methodology was more developed by indication an attributed weights which scale ranges from 1 to 3 points. This attributed weights indicated by respondents show which factors are more or less important for the investigated industry. In the same manner as formerly, the attributed weights for every factor was calculated on arithmetical mean base. Then all attributed weights (in Table's columns) were summarized for every competitive force and received result was attributed value 100 per cent. Afterwards, it was calculated the share of every individual attributed weigh in the received result from the summarized of the arithmetical average contained in column. In the research all respondents belonged to top managers of the marine container terminal operators. This study sought answer for the following research questions:

- Q1: What are the most important competition drivers for MCTOs?
- Q2: Where is the economic power placed in the marine container terminal market?

3. Results and Analysis

This section presents the findings from all marine container terminal operators' responses. A logical question has been asked at the beginning of the research: where currently the economic power is placed in the marine container terminal market? Identification of main criteria and them weights in the Porter's model five forces for the marine container terminal operators were shown in the below tables. In this study, all competitive forces were separately evaluated.

Threat of new entrants; the threat of new entrants is the possibility that new marine container terminal operators may enter the industry. New entrants bring a desire to gain "proper" market share and often have significant resources. The most important criteria of new entrants treat are shown in Table 1. The most important threat of newcomers comes directly from two main drivers e.g. sector attractiveness and high of entry barriers. Currently, the container terminal market is characterized by relatively high return of equity and high market growth rate and those both criteria may encourage new terminal operators at the Polish market. Fortunately for the current market competitors there are high entry barriers which protect the "old" competitors. However, when newcomers entered into the investigated industry there is no large possibilities of repression from the all current marine container terminal operators.

Table 1
Threat of newcomers into the sector

	Evaluation criteria	Average weight the range from 1 to 3 points (1)	Rating threat of newcomers in the industry in the industry (the range from 1 – high unfavourable to 5 – high favourable points). (2)	The average weighted rating scale (1)x(2)=
1.	High of entry barriers	0,36	4,4	1,58
2.	Sector attractiveness	0,38	4,8	1,85
3.	Possibilities of repression from the current terminal operators	0,26	2,4	0,62
4.	Sum the weighted rating scale	1,00		**4,04**

Source: Own elaboration.

As mentioned before, the high entry barriers may protect old competition order in the marine container terminal market. Therefore, it is remarkably important to assess the degree of entry barriers for the industry. According to respondents, the current marine container terminal operators are pretty well protect against potential new entrants. They indicated the most important criteria of barriers entry as follows: capital required (0,57), access to distribution channels (0,57), localization (0,55), economy of scale (0,53), customers loyalty (0,37), broaden range of terminal' services provided by terminal operator (0,34), UE and State law regulations (0,31) (Table 2). As we can see from the table, according to top managers such factors as access to technology (0,20), brand identity (0,18) and switching costs (0,15) are much less important entry barriers. The capital required is very high when newcomers are going to do major investments to enter this industry. This industry is not an easy business to start because it is capital intensive. The top-managers indicate that very important entry barrier is access to distribution channels which mean in this paper access to hinterland. Currently, the marine container terminal operators want to be closer to market-orientated operations, shipper preferences and terminal performance would play a vital role in setting up the high entry barrier. Localization is crucial important for newcomers because the "first best localization" is occupied by current competing terminal operators. For example, the marine container terminals located in seaports Gdynia or Szczecin-Świnoujście have worst localization then Deepwater Terminal Gdansk located in Gdansk seaport. Therefore, to the DCT may call the largest container vessels as can enter into the Baltic Sea, so this terminal transforms into the hub terminal meanwhile others terminals become the feeder terminals. However, when seaport Authority develop its infrastructure then it appears new localization for potential newcomers. In this way, the localization barrier may also become unimportant. Gdansk Port Authority, for example, has been building outer seaport with large terminal's infrastructure which allow the newcomers to enter the business and to take into concession "the first best" location which allows to service the largest container vessels. The terminal operators form seaports Gdynia and Szczecin-Świnoujście also may take an opportunity from this investment. Therefore, the Gdynia Port Authority undertook similar investment to keep the current terminal operators in its area. It is known that a un (loading) process for a terminal's services exhibits economies of scale over the range of output when average cost declines over that range. So, the economy of scale compels the potential newcomers to enter into the terminal market on a large or small scale. In the first case, the current MCTOs may react very sharply on the new entrant though it is very unlikely (see investigated results on industry competitors). In the second case, the new entrant will bear a high costs and very likely will withdraw from the market. The customer loyalty, it is next important factor meaningfully restrictive entrance of newcomers into the market. The top-managers know that possesses the loyal customers make up additional asset of their competition predominance over new entrants because new terminal operators will have to spend a lot of money to take a new and existing customers. In spite of that knowledge, the terminal operators have a lot of problems with building a strong relationships with customers (see – bargaining power of customers). Broad range of service assortment provided by terminal operator decides on its strategic position strengthened. The extension of terminal service assortment is twofold. The first, marine container terminal operators broaden and improve its core and additional service assortment. The second, for example, marine container terminal operators located in Gdynia seaport, heavy cargo units have been added. In this way, the terminal operators wants to build strong loyalty with existing customers and to gain the new ones for new activity. The UE and state law regulations may install entry barriers. The UE or state government may impose on marine container terminal operators new solutions concerning on getting rid of bottleneck in terminals and their hinterland due to inadequate infrastructure or terminal's services. In this way, the terminal operators may need to bear extra costs on congestion, or just reduction emission in accordance with green initiatives (Klopott and Miklińska, 2017; pp. 523-536; Klopott and Miklińska, 2016; pp. 639-644). Access to terminal technology is not very important entry barrier because this technology is well-known by the market participants. Similarly, the switching costs are not regards as important for entry barrier by respondents because a change of supplier is not so high, especially, if it concerns the terminal equipment. Although it can be meet with opposite opinion (Wiegmans, Masurel and Nijkamp, 1999; pp. 120). Brand identity regards to perceive quality and value terminal's services by customers. Unfortunately, the top-managers indicate that this factor is the less important as an entry barrier because the customers follow the low price or just sea lane offered by container shipping company in the marine container terminal. Therefore, to get the success the new entrants have to provide terminal's services at a low price and/or high quality to establish their market value.

Table 2
Entry barriers

Source: Own elaboration.

Bargaining power of suppliers indicates on how dominant suppliers can reduce marine terminal operators power in negotiation for a renting a seaport's infrastructure or purchasing terminal facilities (terminal's vehicles – cranes and so on) and their profitability. Increased supplier power is determined by a number of factors. According to respondents opinions, the bargaining power of suppliers in the investigated market comes from the following factors: quality of final terminal's service depends on quality of supplier's products (0,79); switching costs (0,60); concentration power (0,51); unrepeatability quality of services provided by suppliers (0,51); sharp struggle competition in the supplier's sector (0,44) (see table 3). When terminal's facilities used by marine terminal operator are significantly influencing on the end quality terminal's services then the supplier will have to negotiation better terms of delivery. The top-managers also indicate that they will also face a significant switching cost if they decide to change terminal's supplier. Furthermore, concentration of power in the sector includes a relatively small number of suppliers because they often offer an unrepeatable quality of terminal's infra- and superstructure as well as services.

Table 3
Bargaining power of suppliers

	Evaluation criteria	Average weight the range from 1 to 3 points (1)	Rating bargaining power of suppliers in the industry (the range from 1 – high unfavourable to 5 – high favourable points). (2)	The average weighted rating scale (1)x(2)=
1.	Concentration in the sector	0,13	3,8	0,51
2.	Quality of final terminal's service depends on quality of supplier's service	0,17	4,6	0,79
3.	unrepeatability quality of services provided by suppliers	0,16	3,2	0,51
4.	Facility and lower switching costs of suppliers	0,16	3,8	0,60

7.	Sharp struggle competition in the supplier's sector	0,15	3	0,44
8.	Possibilities integration forward	0,06	1,2	0,07
9.	Sum the weighted rating scale	1,00		**3,26**

Source: Own elaboration.

The sharp struggle competition of the terminal's suppliers is meaningfully differential. A huge power of supplier has a provider of marine container terminal's infrastructure – Port Authority because of one's local or regional monopolistic position, (see table 4). In turn, in the superstructure suppliers market, there is a strong struggle competition in spite of a limited number of suppliers existing within investigated market. Moreover, some respondents pay attention that lastly increased power of well-qualified blue-collar workers suppliers in the marine container terminals. Temporarily, this problem has been solved by employment of workers from the Ukraine.

Source: Own elaboration.

Anyway, this poses challenges for marine container terminal operators as they will be highly dependent to renting, leasing or just buying from these various types of suppliers. In the analyzed market, there is a very low power of suppliers to integrate forward meaning so there are the lack of danger to cut out marine terminal operators and reach end customers directly.

Here we will pay attention to **bargaining power of customers** of marine container terminal market. The strength of this competitive force depends on several criteria that determine customers' power. The position of the customer becomes stronger if the marine container terminal operator bears high investment costs and if the level of marine container terminal's capacity utilization is low (Wiegmans, Masurel and Nijkamp, 1999; pp. 105-128.). The bargaining power of buyers is fairly high (see Table 5). According to respondents opinions, the bargaining power of customers in the analyzed market comes from the following factors: facility and lower switching costs of suppliers (0,63); customer's concentration (0,61); quality of final terminal services depends on quality of suppliers' products and services (0,57); sharp struggle competition in the customer's sector (0,56); large share of supplier in creation of terminal's operator profit (0,47); possibilities entering of suppliers in the terminal's market (0,32); possibilities integration forward (0,32); unrepeatability quality of services provided by customers (0,30) (see table 5). In the analyzed market, the most crucial factor of buyer are switching costs because customer may easy to switch one terminal operator to another as their terminal's product offerings are not highly differentiated. Obviously, the switching costs are different for two main groups of customers: liner shipping companies and forwarders. Usually, the shipping companies conclude a trade agreement with marine container terminal operator for short or medium term. It this situation, the switching costs are comparatively high. From the other side, the most forwarders have no any signed trade contracts with terminal's operator so the switching costs for them are very low. Therefore, the forwarders are the most disloyal customer group for the marine container terminal operators because their gain a low profit margin. When the marine container terminal operator rises the price for terminal's services then the forwarders moves its activity to other terminal operator, if provided it is just and feasible. The concentration of power also is very important factor, especially if concerns to liner shipping companies which entered into global terminal market (Notteboom and Rodrigue, 2012; pp. 271; Marek, 2016; pp. 11-37). The members of liner shipping alliances have a stronger negotiation power compare to MCTO. The forwarders are acting in the perfect competition in the container market so by the definition they have a weak negotiation power then the MCTO. That's why, the forwarders have to adopt to requirements and way of work imposed by terminal operator. The quality of terminal's services influence directly on quality of services provided by liner shipping companies and forwarders, it also means, that MCTO has a strong negotiation power. Sharp struggle competition in the customer's sector indicates on low level of concentration power. Large share of customers in creation of terminal's operator profit strengthens bargaining power of the customers albeit the customers will put pressure terminal's operator on price cutting. To our knowledge, the keeping customers should be a paramount concern of every marine container terminal operator. Therefore, they shall determine what customers need in terms of terminal's services and deliver upon those needs in efficient manner.

Table 5
Bargaining power of customers

	Evaluation criteria	**Average weight the range from 1 to 3 points (1)**	**Rating bargaining power of customers (the range from 1 – high unfavourable to 5 – high favourable points). (2)**	**The average weighted rating scale (1)x(2)=**
1.	Customers concentration	0,13	4,6	0,61
2.	Quality of final terminal's service depends on quality of supplier's service	0,14	4	0,57
3.	Unrepeatability quality of services provided by customers	0,10	3,2	0,30
4.	Facility and lower switching costs of suppliers	0,14	4,4	0,63
5.	Large share of supplier in creation of terminal's operator profit	0,12	3,8	0,47
6.	Possibilities entering of suppliers into the terminal's market	0,11	2,8	0,32
7.	Sharp struggle competition in the customers' sector	0,13	4,2	0,56
8.	Possibilities integration forward	0,11	2,8	0,32
9.	Sum the weighted rating scale	1,00		**3,79**

Source: Own elaboration.

The lower prices for terminal's services the customer's lower costs and higher profits. When terminal's services customers have the ability to provide the same services themselves instead of buying it from MCTO, their power is also significant. The possibilities entering of customers in the terminal's market and possibilities backward integration depends on the type of customers. For example, liner shipping companies have bought some marine container terminals to improve its core business activity. Finally, the unrepeatability quality of services provided by customers are the least important because the services are relatively easy to copy.

Threat of substitutes. The threat of substitutes, generally, in the analyzed market is not so important for top-managers. In this market, substitutes are differentiated from the core terminal's services that the main competitors within the market offer. The threat of substitutes is fairly low (see Table 6). According to respondent's opinions, the threat of substitutes in the analyzed market comes from the following factors: sector attractiveness (1,52); sector age (1,17); speed of technology change (0,88). The higher attractiveness of the sector the higher threats of new terminal's services or substitutes. For example, high demand for containers movement developed in-land container terminals network and new multimodal connection called Silk Route. It means that, forwarder may sent container by sea transport using marine container terminal or alternatively may sent container by multimodal rail transport using in-land container terminals. In this connection, the multimodal rail transport becomes a substitute for sea transport and in-land container terminal's services becomes a substitute for marine container terminal's services.

Table 6
Threat of substitution services

	Evaluation criteria	**Average weight the range from 1 to 3 points**	**Rating threat of substitutes terminal's services (the range from 1 – high unfavourable to 5 – high favourable**	**The average weighted rating scale**

		(1)	points). (2)	(1)x(2)=
1.	Sector attractiveness	0,38	4	1,52
2.	Sector age	0,34	3,4	1,17
3.	Speed of technology change	0,28	3,2	0,88
4.	Sum the weighted rating scale	1,00		**3,57**

Source: Own elaboration.

In this way, the existing customers may switch the new transport connection and create a negative impact on the analyzed industry's market share and its profitability. The wandering answer of respondents concern the final factor. According the top managers, there is not large treats of substitute by increase speed of technology change because the changes in terminal's technology are longer than 5 years.

We will now discuss the last competitive force from Porter's model - **rivalry among competitors**. This force describes how the other four powers interrelate and shape the structure of competition in the analyzed industry. There are certain factors by which competitive rivalry is determine in the market. The respondents determined the main competition factors in the industry as follows: number of competitors (1,61); share structure in the sector (1,54); customer's strategy (0,91) (see Table 7). The analyzed market currently compete only 5 marine container terminal operators. In Poland, there are three main seaports, i.e. Gdynia, Gdansk (located in Gdansk Bay, on the southern Baltic) and the port complex Szczecin-Świnoujście situated in the western part of Poland's coastal area. The Gdynia seaport has agreements three marine container terminals operators: Baltic Container Terminal Ltd. (belonging to ICTSI – International Container Terminal Services Inc. – Manila), Gdynia Container Terminal Inc. (belonging to Hutchinson Port Holding – Hong Kong) and OT Logistics Group Inc. (belonging to Polish Capital – with a diversified commodity portfolio – included container operations). The Port of Gdansk included the following container terminal: Deepwater Container Terminal Inc. (owned by The Macquarie Pension Funds). The port complex Szczecin-Świnoujście, meanwhile, embraces two container terminals, and that are OT Port Świonujście Inc. (owned by OT Logistic Group) and DB Port Szczecin Ltd.

Table 7
The competition struggle inside industry

	Evaluation criteria	**Average weight the range from 1 to 3 points** **(1)**	**Rating competition struggle inside industry (the range from 1 – high unfavourable to 5 – high favourable points).** **(2)**	**The average weighted rating scale** **(1)x(2)=**
1.	Numbers of competitors	0,37	4,4	1,61
2.	Share structure in the sector	0,37	4,2	1,54
3.	Customer's strategies	0,27	3,4	0,91
4.	Sum the weighted rating scale	1,00		**4,06**

Source: Own elaboration.

The share structure of the industry is diverse. The DCT has a predominant position on the Polish marine container terminal market because of its localization. The other two competing terminals located in seaport Gdynia (BCT and GCT) are approximately the same size so the rivalry among them is highly intense. The remaining three terminal operators are quietly small size. In spite of the industry growth rate is high, rivalry is still very intense because terminal operators see chances or just feel pressure to improve their position. Additionally, there is not significant differentiation between the terminal's services offerings of individual marine container terminal operators, the level of rivalry is also intense. Customer's strategy offered by individual terminal operators are diversified. The respondents pay attention that they compete against each other by: price (price war) and quality of terminal's services; speed of terminal's services; effectiveness of used resources, additional terminal's services offerings; linking customers with terminal operator by offering loyalty package; transport service connection offerings. Only one top-manager indicates that the operator implements low cost strategy. Other four respondents declare that implement differentiation strategy. By the differentiation strategy terminal operators decide to diversify the number of features of a terminal's services to provide more choices to the consumer. Terminal operators make this decision after conducting sufficient market research to determine the needs and desires of their customers. To make a profit, the cost of adding a new feature must be affordable and there must be a reasonable expectation that customers will pay a higher price for the core or additional terminal's services or both. In this way, the terminal operator has created a differentiation that provides a competitive advantage.

Anyway, the existence of high **exit barriers** in the industry, if a marine container terminal operator wishes to leave the industry will also trigger high rivalry. The respondents indicate that the most important exist barriers for the industry are: assets specialization (1,35) and high fixed costs of exit (0,86) (see Table 8). The high degree of specialization of assets means that the terminal operator may have a great problem with selling them for a good market price. The close competitors will try to purchase the assets by minimum price. The high fixed costs are close connected with signed trade contracts with infra- and superstructure providers. The large fine penalty of breaking off the trade contracts is important exit barrier of terminal operator from the industry.

Table 8
Exit barriers

	Evaluation criteria	**Average weight the range from 1 to 3 points (1)**	**Rating exit barriers in the industry (the range from 1 – high unfavourable to 5 – high favourable points). (2)**	**The average weighted rating scale (1)x(2)=**
1.	Assets specialisation	0,29	4,6	1,35
2.	High fixed costs of exit from the sector	0,22	4	0,86
3.	Psychological barriers	0,10	1,8	0,18
4.	Strategic barriers	0,16	2,2	0,35
5.	Political barriers	0,12	1,6	0,19
6.	Social barriers	0,12	1,6	0,19
7.	Sum the weighted rating scale	1	15,8	**3,11**

Source: Own elaboration.

The other factors of exit barriers such as: strategic, political and social barriers are not important for terminal operators in spite of pushing to corporate social responsibility concept. It must be notice that by strategic barrier means big significance of the local market for headquarters of terminal operator. The intensity of competitive rivalry in the industry is extremely high. All marine container terminal operators face intense competition and they are competing with each other over price, core and additional terminal's services and promotions intermittently. It should be noticed that entry barriers are much higher than exist barriers, so it means that, current terminal operators are well protecting against potential new entrants in to the marine container terminal market.

4. Conclusions

Not all of these forces are equally important when assessing the overall attractiveness of marine container terminal industry in Poland. In the terminal market entry barriers are relatively high and exit barriers relatively low. This implicates that profits in the marine container terminal market are high and not so risky. This situation directly comes from a high industry growth rate. Furthermore, the terminal operators make new investments into increase their terminal capacity. This deteriorates the market because all existing terminal operators make an efforts to fill their terminal capacity and this runs to competition intense. The current importance of the actual competitive forces of the groups of actors in the terminal market was visually depicted in Fig. 2.

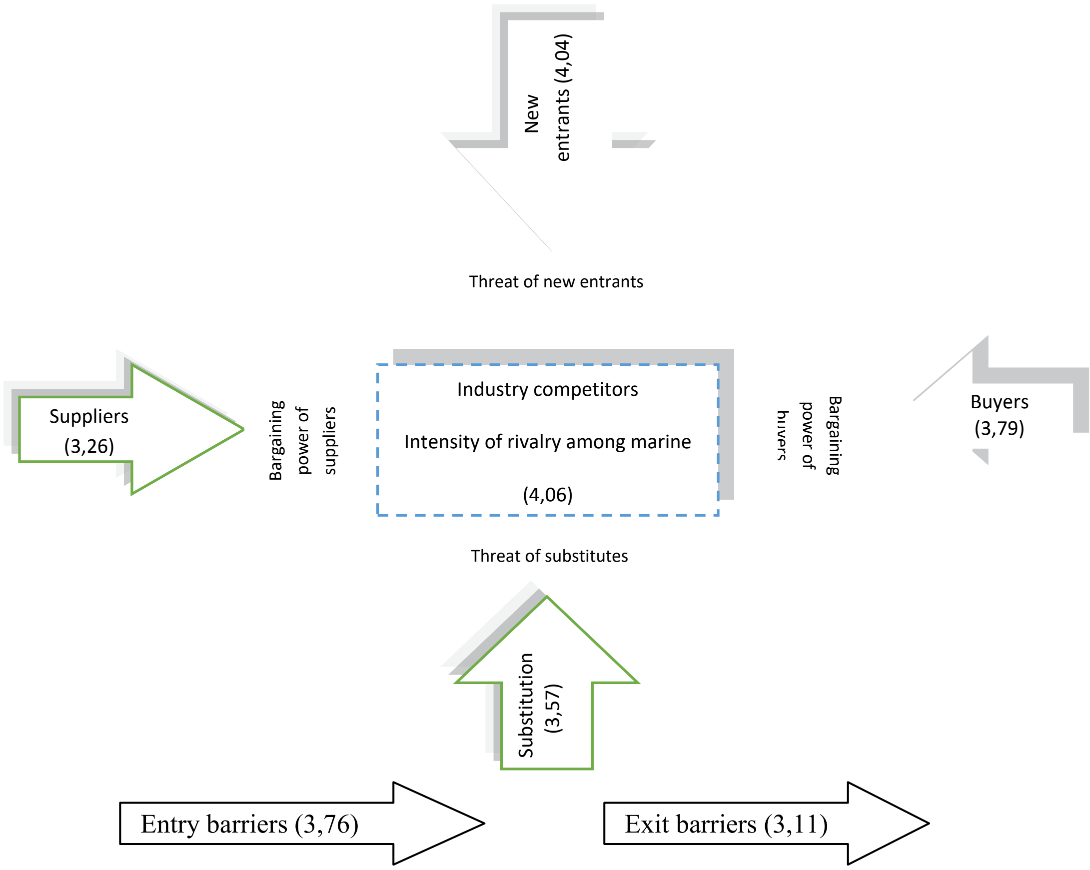

Fig. 2.
Investigated results of competitiveness marine container terminal market based on M. Porter's model of five forces
Source: own elaboration.

Figure 2 shows our syntheses that the competitive strength of the industry competitors is relatively weak, and therefore there is considerable room for improvement. The suppliers of marine container terminal infrastructure and the customers of the terminal services have especially strong economic power. The strength of their economic power obviously restricts the profitability of industry competitors. The threat of potential entrants and the threat of substitutes further decreases the economic power of industry competitors.
Future research should lead to consider the prospects for marine container terminal operators in the close future. Moreover, future efforts should aim at further identifying best practice in competitiveness assessment and should contribute to developing a more general framework for successful model implementation. Furthermore, future research should investigate the measurement of the marine container terminal service performance as a starting point for improving the core and additional terminal service assortment.

Abstract: European transport market has changed significally in the last two decades. The establishment of production facilities in the countries of Central and Eastern Europe has made cargo flows from Adriatic ports growing, as their location enables shorter transit times to the hinterland countries. As the strategic goal of Adriatic ports is to become one of the most important gateway regions in Europe, traffic growth represents a great financial and development opportunity for them, but at the same time, it has a significant impact on environmental pollution and the quality of life in the surrounding area. To support European ports development in an environmental friendly way, several studies and environmental priorities has been published within the EU. The port of Koper as the leading container and car carrying port of the North Adriatic area is trying to follow those directions. Its goal is to increase traffic along with the concern for the environment, so their future investments will be part of the strategy to become a green port. The paper therefore presents EU priorities that the North Adriatic ports, especially Koper, will have to implement, insofar as they want to acquire the status of green port.

Keywords: green port concept, environmental friendly seaports, sustainable development, port of Koper.

1. Introduction

The importance of the ports for the European economy are well known, as they represent one of the most important nodes in the transportation of goods. In the last ten years, after the global crises and with the expansion of world trade, especially world container traffic grew substantially. This rapid economic growth pushed ports to follow the trends as are new size of ships (trade growth and economies of scale are main reason for the increasing sizes of ships), higher productivity of cranes, shorter time of stay in ports... In these new conditions, ports need to modernize port facilities and include new technologies if they do not want to loss cargo, maintain the throughput level and competitive position on the market. The new investment in the technology and modernization must be also in accordance with new standards regarding "green" perspective. Green port is a port in which the port authority and port users pro-actively and responsibly develop and operate, based on an economic green growth strategy (PIANC, 2014). In line with the concept of the green growth, sustainable port initiatives has been developed by combining sustainable economic growth with environmental measures for an improved cost-benefit strategy (Lam and Notteboom, 2012).

Green port strategy and green port development are new trends in the world as ports are bigger and bigger and port development can have a negative impact on the surrounding area. There are researches in the field of ecological issues in ports and port management policies in relation to green port development (Peris-Mora et al., 2005; Darbra et al., 2009, Nebot et al., 2017). The main conclusions shows that there is a need for innovative solutions for sustainable port development.

In EU project Portopia (European Port Industry Sustainability Report 2016) ten environmental priorities of the ports have been selected. These are air quality, energy consumption, relation with the local community, garbage / port waste, ship waste, port development (land related), water quality, dust and dredging operations. The selection model of the priorities was obtained from 91 EU ports that participated in the study. The same research was performed also in the year 2006 and the study exposes that situation changed dramatically. Twenty years ago the problem of air quality was not observed as one of the crucial port's problems. At that time, the biggest problem was the port development (especially at the waterside). The project highlights that over all this time the issues of port development (landside), dredging and dust were always present, but not in the same order of priorities.

Nowadays, the problem of the air quality is in the top of environment priorities of the ports, especially due to the ships. Lam and Noteboom (2014) expose that ships are a major source of air pollutants such as CO_2, SO_2, NO_x and PM_{10}. Anyhow, Merico et al. (2016) state that harbour logistic has a relevant role in determining the total impact of shipping on air quality of the nearby coastal areas. According to the IMO (IMO 2014) international shipping contributes approximately 2,4% of global GHG (green house gas) emissions and it will increase in the future. Gibbs (2014) present possible actions for reducing emissions with the reduction of the ship speed (Green flag programme), green ship promotion and on shore power supply. The field of shore power supply and energy management in seaports is becoming of special importance (Accairo et al., 2014; Zis, 2014, Copolla et al., 2016).

According to study made by OECD in 2011 Environmental impact of international shipping – the role of the ports (OECD, 2011), shipping has a great impact to the ports and to the ports vicinity. The study highlights following areas of greater impacts: the noise and gases from ship engines and noise from cranes used for loading and unloading, dust when handling with coal and grain, and road and rail traffic to and from the port. They identify main environmental impact of ports as problems of port activities, problems at the sea done by ships calling the port and the problems of emissions from transport networks serving the port hinterland. Similar impacts were indicated by Lam and Notteboom (2012). They range them in three main groups: air pollution, water pollution and the maintenance and upgrading of port infrastructure, causing a high impact on marine ecosystems due to dredging and civil works.

[1] Corresponding author: elen.twrdy@fpp.uni-lj.si

There is a strong need of the common policy instruments for managing presented environmental impacts. The sustainability is the future, thus ports must work in accordance with this trend. This is valid also for NA ports. In the paper, we present how Port of Koper, as one of the NA ports, deals with this issues and how they define measures for the establishment of green port.

2. Ports in the North Adriatic

World seaborne trade volumes reached 10.3 billion tons in 2016, and reached an expansion of 2.6 % over the previous year. This is still below the average of 3 % recorded over the past four decades. Anyhow, the projections for the 2022 show that volume will grow with an estimated compound annual growth rate of 3.2 %. Volumes are set to expand across all segments; the fastest growth is expected in the segment of containerized trade and major dry bulk commodities (UNCTAD, 2017). As maritime transport produce around 1 billion tons of CO_2 annually and is responsible for about 2.5 per cent of global greenhouse gas emissions from fuel combustion, the expected growth could be an environmental problem.
Maritime transport on the Europe-Asia-Europe route has been increasing constantly over the last decade. The northern European ports have had the leading role in this trade making a large number of European hinterland countries' maritime supply dependent of them. The importance of North Adriatic (NA) is increasing in last decade, but ports of Koper, Rijeka, Trieste, Venice and Ravenna are still medium size or smaller ports in the EU port system. These ports became important player in the EU transport market due to their location. They offer the shortest route from Asia through the Suez Canal towards the countries of central and eastern Europe. The route is 2,000 Nm shorter compared to the northern European ports (NAPA, 2017). In addition, they are located on European TEN-T Adriatic Baltic and Mediterranean Corridor (Figure 1), and the land transport from this part of Europe to the countries of Central and Eastern Europe is shorter, as well.

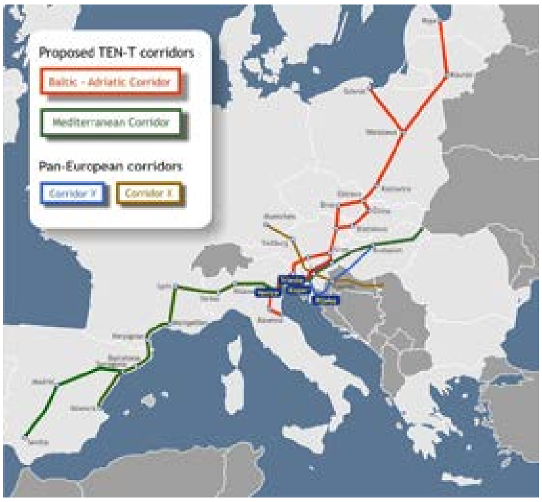

Fig. 1.
Location of NA ports
Source: http://www.portsofnapa.com

Northern Adriatic ports of Koper, Rijeka, Trieste, Venice and Ravenna are part of the European port system and they present a North Adriatic Port (NAP) system. These ports have the similar geographic characteristics and they work in a relatively closed system in which the market and customers are limited. For this reason the ports are forced to co-operate while at the same time compete with each other as they share a very similar gravitational area. Markets of NA ports includes northern Italy, the western Balkans, as well as countries of central and Eastern Europe. This is an area of great economic potential and the northern Adriatic ports control a moderate share of total overseas services for these countries presently.
The insensitivity of maritime traffic in NA ports is presented in Figure 2. The main transport corridor is to and from ports of Trieste, Koper, Venice, Ravenna and Rijeka that are at the same time the main ports in NA. In the figure are included also a touristic terminals, where the traffic in summer time is very intensive.

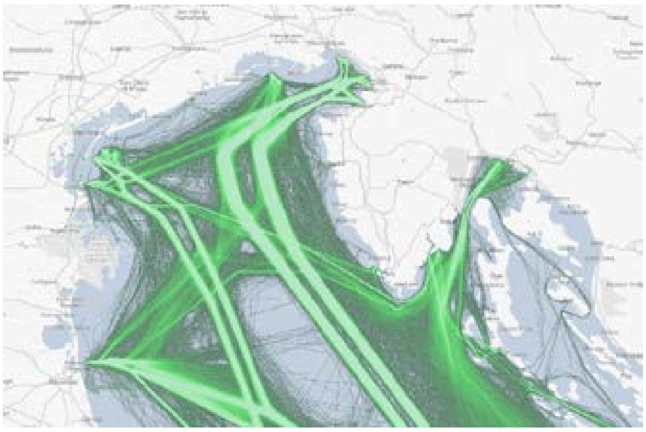

Fig. 2.
Maritime flows in North Adriatic
Source: https://www.marinetraffic.com/en/

The five NA ports are located in three different countries, with different transport policies and development plans. All the NA ports are international multipurpose ports and have their certain specializations, a factor that does not affect each other's business to a considerable extent.

Table 1
Characteristics of NA ports in 2017

	Koper	Rijeka	Venice	Trieste	Ravenna
Total throughput (mio t)	23,367	12,615	25,135	61,955	26,508
Total area [ha]	2.800	1.500	2.200	2.300	1.203
Length of quay [km]	3,3	8,65	30,0	12,0	5,9
No. of calls	1.995	na	3.459	2.339	2.939
Max sea depth [m]	13.5	14	11.4	18	10.5

Source: The data from the port authorities

The main cargo in the port of Koper are containers and cars, meanwhile dry bulk represent 33,9 % of all throughput. Liquid bulk is the main cargo in the port of Rijeka (63,4 %) and in the port of Venice (35 %). The biggest throughput is in the port of Trieste, where crude oil present 70,6 % of total throughput. In the port of Ravenna dry bulk presents 43 % and general cargo 39,8 % of total throughput.
Ports as a "nerve centre" are under the pressure of port performance, where very often economy issues are contradictory to the "green decisions". Consequently, ports must find a balance to follow both goals simultaneously.

3. Port of Koper as a Green Port

"Green Port" concept is a new concept of port development that is focused on the reduction of the emissions and on the implementation of greening approach in the further development. Therefore, there is a need of the implementation of policies relevant for reduction of the emissions of harmful substances in the atmosphere and in the sea, the appropriate landscape design with trees that absorb the noise and pollution, use of renewable energy for port operations and activities (solar, wind, energy from the sea), recycling… Port of Koper is located near to the old city centre of Koper and is part of the urban centre, therefore the port pays attention for the wellbeing of the people that live and work in this populated area. They aim is to ensure the preservation of the environment and to operate in symbiosis with the community. Slovenia's National Spatial Plan includes the plan for the expansion and spatial organization of the Port of Koper in accordance with legislative provision and strict environmental standards. Consequently, the port's development and future operational plans already include environmental guidelines.
The "green development" of the Port of Koper must take into consideration that the port is the most important generator of the development of transport and logistics in Slovenia. The port operate as a multifunctional port and is designed for the handling various types of goods. Activities are performed by twelve specialised terminals, i.e.: container and ro-ro terminal, car terminal, general cargo terminal, livestock terminal, fruit terminal, timber terminal, terminal for minerals, terminal for cereals and fodder, European energy terminal, alumina terminal, liquid cargoes terminal and passenger terminal (Port of Koper, 2018).
Port of Koper is connected to all major world ports by regular shipping lines and the number of ships' calls constantly increase. The distance from Koper to the main industrial centres in Central Europe is approximately 500 km shorter compared to the North European ports that represents good basis for further port's economical and infrastructural development. Road connections from port to the hinterland is excellent, but railway is the main type of transport for the transport of good to and from the port. Presently, over 650 wagons arrive to and leave the port on a daily basis and by

this 60 % of cargo is transported by rail. Consequently, the inland transport follows "green development" directions, with an aim to shift as much as possible cargo on trains.

3.1. Development of "Green port"

To become a "Green Port" is necessary to plan a growth of the port on proactive base. All the activities must be focused on greening approach - in the port and within supply chains. Port of Koper has accepted a detailed development strategy, where all activities of work and planning of the port include the field of environmental protection, energy conservation and environmental care. A detailed environmental policy is presented at their dedicated web site (http://www.zivetispristaniscem.si). Moreover, ESPO (The European Sea Ports Organization) awarded Port of Koper for creating a sustainable future for the port and its surroundings in 2014 (Port of Koper, 2018). Namely, ESPO performs regular surveys in all EU ports, to check if they obtain the environmental priorities. Their development strategy on environmental management is based on measures and solutions that should be introduced to meet legislative demands, with the use of best available technology, to insure as little as possible impacts on the environment.
To protect the environment and natural habitats, they follow some main guidelines that consist of the introduction of modern energy-efficient technology, monitoring and result reporting of emissions into the environment, prompt and efficient responses in emergency situations that can happen in the port, and with constant improvement of the environment management system. In this way, they ensure that the development of port operations is in balance with the environmental, social and economic demands.

3.2. "Green" Activities in Port of Koper

Port of Koper started with the green activities years ago. The port implemented international quality standards for the protection of the environment, health and safety and food safety management. Nowadays, they manage all operations in accordance with these standards. The constantly monitoring of the air, water and noise is necessary to improve the ecology of the port zone. By introduction of vegetation (more than 2,000 trees, including 200 olive trees, have been planted in the last ten years) and the creation of new habitats in port surroundings, the port of Koper is one of the cleanest and greener ports in EU.
Furthermore, the port started with the Waste Management Centre years ago, and they were the first port in the NA to include these green activities in the daily operations. In the Centre, by using appropriate recycling methods, they sort and collect majority of waste generated at the port for further processing. All biodegradable waste is managed in a way to be converted into compost. They provide these processing services also for other enterprises and concerns in the region.
One of the activity that can increase environmental problem in port is dredging. Today ships require a depth of at least 14 m and many ports must use dragging to accommodate such big vessels. This situation is also in the Port of Koper where natural depth on container terminal is 12m (Basin 1), meanwhile at the Basin 3 the depth is 17,2 m. In order to follow increasing carriers' of employing bigger and bigger vessels, they have to remove every year around 80.000 m3 of sediments in all. Part of this dredging material is used as row material for civil engineering application in the port area. With appropriate treatment this material can be used also as a building composite, but in this moment a production is still too expensive.
The biggest environmental problem presents a European Energy Terminal, where they handle coal and iron ore. The terminal area is exposed to a strong northern wind named bora that often blew over 100 km/h. In the beginning they used water spray system to prevent dusting in the wider area. In the last years they developed a paper mill sludge; the cellulose pellets that are a waste by-product of the pulp and paper industry. The dust-suppression system involves mixing the pelletized paper mill sludge with water and then spraying the resultant solution on the stockpiles of coal and ore. When the mixture dries, short cellulose fibres cover coal and ore with a crust that prevents dusting.
The green investments are done also on the Container terminal. Throughput of containers has grown very fast in the last years and the existing container terminal is at the limit of the capacity. With such an intense growth of TEUs transhipped in Koper, it is necessary to start with the construction on a new container terminal and reconstruction and extension of the current container terminal (Twrdy et al., 2013). The extension of Pier I for 100 metres and new warehousing surfaces for containers are in line with the estimated growth of traffic, as well as with the exploitation of present and future terminal capacities. New projects and potential investments at the container terminal are important steps for the development of the Port of Koper, enhancing its performance and increasing its market share. According to this Port of Koper purchased 2 Super Post Panamax cranes, 22 electrical RTG cranes and 2 RMG electrical cranes. All new investments in transport infrastructure equipment on container terminal are environmentally friendly and present a new step for the development of the port. Moreover, the new equipment, when moving, creates electricity and returns it back to the network. Newer devices thus return up to 15% of the electricity consumed for handling purposes.

3.3. New Activities for "Green port"

The biggest environmental problem in the port are ships. The CO_2 emissions that derived the ship on the berth present 74% of all emissions occurring during the sailing time of ship. The emissions from ships at the berth are 10 x greater than those from ports own operations (Gibbs, 2016). The solution is so called "cold ironing", that present on shore

connection between ship and terminal for providing electrical power to a ship while its main engines are turned off. In this way, ships have a power from the landside for refrigeration, cooling, heating, lightening and emergency equipment. For the ports, cold ironing requires significant modification of the existing electricity grid, which is a very expensive and relatively long lasting process.
In the case of Port of Koper, cold ironing system implementation were analysed during the Elemed project. According to the performed analysis, it was proposed construction in phases to enable better financial feasibility of the project and the gradual adaptation to the requirements. Proposed solution for the Port of Koper provides a flexible and open cold ironing concept, able to operate in a standalone mode or integrated in a future smart grid.
Other activities that are planned in Port of Koper are use of solar energy, where the roofs of warehouses shall be equipped with photovoltaic cells. The creation of biofuels from processing waste engendered by port operations is another action that is planned in the near future. With the use of 'grass-carpets' on the roofs of semi-open storage the port will look greener also from the top. These carpets have positive ecologic effects on the buildings themselves and on the wider environment. By reducing building overheating, they indirectly provide lower energy consumption for cooling processes during the summer period.
Establishment of Technology park with an exposition of typical machinery used in operations, will provide an overview, displaying the history of Koper, the development of the seaport and the new expansion projects, including the new sports and recreational facilities. A viewing platform will offer an impressive panorama of the port and its broader surroundings.
The long-term plans can be oriented towards smart port development, with the use of smart infrastructure and superstructure in every-day operations. By this, a smart lightening, smart waste collection and processing, smart water management and faster interventions in potential environmental disasters can be introduced. The interface port-city should benefit from such development. Namely, new foreseen smart technologies will speed-up ports' smart development, with special focus also on environmental issues and long-term sustainability.

4. Conclusion

Ports are complex environmental systems and all activities must be planed and monitored with the EU standards or recommendation. As example - there are presently no international requirements that would mandate or facilitate the use of cold ironing, but just international standards according to which cold ironing must be implemented in near future. For lowering air sulphur ports sector is acting as a driver on international political initiatives (recommendations) - for the ports and for the shipping companies. With these actions, they try to convince shipping companies to reduce carbon emissions.
Port of Koper intends to increase their cargo operations from the current 23,4 million tons to 30-40 million tons in five to ten years, almost doubling the cargo capacity, and potential number of vessels calling the port. Further development of Port of Koper will depend on the rate of investment in increasing capacity. Implementation of cold ironing enables the possibility of synergistic implementation of other necessary investments in Port of Koper. Proposed solution for the Port of Koper provides a flexible and open cold ironing concept, able to operate in a standalone mode or integrated in a future smart grid. Further investments in new machinery will decrease energy consumption and at the same time allow the return of a certain degree of electricity back to the electricity network. Furthermore, the upcoming smart technologies for the ports, and once introduced by the Port of Koper, will give a new basis for future port-city sustainable development.
To obtain sustainable development is necessary to obtain the balance between environmental issue and economic benefits. The enlargement of port area in Port of Koper is in accordance with Slovenia's National Spatial Plan, with legislative provision and environmental standards. The green port concept that anticipate less carbon emission, cold ironing and new equipment complies with these standards and present a positive effect on welfare and ecological protection of wider area.
In this context, cooperation with other North Adriatic ports and exchange of experiences is more than desirable and it has to be stimulated through future projects. Just with the common "green" strategy for port environment is expected to create a winning combination between economy and ecology.

MARKET CONCENTRATION OF STRATEGIC ALLIANCES MEMBERS IN THE MARITIME CONTAINER SHIPPING MARKET ON TRADE LANES PASSING ACROSS THE ATLANTIC AND THE PACIFIC – SELECTED ISSUES

Jędrzej Charłampowicz[1]
[1] *Department of Logistics and Transports Systems, Gdynia Maritime University, Poland*

Abstract: Strategic alliances have significant impact on Maritime Container Shipping Markets. The vertical and horizontal integration as well as mergers and acquisitions have changed the market dynamics. The MCSM is a strongly integrated market on the supply side. The aim of this paper is to determine, based on empirical data, whether this market is still competitive for its participants, whose are not party of main alliances, and operates services passing across Atlantic and Pacific. For this purpose the Herfindahl-Hirshman Index for members of alliances, namely 2M, THE Alliance and Ocean Alliance, was calculated. The results of computation indicate that the market is moderately concentrated for services passing through Atlantic and still competitive for services passing across Pacific.

Keywords: Herfindahl-Hirshman Index, maritime container shipping market, market concentration, strategic alliances.

1. Introduction

Maritime Container Shipping Markets (MCSM) are main part of the global supply chains, with respect to time and distance. Therefore maritime container shipping is one of the fastest developing transportation branch. The reasons of growing significance of container shipping are mainly possibility to transport almost every type of commodity and cost reduction due to simplify transshipment operations.
Introducing containers to the transportation process implied the need to change the existing transportation model in the way to enable integration of every branch (Notteboom, 2012; David et al., 2016; Charłampowicz, 2017). Every node of the transport process had to be modified to correctly operate containers. The maritime transport market had to adapt to the new conditions. It was made through readjustment of vessels for shipping containers and as a consequence also through readjustment of ports for their handling. This type of actions significantly reduces the transportation cost (Lee & Song, 2017). The reduction of transport costs catalyzed further actions of global trade liberalization. Containerization is considered to be one of the main factors for globalization in the 20th century (Bernhoffen et al., 2017). The dynamic growth of the new transportation branch strengthened the position of shipping companies. In 21th century enterprises, in order to further increase their market share, started to establish strategic alliances that led to reduced costs, risk sharing and increased efficiency of the service provided (Rau & Spinler, 2017; Charłampowicz, 2017).
The aim of this paper is to determine, based on empirical data, whether the market it still competitive for its participants on the supply side, whose are not members of main alliances, and operates services passing across the Atlantic and the Pacific. The paper is divided as follows:

- Section 2 provides brief characteristics of the MCSM;
- Section 3 describes the methodology and data;
- Section 4 presents results of calculations;
- Section 5 outlines research limitations;
- Section 6 discusses the results of calculations and presents final conclusions.

2. Maritime Container Shipping Market

2.1. Brief characteristics of the supply side of the MCSM

According to World Trade Statistical Review 2017, transport, as an exported commercial service, has 17,7 per cent of share in the commercial services (other services are: good-related services, travel and other commercial services). Transport as an imported commercial services has 21,8 per cent of share (WTO, 2017). In both categories there were around 5 per cent decline year-to-year. In the period of time 2006-2016, transport (calculated as an average of exports and imports), as a category in the commercial services of the world trade has noted growth of around 37 per cent, which is the slowest dynamics of increment among other categories (WTO, 2017). International seaborne trade has noted growth of around 2,6 per cent year-to-year (Review of Maritime Transport, 2017). In the period of time 2006-2016 the international seaborne trade has noted growth of approximately 33,6 per cent, with an average increase of 2,9 per cent yearly. Within maritime transportation, container shipping has around 16,7 per cent of share (Review of Maritime Transport, 2017). In 2016 global containerized trade expanded 3,2 per cent year-to-year, with volumes attaining an estimated 140 million TEU's (Review of Maritime Transport, 2017). In the period of time 2006-2016 the global containerized trade has noted growth of approximately 55,5 per cent, with an average pace of growth of about 4,8 per cent yearly.

[1] Corresponding author: j.charlampowicz@wpit.am.gdynia.pl

Table 1 presents the change of quantity and capacity of container vessels in last decade comparing last quarter of 2007 and 2017. Despite of decrease in the number of deployed vessels by around 4,3 per cent, there was significant increase in overall deployed capacity from 123,2 mTEU to 183,8 mTEU, which is almost 50 per cent growth. MDS projects (MDS Transmodal Container Shipping Bulletin November 2017, 2017), based on the ships on order and not taking into account those that will be scrapped, that by 2020 global fleet capacity could grow by 13 per cent with capacity, in ships of 15000 TEU or more expected to increase by about 64 per cent.

Table 1
Change in the total deployed capacity and total number of vessels

	2007 Q4	2017 Q4	Dynamics of growth
Total deployed capacity (mTEU)	123,2	183,8	49,2%
Total no of vessels	5097	4879	-4,3%

Source: own calculation based on MDS Transmodal Container Shipping Bulletin November 2017

Placing higher orders for container ships in recent years has caused an oversupply. Although, in 2016, TEU capacity per delivered ship was 12 per cent lower than in 2015, the new vessels are larger than existing fleet (Review of Maritime Transport, 2017). This situation continues to exert pressure on ports to accommodate to larger vessels. Due to cascading effect this trend also applies on smaller ports, forcing the authorities to constantly adaptation of infrastructure and suprastructure of container terminals. The main reason of introducing mega container ships was the need of achieving the economies of scale.

2.2. Strategic Alliances on the MCSM

The MCSM has to face very volatile and rapidly changing market realities (Notteboom, 2002). The way to prevent these unpredictable situations for the supply side of the market was market concentration. This concentration of the market on the supply side is expressed in twofold: subjective capital integration, and organizational and functional form expressed through alliances established on the main routes of container transportation (Grzelakowski, 2013). The reasons for these strategic agreements are: risk sharing, economies of scale, knowledge and technology exchange, vertical integration and strengthening of market position (Rau & Spinler, 2017). Referring to the service characteristics, where the main factors are port calls, average number of deployed vessels and average duration, there are minor differences among alliances (Panayides & Wiedmer, 2011). Research conducted by (Rau & Spinler, 2017) confirms that the main drivers of change in the alliances are: competitive intensity, alliance complexity cost and freight rate volatility, while shorter lead times increase market concentration. Participation in the alliance has no influence on management, including sales and marketing, pricing or maintenance of vessel (Stopford, 2009, p. 534), and besides alliances compete with each other (Lee & Song, 2017). (Hirata, 2017) found out that due to strategic alliances static equilibrium does not exist. Empirical study of (Hirata, 2017) revealed that liner companies makes only normal profit regardless of increasing concentration level.

The immanent feature of the transportation industry is its vulnerability to integration (Matczak, 2015). The MCSMs have witnessed unique transformations unheard of in other transportation sectors. Through mergers & acquisitions (M&A), as well as formation of alliances, the three major alliances controlled 80% of the market. Some M&As require the alliance to be reorganized (Lee & Song, 2017).

Participation in strategic alliances has numerous advantages, which affects the MCSM. First of all, presence in the alliance reduces costs and risks for alliance members, that are generally top operators. Strategic alliances affects on smaller enterprises, which cannot draw benefits from economies of scale or risk-sharing. The market power of the strategic alliances members rises battening on the smaller operators. Table 2 presents the members of the 3 main strategic alliances with their market share written in brackets.

Table 2
Members of the current main operating strategic alliances with their global market share (in brackets).

Name of alliance	Ocean Alliance	THE Alliance	2M
Members of the alliance	CMA CGM (11,7%)	ONE (7,0%)	APM-Maersk (18,0%)
	COSCO (9,2%)	Hapag-Lloyd (7,2%)	MSC (14,7%)
	Evergreen Line (5,0%)	Yang-Ming (2,9%)	
	OOCL (3,1%)

3. Methodology and Data

3.1. Market Concentration

Market concentration refers to the extent of which a small number of enterprises accounts for a large proportion of provision of goods or/and services on the researched market (OECD). According to the theory of industrial organization economics the higher market concentration, the higher possibility for entities engaging in monopolistic practices, which results with poor economic performance and misallocation of the resources. The ownership concentration, which is related to the supply side of the market, measures the extent to which shares of corporate assets (or market) are widely or narrowly held by business entities (OECD).

3.2. Herfindahl-Hirshman Index

Herfindahl-Hirshman Index (HHI) is based on the total number and market share of enterprises in the industry. This indicator is typically used by the regulators to provide an assessment of market concentration (OECD; Qazi et al., 2017). It is computed as a sum of the squares of percentage market shares of entities in the studied business. Mathematical formula for HHI is as follows:

$$HHI = \sum_{i=1}^{n} s_i^2 \tag{1}$$

where n stands for total number of examined carriers and s_i represents the percentage market share of the i^{th} carrier. The maximum value of HHI, according to equation 1, is 10000, which stands for pure monopoly (OECD). HHI below 1000 represents unconcentrated competitive market, value between 1000 and 1800 indicates moderately concentrated market and value above 1800 shows highly concentrated market (Qazi et al., 2017).

4. Results

Table 3 presents results of calculation of HHI for alliance members on services passing across the Atlantic. Table 4 shows results of computation of HHI for alliance members on services passing across the Pacific. Calculation has been made on data collected from MDS Transmodal Container Shipping Bulletin (MDS, 2016; MDS 2017).

Table 3
Results of calculation of HHI for members of strategic alliances – services passing across the Atlantic.

Name of alliance	Operator	Q4 2016 Operators' HHI	Q3 2017 Operators' HHI
2M	APM-Maersk	441	400
2M	Mediterranean Shg Co	676	676
THE Alliance	Ocean Network Express	4	49
THE Alliance	Yang Ming Marine Transport Corp.	1	4
THE Alliance	Hapag-Lloyd	196	100
Ocean Alliance	CMA CGM	144	144
Ocean Alliance	OOCL	1	4

Source: *own calculations based on MDS Transmodal 2017, AXS Alphaliner.*

On the services passing across the Atlantic HHI for 2M alliance members dropped for about 3,7 per cent. THE Alliance noted decrease of HHI in 23,9 per cent. HHI for Ocean Alliance, on the other hand, increased by 2,1 per cent. Overall HHI for the members of the three main strategic alliances, on the services passing across the Atlantic, dropped for almost 5,9 per cent from 1463 in Q4 2016 to 1377 in Q3 2017.

Table 4
Results of calculation of HHI for members of strategic alliances – services passing across the Pacific.

Name of alliance	Operator	Q4 2016 Operators' HHI	Q3 2017 Operators' HHI
2M	APM-Maersk	225	289
2M	Mediterranean Shg Co	49	25
THE Alliance	Ocean Network Express	225	225
THE Alliance	Hapag-Lloyd	25	25
Ocean Alliance	Evergreen	100	81
Ocean Alliance	CMA CGM	169	169
Ocean Alliance	OOCL	16	25
Ocean Alliance	COSCO Shipping Co Ltd	144	121

Source: *own calculations based on MDS Transmodal 2017, AXS Alphaliner.*

Regarding to services passing across the Pacific, the HHI for 2M alliance increased by around 14,6 per cent. The HHI for THE Alliance remained the same. The Ocean Alliance HHI dropped by around 7,7 per cent. Overall HHI for members of the three main strategic alliances, on the services passing across the Pacific, increased by 0,7 per cent from 953 in Q4 2016 to 960 in Q3 2017.

5. Research Limitations

The ability to utilize and have a full access to *Science Direct* journals made it possible to review the subject in interesting areas. None the less, the fact of relying on only one database greatly limited the possibility of conducting a more extensive literature research.
Another significant research limitation was connected with the lack of possibility of possession more empirical data from the market. The possibility to conduct research based on publicly available reports like UNCTAD Review of Maritime Transport and briefs reports such as MDS Transmodal Container Shipping Bulletin greatly limited the possibility of conductive more extensive research.

6. Conclusions and Discussions

MCSM has to face volatile and rapidly changing market conditions propelled by the increasing customer requirements, technology advances, political disruptions and intensifying competition. The most important factor, for market participants on the supply side, has become cost reduction. The way to achieve marginal cost reduction was deploying ever-larger vessels and consolidation. Through M&A and establishing strategic alliances the market position of alliance members has been strengthened.
The aim of this paper was to determine the market concentration of the MCSM on the services passing across the Atlantic and the Pacific using Herfindahl-Hirshman Index. The results of the calculations indicate that market is moderately competitive for its participants on the supply side. Calculated level of HHI for members of three main strategic alliances, on services passing across the Atlantic, indicated that this market is moderately concentrated (HHI=1377). However concentration level dropped for 5,8 per cent year-to-year, the 2M alliance captures dominant market share of this trade lane (46 per cent of market share). Members of main alliances (2M, THE Alliance, Ocean Alliance) captures 84 per cent of the market share, which leaves small business opportunities for competition for operators, whose are not members of the strategic alliances. Despite the dropping concentration level for operators from main alliances, the market share of all others operators has also dropped from 18 per cent in Q4 2016 to 16 % in Q3 2017.
Calculation of HHI level on services passing across the Pacific indicates that market is still competitive for its participants. Current level of HHI for all alliance members is 835, although this index has risen by 3,2 per cent year-to-year, which represents fragmentized, unconcentrated, competitive market. Comparing to the services passing across the Atlantic, this market is more divided, dominant market share (>50% of market share) is divided by 4 top operators from 2M and THE Alliance (APM-Maersk, ONE, COSCO and CMA-CGM combined have 51 per cent of market share). Members of three main alliances captures 75 per cent of the market share, which also leaves small business opportunities for smaller entities, although the concentration level of the market indicates that the market on the services passing across the Pacific is still competitive for its participants on the supply side.
The main conclusions of this paper are:

- MCSM heading towards to more concentrated market, where few operators will dictate the conditions for other participants;
- Market is moderately concentrated for services passing through the Atlantic, which means it is more difficult for operators, whose are not members of the main strategic alliances, to compete with the top operators;
- Market is still competitive for its participants on the supply side on the services across the Pacific;

SHIP PROPULSIVE PERFORMANCE ASSESSMENT AND GHG EMISSIONS REQUIREMENTS

Amoraritei Mihaela[1], Domnisoru Leonard[2], Popescu Gabriel[3]
[1,2,3] *"Dunarea de Jos" University of Galati, Faculty of Naval Architecture, Romania*

Abstract: Maritime transport represents a considerable source of Greenhouse Gases (GHG) emissions, with negative impact on environment and climate change. As a technical measure to quantify and reduce CO_2 emissions from ships, the International Maritime Organisation (IMO) has introduced Energy Efficiency Design Index (EEDI). After a brief overview of the issues related to shipping GHG emissions, the paper presents an assessment of propulsion performances for different type of merchant ships, taking into considerations EEDI requirements. Alternative combinations between diesel engines and optimal efficiency propellers have been analysed. For every ship type, size and speed, different diesel engines have been selected and propellers have been redesigned to absorb delivered power and to give maximum efficiency at the required speed. For every study case, an attained EEDI has been computed and compared with required IMO EEDI. The impact of two parameters from EEDI formula: power and speed has been assessed to find solutions for EEDI reduction.

Keywords: shipping emissions, ship propulsion system, EEDI.

1. Introduction

Actual trends in shipbuilding and shipping market, fluctuations in fuel costs and environmental impact of Greenhouse Gas (GHG) emissions from ships, demand propulsion systems designed to deliver the maximum efficiency with minimum fuel consumption.

As a technical measure to quantify and to reduce CO_2 emissions from ships, the International Maritime Organisation (IMO) has introduced Energy Efficiency Design Index (EEDI) measured in mass of CO_2 emitted per unit of transport work. In the continuous efforts to improve ship propulsive performances, to reduce fuel consumption and associated CO_2 emissions with their negative environmental impact, the indirect relationship between ship propulsion system design and EEDI criteria represents a real challenge for a naval architect. EEDI becomes an important tool in the design stage by improving ship hull, engine and propeller design and promoting less pollutant equipments.

After a brief overview of the issues related to shipping GHG emissions, the study includes an assessment of propulsion performances for two types of merchant ships, bulk carriers and container ships, taking into considerations IMO EEDI requirements. These two ships classes account 42% of the total shipping CO_2 emissions (Olmer et al, 2017) and represent around 54% of the cargo carrying fleet (Carlton et al, 2013). Alternative combinations between diesel engines and optimal efficiency propellers have been analysed. For every ship type, size and speed, different diesel engines have been selected and propellers have been redesigned to absorb delivered power and to give maximum efficiency at the required speed. For every study case, an attained EEDI have been computed and compared with required IMO EEDI (value calculated as function of ship type). The impact of two parameters from EEDI formula: power and speed has been assessed to find solutions for EEDI reduction.

2. Greenhouse Gas Emissions From Ships

Greenhouse Gases (GHG) trap and hold heat in the atmosphere and contribute to climate change. The main greenhouse gases are: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O) and fluorinated gases. To compare their contribution to global warming, data are expressed in carbon dioxide (CO_2) equivalents. The negative environmental impact for each gas depends on its concentration, how long it remains in the atmosphere and how strongly it absorbs energy (Global Warming Potential - GWP).

An important source of GHG emissions from human activities is fossil fuel combustion for peoples and goods transportation. In 2015 the European Union (EU) transport sector has been responsible for around 25.8% of total EU 28's GHG (EEA), in 2016 the United States transportation sector contributed with 28,5% of 2016 USA's GHG (EPA). Shipping GHG emissions account around 3% of global emissions and it is expected to grow in the next years. In EU, maritime transport GHG emissions represent 12.8% from total EU's transport GHG emissions (Figure 1), but compared with other transport technologies, it is generally considered the most carbon efficient and environmental friendly.

CO_2 is an important greenhouse gas emitted by ships. As result of fuel combustion, CO_2 shipping emissions depend on the quality and quantity of the fuel burned. In 2007, shipping emitted approximately 1100 million tonnes of CO_2 and was responsible for 3.5% from global CO_2 emissions (IMO 2014). In 2015, total shipping CO_2 emissions accounted around 932 million tonnes of CO_2 what was around 2.6 % from global CO_2 emissions (Olmer et al, 2017) (Figure 2). Regarding the percent share of CO_2 emissions by ship class, three types of merchant ships: bulk carriers, container ships and oil tanker, account around 55% of the total shipping CO_2 emissions (Figure 3) and represent around 84% of the cargo carrying fleet (Olmer *et al.,* 2017).

Fig. 3.
Average percent share of CO_2 emissions by ship class
Source: Data source ICCT (Olmer et al, 2017)

In 2050 the maritime CO_2 emissions are expected to be higher than in 2012, without further action on efficiency and emissions, based on different scenarios, increases between 50% and 250% may occur (IMO, 2014).
To reduce CO_2 emissions from ships, the IMO International Maritime Organisation has adopted in 2011 technical and operational energy efficiency measures for ships. As a technical measure, IMO has introduced Energy Efficiency Design Index (EEDI), mandatory for new ships from 2013. The Ship Energy Efficiency Management Plan (SEEMP) with Energy Efficiency Operational Indicator (EEOI) has been implemented as operational measure, in order to assist shipping company in managing ship energy efficiency.

3. Energy Efficiency Design Index

Energy Efficiency Design Index (EEDI) is a mandatory technical measure to reduce emissions from new ships. EEDI becomes an important tool in the design stage by promoting less pollutant equipments and improving ship hull, engine and propeller design. Expressed as impact to environment from shipping versus benefit to society, EEDI formulation is based on the ratio between total CO_2 emissions and transport work.

$$EEDI = \frac{impact\ \ to\ environment}{benefit\ \ to\ society} = \frac{CO2\ emissions}{transport\ \ work} \tag{1}$$

The CO_2 emissions depend on the installed power, respectively quantity and quality of fuel combusted in propulsion and auxiliary engines. The transport work is expressed as the ship capacity multiplied by ship speed. An attained EEDI (measured in g CO_2/tone-mile) must to be computed based on IMO formulation and guidelines and the value has to be below the limit required IMO EEDI.

$$EEDI_{attained} = \frac{Power \cdot CO_2\ conversion\ factor \cdot Specific\ fuel\ consumption}{Capacity\ \cdot Speed} \leq EEDI_{required} \tag{2}$$

The above formula represents the simplified form of Energy Efficiency Design Index. The relationship is more complex, including different coefficients and corrections factors to adjust the EEDI value for particulars situations. The EEDI formula is not applicable to all ships types and all propulsion systems. EEDI requirements have been developed and extended for ships of 400 GT and above, vessels responsible for approximately 85% of CO_2 emissions from international shipping (e.g., bulk carriers, container ships, tankers, general cargo ships, refrigerated cargo carriers, RoRo cargo ships, LNG carriers). Formula may not be applicable for ships with diesel-electric propulsion, turbine propulsion, hybrid propulsion system (except LNG carriers and passenger ships).
The required EEDI is the maximum allowable value of the attained EEDI and it is defined by a Reference line value, function of ship type and capacity, using following formula:

$$EEDI_{required} = (1 - x/100) \cdot Reference\ line\ value = (1 - x/100) \cdot a \cdot b^{-c} \tag{3}$$

where b is ship capacity, a,c values depend on ship type and x is a reduction rate according to year of built for new ships.
A brief analysis of the main parameters from attained EEDI equation is necessary in order to compute the index and to search technical measures and solutions to reduce it:

- *Power* for EEDI calculation is taking into account the power required for propulsion and auxiliary machines (measured in kW). Installed power is estimated in ship design stage and several solutions may be found to reduce it.
- *CO_2 conversion factor* is a non-dimensional conversion factor between consumed fuel and CO_2 emissions and depends on type of fuel used.
- *Specific fuel consumption* (measured in g/kWh) defined as amount of fuel use per unit of engine power is a characteristic of the engine.
- *Capacity* is defined as follows: deadweight for conventional vessel types, 70% deadweight for containerships, and gross tonnage for passenger and RoRo ships.
- *Speed* is the ship speed measured in knots and represents an important parameter in ship design.

The indirect relationship between ship propulsion system design and EEDI criteria represents a real challenge for a naval architect. Before main propulsion system selection, required propulsive power must be estimated function of ship resistance. Ship resistance is particularly influenced by ship speed, dimensional and form characteristics of the hull and its displacement. Improvements in ship hull dimensions, forms and hydrodynamics may lead to minimize propulsive power and EEDI reduction. Taking into consideration the cubic law between ship speed and power for a conventional propeller, a solution to reduce fuel consumption and CO2 emissions is to adopt lower ship speed. Another solution is to increase speed without increasing the installed power by improving propeller design and propulsion efficiency.
Propeller is one of the main components of a conventional ship propulsion system, with an important role in the interaction between engine and ship hull. Propeller has to be designed to absorb minimum power and to give maximum efficiency at the required ship speed. An optimal combination between engine power/speed and propeller diameter, a good flow in propeller plane shall improve the energy efficiency. In the continuing efforts to increase ship propulsion performances and to reduce fuel consumption and GHG emissions, various energy saving devices have been used into practice on shipbuilding market. Some energy saving devices have been developed to improve the flow around the propulsion and propulsive efficiency (e.g. full or semi-ducts, fins). Some unconventional propulsion and energy saving devices attempt to improve propulsive efficiency by producing thrust and reducing the rotational energy losses (e.g. contra-rotating propellers, rudder bulbs, etc.).
Other technical methods to reduce EEDI are: increase of ship capacity (deadweight), use fuel/energy sources with lower carbon content, use of renewable energy (wind power, solar power). Related to ship capacity, it is know that by

increasing ship dimensions and deadweight, installed power increases proportional with dwt at the power two-third, and taking into account EEDI formula (2), the increase of denominator exceeds that of numerator.

4. Propulsive Performance Assessment and EEDI Calculation

For the present study related to ship propulsive performance assessment taking into considerations EEDI requirements, two types of merchant ships have been selected: bulk carriers and container ships, with significant CO_2 emissions (Olmer et al, 2017) and over 50% of shipping. Bulk carriers are generally single screw vessels with high block coefficient, operating for long time at low and moderate service speed (around 14.5 knots or lower for bulk carriers with capacity below 30000 tdw). Fixed screw propellers directly coupled with slow speed diesel engines are used for propulsion. Propellers open water efficiency for bulk carriers are relatively low. Container ships design speed is around 15-27 knots, propellers open water efficiency have higher values and slow speed or medium speed engines are suitable.
The study was carried out for two different size bulk carriers (75000 tdw, 27000 tdw) and two container ships (4000 TEU and 500 TEU). Alternative combinations between diesel engines and optimal efficiency propellers have been analysed. Different diesel engines have been selected and propellers have been redesigned to absorb delivered power and to give maximum efficiency. Taking into account that propeller performances are related to ship speed, the work has been focused on propeller design and the impact of power and speed on EEDI formula. The aim was to find the best solution to increase propulsive performances and to reduce Energy Efficiency Design Index. For every study case, an attained EEDI has been computed and compared with required IMO EEDI (values calculated as function of ship type using parameters from Tables 1, 2).
For power estimation and propeller design, ship's resistance is necessary as initial data and the results related to effective power, given as ship resistance multiplied with ship speed, are plotted in Figures 4 and 5. It should be noted that the impact of hull forms improvement and ship resistance reduction on EEDI are not the subject of the present work.
For every ship type and size, for different slow diesel engines, the propellers have been designed to absorb delivered power and to give maximum efficiency at the required combination power-speed. A sea margin (SM) of 15% and an engine margin (EM) between 0 - 10% have been assumed in the propeller design. The main characteristics of the designed propeller are presented in Tables 3, 4.
Generally, higher propeller efficiency is associated with a larger propeller diameter and lower rpm. It is recommended to install the largest propeller diameter that can be accommodated to hull lines. In Tables 3,4, the values of designed propeller diameter have been marked with different colours: yellow for the maximum propeller diameter, green for the diameter corresponding to the minimum value of the attained EEDI, red for the diameter corresponding to the maximum value of the attained EEDI. For every study case (ship type and size, power engine, propeller design conditions) the engine power versus EEDI and the speed of the ship (obtained with designed propeller) versus EEDI have been plotted in Figures 6, 9 and Figures 7, 10. In these diagrams the required EEDI correspond to Phase 1 (2015-2019).

Table 1
Coefficients for required EEDI calculation

Ship type	a	b	c

EEDI requirements for bulk carriers and container ships have been plotted in Figure 8 and Figure 11, together with maximum and minimum values of attained EEDI for every ship type and size. For studied cases, all variations have been achieved by changing the main engine characteristics (power/speed, specific fuel consumption) and ship speed (obtained with optimal propeller designed to consume delivered power with maximum efficiency). The attained EEDI was not below required EEDI in all situations.

Most favourable results have been obtained for 75000 tdw bulk carrier, due to ship capacity and relatively low speed. In 6 cases the attained EEDI was below required EEDI phase 1. With the most efficient propeller (Case 7) a speed above 14.5 knots has been obtained with an attained EEDI below EEDI base line value. Cases 7 and 8 indicate the solution to reduce EEDI by increasing speed without increasing the installed power by improving propeller efficiency.

Energy Efficiency Design Index for bulk carriers

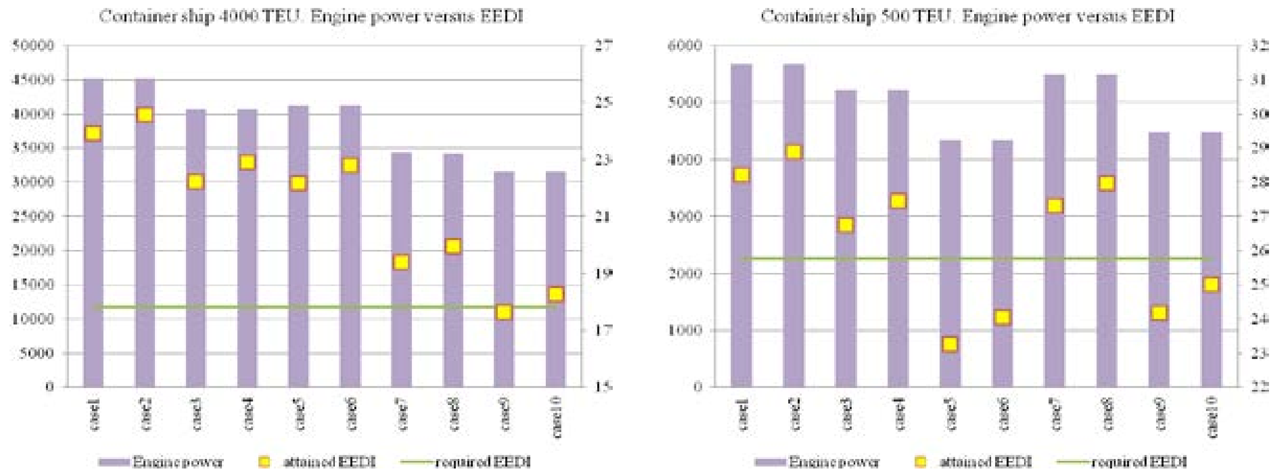

Fig. 9.
Engine power versus EEDI for container ships

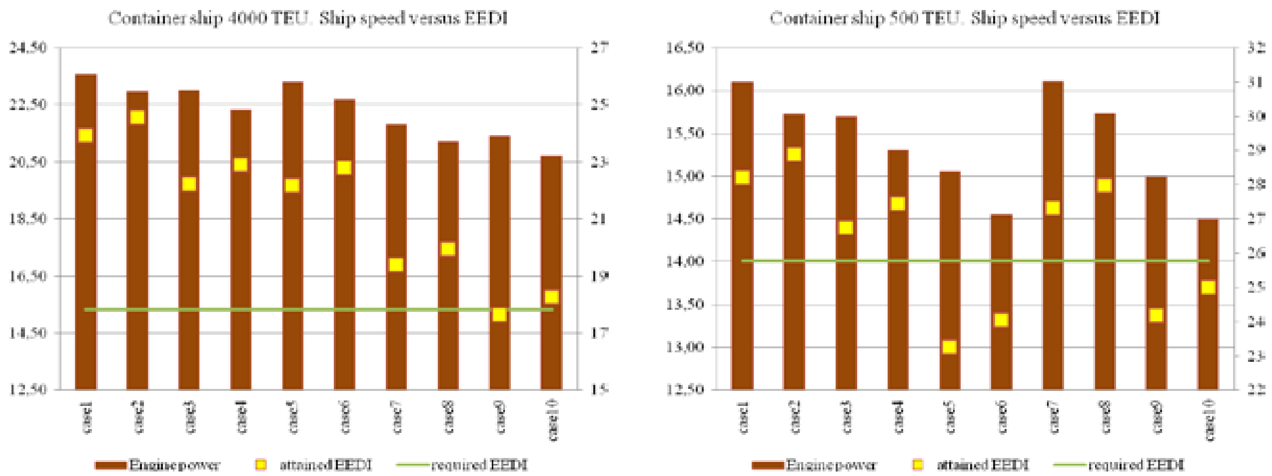

Fig. 10.
Ship speed versus EEDI for container ships

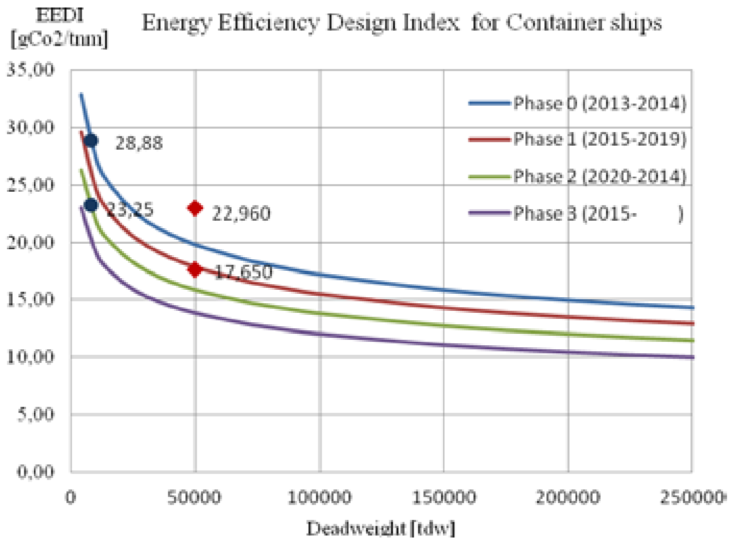

Fig. 11.
Energy Efficiency Design Index for containerships

Not the same things can be concluded about the 27000 tdw bulk carrier study. The only EEDI favourable case has been obtained by reducing engine power and ship speed (case 9). It should be noted that for this ship, the values of hull propeller interaction coefficients were higher. Hull forms improvements and most efficient combinations main engine/propeller may lead to EEDI reduction. The search for new two stroke engines with low revolution rate rpm and minimum fuel consumption may improve the results. For 4000 TEU container ship, only in case 9 the attained EEDI was below required EEDI phase 1, for the lower engine power and a relatively low speed. 4 favourable cases from EEDI requirements point of view have been found for 500TEU container ship, but for the ship's speed below 15 knots. For these 3 vessels, the choice of maximum diameter propeller did not lead to an attained EEDI below required EEDI phase 1. All the studied cases were presented, even if some results were unfavourable in terms of propulsion performance and/or EEDI requirements. Improvements in ship hull forms and hydrodynamics, search for other combination main engine/propeller may improve the results.

5. Conclusion

Actual trends in shipbuilding, fuel costs and environmental impact of Greenhouse Gas (GHG) emissions from ships, demand propulsion systems designed to deliver maximum efficiency with minimum fuel consumption. EEDI becomes an important tool in the design stage, being reduced by improving ship hull shape and less structural mass, engine and propeller design and promoting less pollutant equipments. In the continuous efforts to increase ship propulsive performances, to reduce fuel consumption and associated CO_2 emissions with their negative environmental impact, the indirect relationship between ship propulsion system design and EEDI criteria represents a real challenge for a naval architect. Fundamental to the ship propulsion system design is the selection of the main components (prime mover, transmission and propulsion) adjusting each to the constraints imposed by all other (Harrington, 1992) and integrating them into a functional system to achieve the required propulsive performances with low emissions and acceptable costs.

VEHICLE DYNAMICS ANALYSIS – WET ROAD SURFACE

Roman Mikulec[1], **Marek Semela**[2], **Michal Křižák**[3]
[1, 2, 3] *Brno University of Technology, Institute of Forensic Engineering, Czech Republic*

Abstract: This paper deals with vehicles' Škoda Superb III motion analysis during evasive manoeuvres and driving in the curve road tests with emphasis on usable coefficient of adhesion between tyre and road surface in lateral direction. All the individual road tests had been carried out both with and without using Škoda stability system ESC. Experimentally determined values of coefficient of adhesion and lateral acceleration have been utilized for the calculation of modern vehicle limit speed on wet surface in curve and for determination of the time of the lane change manoeuvres, which can be used for traffic accident forensic reconstruction. Many road tests have been carried out on dry road surfaces; this paper shows the difference of dry and wet road conditions as well. The tests show improved constant value which can be used for calculation of minimal time of lateral displacement in conventional formula.

Keywords: adhesion, lateral acceleration, driving, wet road surface, stability system, manoeuvre.

1. Introduction

At present, great emphasis is placed on vehicle safety. For this reason, modern vehicles are mandatory equipped with a range of assistance systems that help to maintain vehicle stability even under limited adhesion conditions. One of these systems is the electronic stability system (ESC), used in Škoda vehicles, which makes it possible to achieve higher lateral acceleration driving critical manoeuvres. This article deals with the experimental finding of the achievable lateral acceleration of the Škoda Superb III vehicles on wet surface and shows the differences between driving with the support of the assistance systems and without them as well.

There are many studies aimed at assessment of benefits of electronic stability systems in vehicles with respect to accident occurrence and their ability of accident avoidance. In traffic accident reconstruction in Canada (Chouinard, 2011) was found that presence of electronic stability systems has positive influence on accident occurrence. This was marked as the ESC efficiency and expressed as percentage decrease of accidents that could be influenced by presence of electronic stability system (loss of stability, avoidance manoeuvre etc.). Efficiency of ESC was determined to be higher during accidents with injury of the vehicle passengers. Other studies came to the similar conclusions as well (Page, 2006; Farmer, 2006; Lie, 2006; or Kreiss, 2005).

From the dynamic measurements of the vehicle's braking and braking performance in the curve (Panáček, 2016) it is clear that modern vehicles achieve similar acceleration (or deceleration) values both in the longitudinal and lateral directions regardless of driving speed and can use lateral adhesion even during intensive braking. At the same time, it has been shown that vehicles equipped with a stability system have the possibility to use higher adhesion coefficient than vehicles without these systems and achieve higher driving limits (Semela, 2015). For maximum efficiency, however, these systems require information about the actual value of the adhesion coefficient (Lee, 2004; Rajamani, 2010).

2. Experimental Section

As part of Škoda Auto company cooperation with Institute of Forensic Engineering, Brno University of Technology (IFE, BUT) several vehicles were provided for testing followed by crash tests. Two of those vehicles were used for dynamic tests as well. The main objective of these tests was to verify driving limits of modern vehicles on wet road surface and estimate the impact of assistance systems on achievable vehicle lateral acceleration.

2.1. Tested Vehicles

All the performed driving tests were carried out with modern vehicles Škoda Superb III 1.4 TSI with a manual transmission and Škoda Superb III Combi 1.4 TSI with an automatic transmission. Parameters of tyres (tread depth and tyre pressure) used on both vehicles are listed in tables below.

Table 1
Škoda Superb III tyres

2.2. Measuring equipment

For the purpose of determining the vehicle dynamic parameters a Racelogic VBOX Sport (GPS based measuring equipment) was used. During this testing a vehicle speed, acceleration and position were measured with the update frequency of this equipment of 20 Hz. Any driving input during the vehicle testing was observed using cameras VIRB Garmin Ultra 30 placed inside the vehicles. The position of steering wheel was also monitored by potentiometer.

Fig. 1.
Placement of measuring equipment
Source: IFE, BUT

2.3. Testing Course/Polygon

All the dynamic tests with Škoda vehicles were carried out on a special testing area used for truck testing – the Tatra Company in Kopřivnice (CZ). All the dynamic tests were carried out at the section of the testing area used for circular tests – the surface was made of asphalt, air temperature during the tests was between 7 and 15°C and there was permanent light rain during the testing.
Two series of testing were carried out with both vehicles. The first one was steady-state circular test – driver's aim during this test was to achieve limit speed of the vehicle while driving with and without the assistance systems, trying to maintain radius of the driving course 10 and then subsequently 20 m.
The second test was severe lane-change manoeuvre based on ISO 3888-2, where the driver's goal was to achieve maximum speed through the course while maintaining vehicle driving stability. All the tests have been for the reason of repeatability made by only one 30-years old experienced driver (this also allowed the driver to familiarize himself with both the driven vehicle and the test course thus allowing him to achieve limit speeds).

3. Results

During the dynamic tests carried out at the Tatra Company testing area in Kopřivnice 18 steady-state circular tests were performed by both Škoda Superb III and Škoda Superb III Combi vehicles. Each of the vehicles was tested on circular course with inner circle diameter of 10 and 20 m. All the tests were made with the ESC system enabled and disabled (this was achieved by pulling the control fuse of the assistance system out).
From the measured values of lateral acceleration were selected only those gained after reaching the limit speed of the drive. From these selected values a mean value of the lateral acceleration was calculated on 95% confidence interval (see figure below).

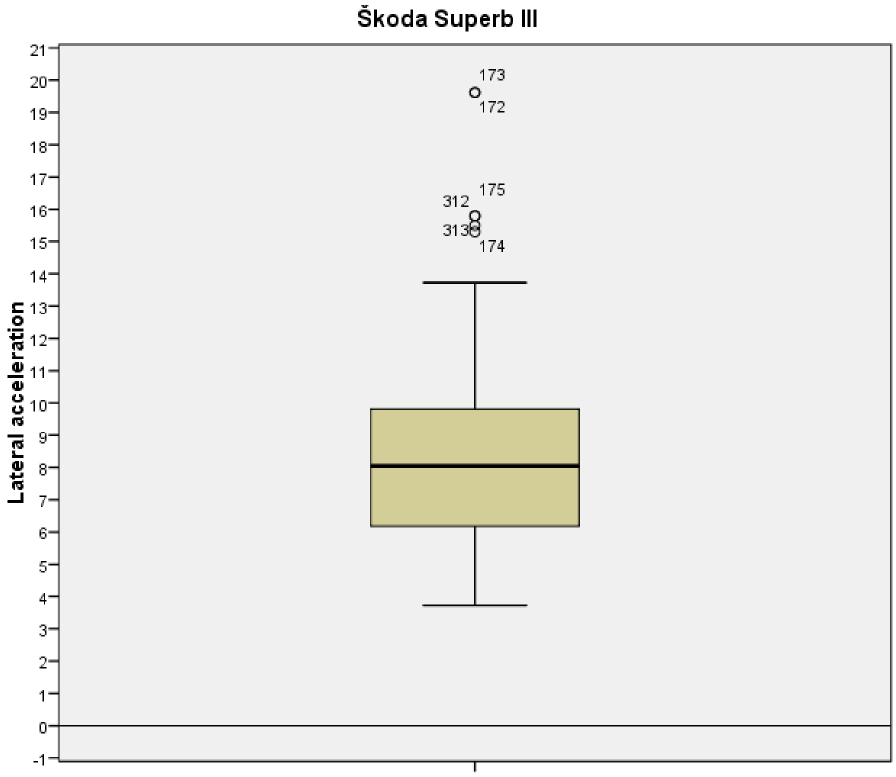

Fig. 2.
Mean lateral acceleration of Škoda Superb
Source: IFE, BUT

The results of both vehicles testing can be seen in the tables below. In the tables there can be seen whether the stability system (ESC) was activated or deactivated, inner radius of the driving course and average radius achieved by the driver during the test, average limit speed of the vehicle during the test and mean value of the lateral acceleration. There is also value of the coefficient of lateral adhesion calculated using following formula:

$$\mu_y = \frac{v^2}{g.r} \tag{1}$$

Where:

v – vehicle speed
g – gravitational acceleration
r – achieved radius of the test

Table 3

Škoda Superb III Combi was first of the tested vehicles. Unfortunately, precaution of the driver could be seen by prefatory tests, which is also visible from the lower values results of lateral acceleration. In the progress of time of tests on the same testing track, the experience and confidence of the driver increased and precaution decreased.

The second part of dynamic tests was severe lane-change manoeuvre. 12 tests with Škoda Superb III vehicle and 19 tests with Škoda Superb III Combi vehicle were carried out in total. From these tests 8 successful drives were picked for each of the vehicles as a representative sample showing limit values by normal vehicle. The goal of these tests was to determine the minimum time required to make the lane-change manoeuvre.

The length of the lane change manoeuvres has been estimated from the video records. The beginning of steering was set as the start time of the manoeuvre, as the end of the manoeuvre was considered by finalization of lane change manoeuvre on testing track (when the vehicle got completely to the same direction as before the manoeuvre). The results are introduced in tables below.

Table 5

Škoda Superb III lane-change manoeuvre length

It is possible to assume a sharp change of lateral acceleration with two maximums before vehicle stabilization (left and right) in case of lateral displacement with the help of two curves lane change manoeuvre. However, the course of the lateral acceleration of vehicle is comparable to sinusoid undulation. We could deduce theoretical formula for calculation of minimal necessary manoeuvre time, however we need to consider transitional curves as well in the beginning and end of the manoeuvre that prolong the minimal necessary manoeuvre time in sum.
For the purposes of traffic accident reconstruction in the Czech Republic are commonly used Weiss formula (Burg 2009) and so called Kovařík formula which only differs by using constant of 3.13 (opposed the Weiss formula that uses constant of 2.67).

$$t \geq 2{,}67.\sqrt{\frac{y}{a_y}} \tag{2}$$

Where:

t – minimal time of lane-change manoeuvre
y – lateral distance of the manoeuvre
a_y – maximal lateral acceleration.

With the later development of vehicles and based on carried out tests, the constant was changed to 2.6 (Bradáč 2005, Semela 2015).
As the alternative following formula can be used (Fundowicz, 2015) that calculates the distance travelled by vehicle in terms of lateral displacement manoeuvre. The formula reflects the gradual change (increase and decrease) of lateral displacement in terms of manoeuvre based on forces balance in lateral direction and it allows calculating the minimal distance travelled by vehicle during lane change manoeuvre.

$$S_{MIN} = v.\sqrt{\frac{Y}{1{,}56.\mu_y}} \tag{3}$$

Where:

v – vehicle speed
Y – lateral distance of the manoeuvre
μ_y – coefficient of adhesion in lateral direction.

Based on above mentioned, the durations of lateral displacement manoeuvres gained from video records and acceleration course were used for the calculation of empirical formula constant which is often used by calculation of minimal necessary time of lateral displacement. The average value of maximal lateral acceleration of vehicles on wet surface was about 8.5 m/s^2. The average lateral distance evaluated by GPS device was 2.8 meters.
The calculation of searched constant was made on basis of following formula:

$$k = t.\sqrt{\frac{a_y max}{y}} \tag{4}$$

Where:

t – minimal time of lane-change manoeuvre
y – lateral distance of the manoeuvre
$a_y$max – maximal lateral acceleration.

The constant was found to be 2.51, so we can assume that despite the wet surface, modern vehicle can achieve better values of lateral acceleration and that formula for calculation of minimal necessary time of lateral displacement can be always used, but with improved (lower) constants.

3. Discussion and Conclusion

By comparison of values of lateral acceleration reached during steady-state circular tests there could be observed differences between activated and deactivated assistance stability systems (ESC). Maximal values always depend on driver's experience and willingness to get vehicle to its limit while remaining in designated area of test track. The higher lateral acceleration values can be seen by vehicles with activated assistance systems (best seen at Škoda Superb III results).

During the steady-state circular tests it was possible to reach limit values necessary for the loss of the vehicle stability. This situation was evident for example during circular test at 10 m testing course radius with limit value of lateral acceleration reaching 10 m/s^2, vehicle was significantly tilted and the slip of left front impellent wheel could be seen.
The determination of minimal necessary time of lateral displacement by modern vehicles is depending on reachable value of lateral acceleration of the vehicle. The tests showed that in relating of tyre and assistance system development, the constant used for calculation needs to be corrected to lower values. For instance, the value of constant found by Panáček and Semela (Panáček 2016) was 2.6 by Volvo V40 AWD at dry surface and the last test shows the possibility to use the constant value of 2.5. Modern vehicles significantly move the limits of driving dynamics that can be best seen on achievable values of lateral acceleration during dynamic tests that reached 8.5 m/s^2 on average while driving on wet road surface, as this value is close to value of lateral acceleration measured during testing on dry road surface (Panáček, 2016), which was reaching 8.5 – 9.5 m/s^2.

MODERN TECHNOLOGIES IN RESCUING OCCUPANTS FROM SPECIAL VEHICLES USED IN THE LOGISTIC PROCESSES

Tomáš Binar[1], Jiří Švarc[2], Petr Dostál[3], Jakub Rozlivka[4]

[1,2] Department of Logistics, University of Defence, Brno, Kounicova 65, 662 10 Brno, Czech Republic

[3,4] Department of Technology and Automobile Transport, Faculty of Agronomy, Mendel University in Brno, Zemědělská 1, 613 00 Brno, Czech Republic

Abstract: The process of rescuing vehicle occupants through a blocked door is an integral part of logistic support in the field of all vehicles operation using in all the world. Rescuing human lives is a priority, and the logistic activities affecting the vehicle life cycle are dealt with afterwards. In this paper, a kit of special agents and technical means is designed for the purpose of penetrating into special vehicles used in the dangerous places and all the world in order to rescue their occupants through blocked doors or through armour protection (body). Practical verification tests of the new technology were devised and conducted. Based on these tests, the kit design was then finalised. For the penetration into a crashed or damaged special vehicle from outside, entrance openings were used. These were doors and lids. The technology was verified by six tests conducted on an armour door demonstrator. The first set of tests was based on a "cold process" technology, i.e. unbolting and the use of a combi tool. In the next set of tests, this technology included the use of a power cutter and a combi tool. In the last step was used the plasma for cutting the blocked door or through the armour. For this measurement was used the metalografical analysis of plasma cutters. The above-mentioned technical solutions have a positive impact on the management of state assets and form an inseparable part of the traffic's logistics.

Keywords: farmer, hinge, cordless cut off tool, combi tool, petrol power cutter.

1. Introduction

"Cold process" technology is based on unbolting and the use of a combi tool. The technology lies in unbolting door, or possibly lid hinges (where possible), and making an entrance opening between the door and the pillar on the hinged side, or between the lid and the roof, so that a combi tool could be inserted to prize the door or lid open. The combi tool also allows cutting a door restrictor. A similar problem was dealt with by the (Dostál et al., 2011; Dostál et al., 2014). The "cold process" technology comprising the use of a power cutter and a combi tool. This technology can be employed in cases when door or lid hinges cannot be unbolted and have to be cut with a power cutter. Using a claw bar, an entrance opening is made between the door and a pillar, or possibly between the lid and the roof, where a combi tool can be inserted to prize the door or lid open.

The world has material for special rescue operations at their disposal. This material is available at military rescue units – rescue companies of engineer battalions and military fire-fighting units. The material is similar to that commonly used by the units of Fire Rescue Service when rescuing occupants from crashed vehicles. Nevertheless, this material is insufficient for rescuing occupants from armoured vehicles, and its use is rather limited. A similar problem was dealt with by the (Binar et al., 2011, Sukáč et al., 2015).

Based on available information, it could not be proved the special vehicles on the world have portable rescue kits at their disposal that could be included into standard equipment of selected vehicles and used to open these vehicles.

Fire Rescue Squad, Rescue Platoon, Rescue Company are in possession of a HOLMATRO hydraulic rescue device, a power cutter, and lighting equipment, making the squad currently capable of efficiently operating and rescuing occupants from both crashed passenger cars and lorries by daylight and night. Nevertheless, this equipment is not sufficient for special vehicles. The similar advance did choose by the (Binar et al., 2015, Kazda et al.,2015).

Also, the Rescue Company makes use of salvage vehicles VT-72 (recovery tank) and AV-15 (recovery vehicle).The VT-72 tank may be used in an impassable terrain (shifting, tilting, overturning of crashed vehicles using a winch).

2. Materials and Methods

For the purpose of practical verification of the newly designed technology and the kit of special agents and technical means for the penetration into crashed or damaged armoured vehicles from outside, an armour door demonstrator was devised and manufactured. When devising the demonstrator, the team of researches took account of the requirement for the dimensions and materials to be the same as in the special vehicles (Binar et al., 2014; Joska et al., 2010).

The demonstrator consisted of a door frame and a door. The door, dimensioned 1,020 mm x 1,370 mm and 6.5 mm thick, was manufactured from armour plate of Secure 500 quality (refer to the annex for the attest).The door was fitted with hinges from 30 x 10 mm to 70 x 15 mm cross-section on the outside and with latches of 30 x 15 mm cross-section representing anti-burst latches (top and bottom) on the inner side and a door lock latch of 30 x 10 mm

[1] Corresponding author: tomas.binar@unob.cz

cross-section (in the middle). Also, on the inner side, the door was fitted with a restrictor made of a pole 20 mm in diameter. The hinges, the latches and the door restrictor were manufactured from materials of quality class 11 and 12 (refer to Fig. 1). The hinges were on the left side of the door and the anti-burst latches with the lock on the right side (ČSN 2004, ČSN 2005).

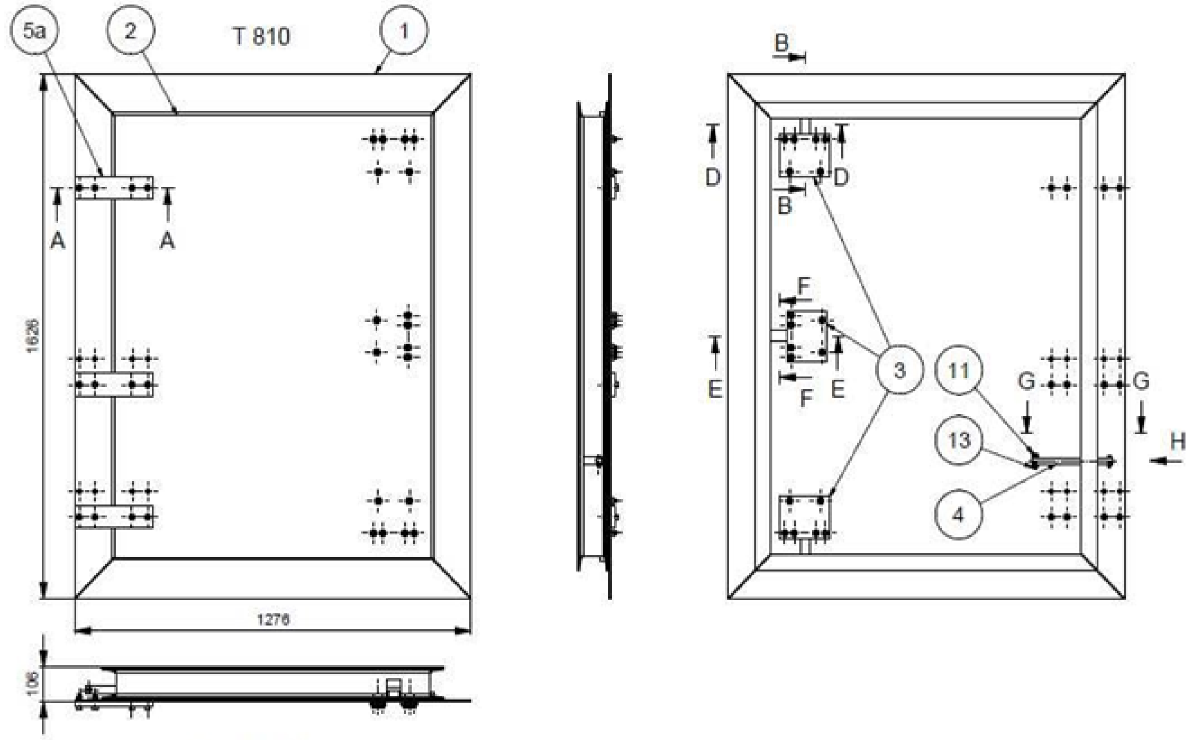

Fig. 1.
Scheme of a door frame and a door of an armour demonstrator

2.1. Tests of Penetrating Through an Armour Door Demonstrator

The following penetration tests were conducted on an armour door demonstrator using a "cold process" technology, comprising the use of a power cutter and a combi tool. For the testing, a newly designed kit of special agents and technical means was used.

2.2. Test no. 1 – Cutting Door Demonstrator Hinges Off Using a Cordless Cut Off Tool

During the test, 4 pcs of hinges of 30 x 10 mm cross-section were cut off. DEWALT DC415KL cordless cut-off tool with a NORTON Vulcan A cutting wheel 125x1, 6x22 A46S-BF41, Metal/Inox was employed.

2.3. Test no. 2 – Cutting Door Demonstrator Hinges Off Using a Petrol Power Cutter

During the test, 3 pcs of hinges of 70 x 15 mm cross-section were cut off.
A HUSQVARNA K960-K970/350 petrol power cutter with a diamond cut-off wheel 350 mm in diameter was employed.

2.4. Test no. 3- Cutting Door Demonstrator Hinges Off Using a Plasma Machine Cutter

For cutting during the test we used PLASMA 36 Invertor. During the test, 4 pcs of hinges of 30 x 10 mm cross-section were cut off.The Neophot 32 and the Olympus C-5050 digital camera were used for observation, photographic documentation and metalografical analysis.

2.5. Test no. 4 – Opening a Door Demonstrator By Prizing Off Anti-Burst Latches and the Lock

After door hinges were cut off, an attempt to open the door was made by prizing off anti-burst latches of 30 x 15 mm cross-section and a lock latch of 30 x 10 mm cross-section. A Holmatro CT 4150C combi tool with an SR 10 PC petrol pump was employed. On the hinged side, an opening between the door and the frame was prized open and wedged so that spreading points of the Holmatro combi tool could have been inserted. Then, the spreading points of the Holmatro combi tool were inserted between the door and the door frame on the hinged side, and an opening approx. 15 cm wide was made. The opening was then wedged, and the combi tool was moved to the opening as close to the anti-burst latches as possible. The door was opened by further spreading.

2.6. Test no. 5 – Opening a Door Demonstrator By Prizing Anti-Burst Latches and the Lock

Another test of the door demonstrator opening by prizing off two anti-burst latches of 30 x 15 mm cross-section and a lock latch of 30 x 10 mm cross-section was conducted by a hand-operated Holmatro combi tool.
A Holmatro HCT 5111 hand-operated rescue combi tool was used. On the hinged side, an opening between the door and the frame was prized open and wedged so that spreading points of the Holmatro combi tool could have been inserted. Then, the spreading points of the Holmatro combi tool were inserted between the door and the door frame on the hinged side, and an opening approx. 15 cm wide was made. The opening was then wedged and the combi tool was moved to the opening as close to the anti-burst latches as possible. The door was opened by further spreading.

2.7. Test no. 6 – Opening a Door Demonstrator By Prizing Off Anti-Burst Latches and the Lock

Another test of the door demonstrator opening by prizing off two anti-burst latches of 30 x 15 mm cross-section and a lock latch of 30 x 10 mm cross-section was conducted using Weber-Hydraulic equipment.
A Weber-Hydraulik door-opening kit was used. The kit contained a spreading device with a hand-operated pump. Hinges were first dismounted from the door demonstrator. On the hinged side, an opening was prized open between the door and the door frame and wedged so that a point of the spreading equipment could have been inserted. Then, the spreading points of the spreading equipment were inserted between the door and the door frame on the hinged side, and an opening approx. 10 cm wide was made. The opening was then wedged and the spreading equipment was moved to the opening as close to the anti-burst latches as possible. During spreading, the spreadi ng equipment was damaged by falling on the ground, and the process of opening by means of this equipment could not be finished.

3. Results and Discussion

For practical verification of the newly designed technology and thek it of special agents and technical means for the penetration into a crashed or damaged armoured vehicle from outside, 5 tests for the penetration through an armour door demonstrator were conducted. The door demonstrator copied the doors of key armoured vehicles used in the ACR (Pandur II CZ, Dingo, Iveco LMV and TATRA 810) in terms of its dimensions and materials used.
The “cold process” technology, comprising the use of a power cutter and a combi tool, was employed. When cutting hinges, a cordless cut off tool and a petrol power cutter were used. For the purpose of the door opening by prizing off anti-burst latches and a door lock, combi tool with a petrol unit, a cordless combi tool and a hand-operated combi tool were used. The times required for individual operations are stated in the table below:

Table 1
The results of armour door demonstrator penetration test

Test no.	Equipment	Source of energy	Operation	Time required [s]
1	DEWALT DC415KLcordless cut-off tool	battery	cutting hinges off	**180**
2	HUSQVARNA K960 K970/350 power cutter	petrol engine		**450** **145**
3	PLASMA 36 Invertor	petrol central		**180**
4	Holmatro CT 4150C combi tool	petrol pump SR 10 PC	door prizing	**140**
5	Holmatro CT 5111 combi tool	hand-operated		**240**
6	Weber-Hydraulik SPS 270 E Weber-Hydraulık door opening kit / hydraulic tool	hand-operated / battery		**300/30**

Note:1) 4 pcs of hinges of 30 x 10 mm cross-section were cut.
2) 3 pcs of hinges of 70 x 15 mm cross-section were cut.
3) The time of cutting using a HUSQVARNA RESCUE FR-3 wheel
4) A test of cutting the door restrictor was conducted in the length of 50 seconds

For a better image on the figure 2 you can see the metalografical analysis of plasma machine cutter. In the case of a flat plasma cut the armour on the upper surface is more affected. Here the heat-affected depth can be estimated at about 2,5 and 3,0 mm. The timeframe of them operation is the same as the time frame of the first measurement. This solution is most safer for breathing and comfortable for a crew in crashed vehicles compare when we used petrol power cutter.

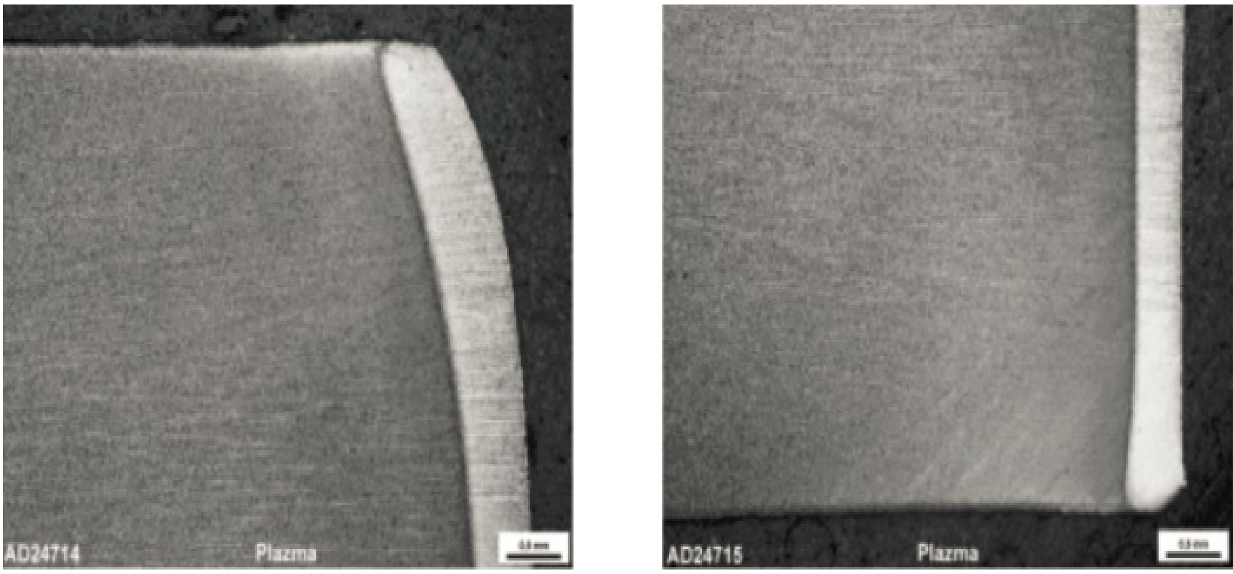

Fig.

Fig. 2.
Metalografical analysis of plasma cutters

The test results proved that the newly designed technology, tools and agents allow efficient penetration through an armour door demonstrator. The shortest time of penetration, i.e. below 5 minutes, is reached by the combination of HUSQVARNA K960-K970/350 petrol power cutter with a HUSQVARNA RESCUE FR-3 wheel and a Holmatro CT 4150C combi tool and an SR 10 PC petrol pump.

4. Conclusion

Six penetration tests were conducted on an armour door demonstrator using a “cold process” technology, comprising the use of cutters and a combi tools. In test no. 1, hinges on the door demonstrator were cut off using a cordless cut-off tool. In test no. 2, door hinges were cut off using a petrol power cutter. In test no. 3, cutting door demonstrator hinges off using a plasma machine cutter. In test no. 4, the door demonstrator was opened by prizing off anti-burst latches and a lock. In test no. 5, the door was opened by prizing off anti-burst latches and a lock. In test no. 6, the door demonstrator was opened by prizing off anti-burst latches and a lock.

The tests results proved that the newly designed technology, tools and agents allow efficient penetration through an armour door demonstrator. It follows from the results in Table 1 that the combination of HUSQVARNA K960-K970/350 petrol power cutter with a HUSQVARNA RESCUE FR-3 wheel and a Holmatro CT 4150C combi tool and an SR 10 PC petrol pump ensures the shortest time of penetration through the armour door demonstrator, i.e. below 5 minutes.

VEHICLE DAMAGE DURING PARKING MANOEUVRES

Stanislav Tokař[1], Anna Holyszewská[2]
[1,2] Institute of Forensic Engineering, Brno University of Technology, Brno, Czech Republic

Abstract: The article is focused on problems of damage vehicles during low speed turning manoeuvres of vehicles, so called parking manoeuvres. Based on the analysis of real typical events investigated by insurance company, five crash tests related to the most common courses originated while parking were performed. Performed tests only deal with parking into and out of the row of perpendicularly standing vehicles because this is the most widespread way of parking. Two new vehicles from Skoda manufacturer and three other older ones have been used for tests. The course of the crash test itself was documented and the attention was aimed at individual damages of vehicles during manoeuvres. Searching of interaction of individual elements on vehicles for possibility of regressive demonstration of mutual correspondence has been especially discussed. The attention was also paid to characteristic damages caused by vehicle impact configuration. Further on the examples of gained data at qualifying real insured events dealt with by insurance companies are stated. The purpose of the experiments was to qualify the technical acceptance of origin of the given vehicle damage depending on the description of the insured event. For the analysis itself the comparative method with performed car crash tests has been used.

Keywords: Vehicle damage, parking manoeuvre, insurance company, accident.

1. Introduction

Solving traffic accidents, when there are no injuries or deaths of people can seem to be insignificant. However, insurance company is the matter for which the insured events coming into being in collision at low speeds are more and more important. The reason are the increasing payments of insurance benefits. Proper solution of a damage event that came into being at a low speed is often difficult. Such damages are, from the point of view of financial means of insurance companies as demanding as much more serious traffic accidents. Crash tests, either carried out by the experts in the field of traffic accidents or by insurance companies´ employees are frequently the only possibility how to ascertain sufficient amount of quality documents and, subsequently, how to uncover a prospective intention to commit an insurance fraud. Committing insurance frauds in the field of insurance of motor vehicles is a serious problem in many European states. Solving insurance fraud became a major problem in the beginning of the 90s of the 20th century when it became impossible to overlook the ever-increasing number of the said cases. Uncovering such frauds became one of the main priorities of insurance companies that started developing algorithms for uncovering insurance frauds. Viaene (2002) dealt with the subject matter of insurance fraud on the general level. Viaene et al. (2004) dealt with the classification of the individual methods for uncovering frauds with vehicle insurance. Viaene (2009) dealt with the strategy for detecting fraudulent claims in vehicle insurance cases, where they focused on the procedure of general operational control of fraudulent claims in favour of those, which involve the phase of the preliminary inquiry, verification and the subsequent negotiation, which eventually lead to a court trial. If any discrepancy is found or absence of one or more key elements (the same statements of the participants, the corresponding damage of the vehicles, etc.). Then there is the suspicion, which can be classified as abusing the insurance benefits.
In the forensic practice, the above-mentioned topic was dealt with by experts like Burg (2009), Hugemann (2007) and Weber (1995). These sources show the general principles according to which we can manage insurance frauds: the least possible risk, realisation in the foreseeable time, reaching the maximum profit, minimal technical and organisational complications. Further, they describe the individual tools and methods, which are used for solving the cases suspicious of an insurance fraud, such as morphology (science of shapes), collision position, detailed assignment of characteristic traces and damage, and eventually the comparison of the intensity of damage. Moreover, the individual types of insurance frauds are being classified according to the type of their being carried out: intentionally, invoked, fictitious, provoked and used traffic accidents. Of course, if it is necessary to apply used methods when reconstructing traffic accidents such as described by e. g. Brach (2011), Rivers (2010), they can be used as well.
The matter of crashes of vehicles at low speeds is currently dealt with by the organisation RCAR (Research Council for Automobile Repairs), which works in the field of crash testing. The aim of these so called bumper tests is to use such systems in the automobiles that would decrease the costs of the repairs, if there was a front-end impact at speed of up to 15 km/h.
The motivation of carrying out the above stated tests was the absence of the known characteristics of damage in the improper manoeuvres within perpendicular parking. For the possibility of a more detailed assessment of the individual suspicious cases of damaged automobiles, the authors carried out their own series of crash tests at low speeds that are characteristic for the selected parking manoeuvres.

2. Performed Crash Tests

We used 2 modern and 3 older automobiles for the crash tests, which were already discarded. They were:
- Skoda Superb 2.0 TDI (2015) black color,
- Skoda Fabia 1.4 TDI (2015) black color,

[1] Corresponding author: stanislav.tokar@usi.vutbr.cz

- Opel Astra 1.4 16V (1998) silver color,
- Opel Vectra 1.8 16V (1996) red color,
- Daewoo Nexia 1.5 MPi (1996) green color.

The documentation was carried out by UAV (DJI Phanthom 3), a video camera (Panasonic HC-V720) and a camera (Nikon D7100).
The very interesting part for the experts can be the comparison of the damage, which comes into being in a crash at a low speed on a new and an older car. The culprit who commits an insurance fraud can use more cars of various age and value.

2.1. Damage of the Corner of a Parked Car and a Side of a Parking Car

The first crash test was carried out using a Skoda Suberb and an Opel Astra cars. The mutual crash of both the cars simulated the parking manoeuvre in which the driver of the Skoda car tried to park the car on the right of the Opel car. The speed of the parking car during the crash test equalled the above stated manoeuvre, i.e. approximately10 km/h. The Opel Astra car was parked at the right edge of its parking lot and none of its wheels was outside the designated lot. Such a parking space is typical especially for the car parks that are crammed, typically at shopping centres and in cities.
In the second test we used a Daewoo Nexia and an Opel Vectra cars. The parked Opel was damaged by the Daewoo, whose driver had not estimated properly the distance of the right side of his car from the parked car in the parking manouvre. The speed of the Daweoo car was also about 10 km/h, the Daewoo was at approximately the same angle of about 40 to 45°, when there was the contact of the cars, similarly to the first case, Fig. 1. The Daewoo car, partially went over the longitudinal border of the parking lot, which was the reason for the contact of rear bumpers of the cars.
The main difference between the two stated crashes was in the intensity of the crash and the damage of the cars, caused, especially, by the more significant depth of the deformation of the Skoda Superb car and Opel Astra. This higher crash intensity also caused a longitudinal shift of the parked Opel Astra car by 30 cm, the car had been secured by gearing the 1st gear. The Opel Vectra car clearly shifted its position in the second crash.

Fig. 1.
The course of the crash tests, left Skoda Superb x Opel Astra, right Daewoo Nexia x Opel Vectra

2.1.1. The Analysis of the Damage of the Cars Skoda Superb and Opel Astra

The parking manoeuvre, which was carried out by the driver of the Skoda Superb car at a small speed caused a damage on both the cars, however, a more significant damage was caused on the Skoda car, which caused the mutual collision. The first contact with the Opel car was visible on the left edge of the front door of the Skoda car, where the body of the car, namely the black varnish, was damaged. On the back door, there was, besides the abrasion, also a visible deflection of the car body, which came into being as a result of the contact of the door with the right part of the bumper of the Opel car. Furthermore, there was an abrasion of the varnish of the body of the car above the left rear wheel. The Opel car was damaged especially on the right edge of the rear bumper and the edge of the fender of the right rear wheel, Fig. 2.
Due to the damage of the body of both the cars and the height correspondence of the damage it was possible to prove the mutual crash. Even after the body of the car having been washed with warm water the door and the fender, it clearly

had visible grooves from the other car. In the combination with the caused deformation of the back door these are the marks that clearly prove the mutual collision of the cars.

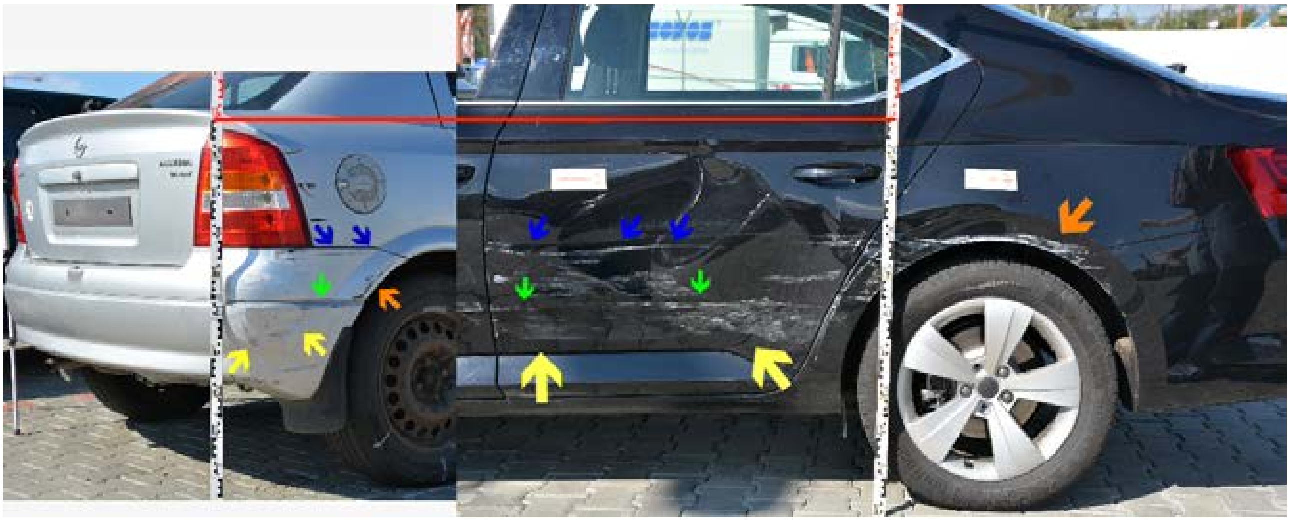

Fig. 2.
Correspondence of damage vehicles Opel Astra and Skoda Superb

2.1.2. The Analysis of the Damage of the Cars Daewoo Nexia and Opel Vectra

The Daewoo Nexia car, which caused the collision was damaged slightly more that the parked Opel Vectra car. The biggest damage of the Daewoo car was the semicircle abrasion of the varnish in the approximate height of 60 to 70 cm. This damage was probably caused by the cover of the rear light of the Opel car. On the green varnish of the Daewoo car we could also see the deflections and abrasions of its black varnish, which were, due to theis position, caused by the unvarnished part of the bumper of the Opel car. The varnished part of the bumper on the same level clearly showed green traces after the mutual contact.
Backward proving of the mutual collision is made more difficult by the fact that both the cars were older and they already had had some damage that was not linked with the test clash. The Daewoo was caused a dominant damage mainly in the area between the back edge of the door and the rear wheel of the car. This place corresponded with the varnish damage on the rear bumper of the Opel car. After washing the body of the red car with warm water most of the marks got completely lost, which can, in a real case, make the assessement more difficult.

Fig. 3.
Correspondence of damage vehicles Opel Vectra and Daewoo Nexia

2.2. Damage of the Side of the Parked Car and the Front Corner of the Parking Car

The third crash test was carried out by the Skoda Fabia and Opel Vectra cars, which had been parked in the other direction, i.e. the front part of the car was in the direction from the car park, and a slowly coming Skoda car was trying to park parallel with the mentioned car. As a result of a bad parking manoeuvre there was a slight contact of the car bodies in the angle of about 15º. The parked Opel Vectra had been secured by a handbrake. In the crash there was no shift in either transverse or longitudinal direction. However, the traces of the mutual contact of the cars were visible on

the front door of the Opel car and they followed to the handle of the back door. The varnish abrasion on the Opel car was whole without any more significant traces of interruption. The parking manoeuver was, therefore, done by the driver at a constant speed without stopping.
The crash test of the Skoda Fabia and Opel Astra cars simulated a parking manoeuvre when the Skoda driver was trying to park between two other parked cars, however, he crashed into one of them. The test showed a typical damage caused at a slow speed of a car bumping into a parked car under the angle of approximately 35°. The Skoda car first caused the damage on the right door of the Opel Astra car by its left front headlight and there was also the shift of the rear part of the parked car in the transverse direction. After that the Skoda Fabia driver started turning the steering wheel from the parallel position into the right position by which the car was supposed to be moved into the selected parking lot. Before finishing the whole parking manoeuvre the left front headlight of the Skoda car as well as the upper part of the bumper and the body of the car above the bumper damaged the Opel Astra car almost on the whole length of its body. In the final position both the cars were not parallel with the lines delimitating the parking lots for the cars. The Opel Astra car had been secured by handbrake for the whole time of the test.

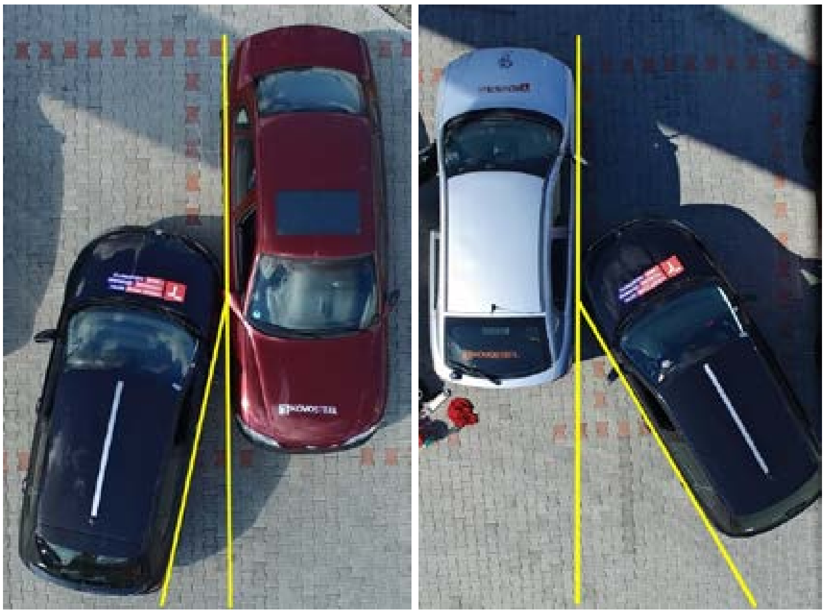

Fig. 4.
The course of the crash tests, left Skoda Fabia x Opel Vectra, right Skoda Fabia x Opel Astra

2.2.1. The Analysis of the Damage of the Cars Skoda Fabia and Opel Vectra

Mild abrasions of the varnish of the body of the Skody Fabia car caused by the crash test were only a surface damage. The first more significant groove was caused in the area of the edge of the bumper above the right fog headlight. Slight, consistent abrasion was also directly above the right part of the front bumper, approximately at the height of *55* to *60 cm*. While the Opel car showed noticeable abrasion on the upper part of the back door, the Skoda car did not show any damage at the same height. Due to the fact that in this case there was no colour coating, which would disappear after having been washed but a damage of the varnish as such, it could have been assumed that the abrasion on the Opel car had been caused by another part of the car that the varnished body of the Fabia car (possibly by the right front headlight of the Skoda Fabia car). The slight consistent abrasion on the Skoda car on the edge between the bumper and the right front fender corresponded with the protective bar on the door of the Opel car.
This crash test had the mutual contact of both the cars, however, it had not marked any of the automobiles with clearly visible marks, which would be the guide to proving the mutual collision. From this point of view, it had been almost impossible to prove backward the mutual collision of both the cars or determine the culprit of the crash. The traces upon the Škoda Fabia car had not disappeared after washing, however, they had not carried out any dentification signs.

Fig. 5.
Correspondence of damage vehicles Opel Vectra and Skoda Fabia

2.2.2. The Analysis of the Damage of the Cars Skoda Fabia and Opel Astra

Left front headlight of the Skoda Fabia car and the part of the body above the front bumper on the same side caused the damage of the body of the Opel car at the approximately same height of about 60 cm along the whole length of the silver car. As a result of a very low speed of the car that had done the braking manoeuvre in the wrong way the Opel car had been caused the typical wavy damage. The Skoda Fabia car was caused, as a result of the crash, depression on the left front headlight, depression, as abrasion on the left part of the bumper and the area right above it. The attachment of the headlight had not been damaged.
The bodies of both the cars showed damage that corresponded with each other regarding the height. Due to the range of the damage on the Skoda Fabia car, there was no doubt that the car had been a participant of a damage event. Backward proving of the mutual collision had again been very difficult. Significant deformation of the corner of the body of the Skoda car and a slight damage of the back door of the Opel car had not enabled the unequivocal primary crash configuration.

Fig. 6.
Correspondence of damage vehicles Opel Astra and Skoda Fabia

2.3. Damage of the Side of the Parked Car by the Corner of the Car going Backwards from a Parking Lot

The last test focused on going backwards from a parking lot when there were two cars parked on both sides. On the right from the Skoda Superb car going backwards from the lot there was an Opel Vectra car parked and it had been secured by a handbrake. The Skoda car driver first moved in the backward direction and then he started turning the wheels to the left. The bumper test simulated the parking manoeuvre when the drivers watch mainly the rear part of their car, however as a result of insufficient control of the front part there is a contact with the parallely parked car. In the second part of the parking manoeuvre the driver turned the steering wheel fully to the left and started going forwards to reach unblocking his car and to be able to go backwards again, Fig. 7. However, by this manoeuvre he damaged both the cars even more.

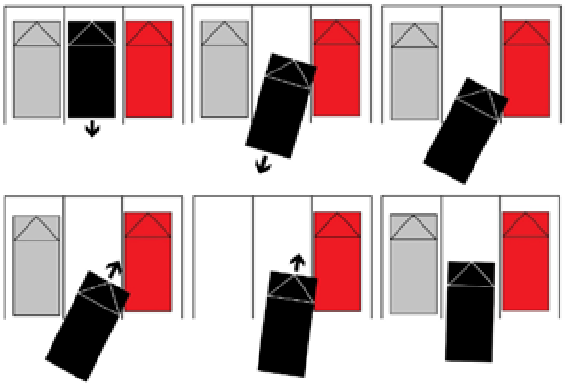

Fig. 7.
The course of the crash tests, up going backwards, down going forward

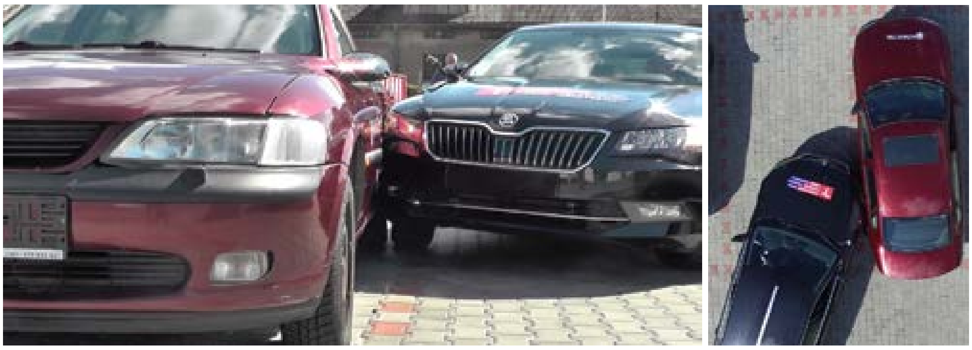

Fig. 8.
The moment of the stopping backwards going Skoda Superb

2.3.1. The Analysis of the Damage of the Cars Skoda Superb and Opel Vectra

The range of the damage on the Opel car was, after the first part of the parking manoeuvre (going backwards) larger than that on the Skoda car, also as a result of its being old and having visible corrosion on the body of the car. The corrosion was the reason for the full destruction of the edge of the rear fender. When going forward, the attachment of the headlight of the Skoda car was damaged. When exactly was the attachment torn away was clear only after finishing the whole bumper test and watching the video recordings.
Due to the fact that both the bodies of the cars were damaged, i.e Skoda Superb as well as Opel Vectra, it would be possible to prove the mutual collision even backwards. All the damage of the cars corresponded regarding the height.
Skoda Superb kept the groves even after having been washed, including those that still had the red varnish. To remove the marks on the black car of the culprit it would be needed to carry out an expert repair including cementing, edging, and overcoating of the damaged area.

Fig. 9.
Correspondence of damage vehicles Skoda Superb and Opel Vectra

3. Assessing the Crash Tests

3.1. Damage of the Corner of a Parked Car and a Side of a Parking Car

When comparing the crash tests of the cars Superb x Opel Astra with the test of Daewoo Nexia x Opel Vectra it was clear that the approach angle of the cars doing the parking manoeuvre was in both the cases almost the same. However, the analysis of the damage of the cars showed that while in the first bumper test there was a significant deflection of the body of the Skoda car in the area of the back door and a damage of the edge of the fender of the left rear wheel, the Daewoo car remained without a more significant damage. The range of the damage of the Skoda car can be attributed to the higher intensity of the crash and there was also a closer contact with the parked car and the shift . The Daewoo car touched the Opel Vectra car only slightly and the mutual abrasion of the car was only minimal.

3.2. Damage of the Side of the Parked Car and the Front Corner of the Parking Car

The angle of the approach of the cars within the above stated crash tests was different. While the Skoda Fabia car driver bumped the parked Opel Vectra car in the maximal angle of 15°, in the case of the crash of the Astra car the approach angle was more than double, i.e. approximately 35°. The analysis of the damage of the cars clearly showed that in the model crash of the Skoda Fabia car into the Opel Astra car there was a more significant range of damage on both the cars. If one car bumps into another one under the angle of about 35°, there is going to be a greater "penetration" into the corner of the body of the car than under the angle of 15°. The crash first slowed the Skoda car down significantly before finishing the manoeuvre and interrupting the contact between the car bodies. It can be assumed that in the case of the crash of the cars under a larger angle than 45° the parking manoeuver cannot be finished due to the mutual wedging of the cars.

3.3. Damage of the Side of the Parked Car by the Corner of the Car going Backwards from a Parking Lot

The test where the crash was done by a Skoda Superb car going backwards into the Opel Vectra car, brought an interesting finding useful for assessing real damage events. The first contact of both the cars was between the front corner of the Skoda car with the area of the front and the back left door of Opel car. The driver of the car kept on going backwards and only on the level of the rear fender of the parked Opel car he wedged the cars. At that moment the Skoda car driver had the possibility to align the steering wheel and try to continue going backwards or to try to free the mutually wedged cars by going forwards. If the driver decided to keep on going backwards, there would probably be even further damage of the bodies of the cars (varnish grooves, deflections) of the already damaged parts. The Skoda Superb car, however, went forwards by which it caused tearing off the right headlight from its attachment. In such cases the costs of the repair will be higher than if there was no tearing off of the attachment.

4. Solving Real Damage Events Using the Carried Out Crash Tests

Crash tests are often the only way to properly assess real damage events. The crash tests can provide an overview of the characteristic damage for the given manoeuvre. Subsequently, if the experts have a sufficiently wide database, they can use a simple comparison method to assess individual damage in case of real damage to vehicles. In particular, the fact whether the nature and location of the vehicle damage described corresponds to the course of its occurrence. In the following two examples, we will demonstrate the use of the information obtained from the crash tests described above.

4.1. Fiat Bravo x Audi A5

According to an announced damage a Fiat car allegedly damaged a parked Audi car when leaving a parking lot (going backwards). Subsequently, there was supposed to be another bump when the driver of the Fiat car finished going backwards and started going forwards. She stated the following information to the insurance company: *"When leaving the parking lot I damaged another parked car, I got into a skid"*. The owner of the damaged car stated*: "She was leaving the parking lot, she skidded on ice and bumped twice into my car – into the front part as well as the rear part."*
The bump into the front part of the parked car was assessed by the insurance company as real and the damaged party was paid a sum commensurate to the damage on his car. However, the second part of the parking manoeuvre was assessed as unreal. The damage of the back part of the Audi car had probably been caused by a different accident of an older date. This is so-called "used traffic accident".
For the described manoeuvre when a driver is going backwards from a parking space and simultaneously damages the front part of another parked car it is characteristic that the damage is in the area of the edge between the bumper and the fender. What is also typical is the damage of the front bumper.

Fig. 10.
Left: there is a drawing of the occurrence of damage, middle: there is the characteristic damage from the crash test, right: there is the real damage

The characteristic damage resulted from comparing picture material from the crash test of the Skoda Superb and Opel Vectra cars with the photographs of a real damage event. In the crash test there was a deeper damage of varied character as a result of the bad technical state of the other car. The areas of the edge between the front bumper and fender showed a similar character of damage, only of a smaller range, Fig. 10.

4.2. Skoda Roomster x Unknown Vehicle

The abrasion of the body of the Skoda Roomster car, and thus the occurrence of a damage event, was caused by an unknown culprit. It was an announcement of damage that the owner of the car should have covered from the accident insurance. The damaged party announced the following information to the insurance company: *"At the car park in front of the house an unknown car caused damage (deep abrasion) on the side of the co-driver."* The insurance company assessed the damage event as a real one, however, the culprit stayed unknown.
When two cars come into a slight contact on the sides, there is usually abrasion of the varnish on the body of the car on the edge of the front and the back door. The cause of this can be the fact that the sheet of metal is curved on the edge of the door. Making the sheet metal double improves the strength of the place and in the case of a contact with another car there is not such a springy reaction of the material. The result is a characteristic damage of the varnish of the body of the car on the edge of the front and the back door, Fig. 11.

Fig. 11.
Left: there is the characteristic damage from the crash test, right: there is the real damage

5. Conclusion

The damage of cars that came into being as a result of a crash at a low speed is, currently, paid more attention. These often come into being also because of manipulated damage events. Sometimes the border between a real accident and an insurance fraud is very difficult to recognize and the assessment of some cases is not easy.
Five crash tests that dealt with parking into and out of the row of perpendicularly standing vehicles s were carried out. The photographs of each test documented the damage, which was caused as a result of the crash. The assessment of the model cases of the carried our parking manoeuvre showed several facts. It is the speed and the angle of the crash that has the significant influence on the damage of both the cars. In the case that the angle is smaller than 15° there is only slight abrasion of the cars and the damage is not of a large scale. In the case of the approach angle being more than 15° there is deeper abrasion of the body of the cars as well as slight deformations along the whole length of the side of the parked car. If the cars crash under an angle that is bigger than 45°, there are significant deformations at a particular spot. The drivers, who crash into a parked car in an incorrectly carried out manoeuvre can, in their effort not to cause any more damage, make the situation even worse.

Acknowledgements

To conclude, authors of this article would like to express their thanks to all colleagues and collaborating experts, who helped with the arrangement of performed crash tests. They would also like to thank the Skoda Auto Corp., Kovosteel Recycling Ltd. for provision of vehicles and space and Czech Insurance Corp. for vehicles damages from real accident.

VEHICLE PROCUREMENT CRITERIA EVALUATION

Marko Stokić[1], Davor Vujanović[2]
[1,2] University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, 11000 Belgrade, Serbia

Abstract: The vehicle procurement is one of the several factors which influences the vehicle fleet energy efficiency. The appropriate choice of vehicle reduces transport and maintenance costs. During vehicle procurement process managers consider many different interdependent criteria that have a different impact on the vehicle fleet energy efficiency. In this sense, vehicle fleet managers are faced with a problem how to determine the relevance of criteria in order to increase fleet's energy efficiency and decrease the transport and maintenance costs. In this paper, the authors have conducted a survey among vehicle fleet managers in transport and logistics companies evaluate which criteria are more important to them and which are less important. Also, the survey was conducted among students of Faculty of Transport and Traffic Engineering in order to compare their results with the experts results. Authors gave 30 criteria that were evaluated. As result of conducted survey the most important 3 criteria from experts point of view are adaptability of the vehicle to the transport requirements, fuel / energy consumption and preventive maintenance costs.

Keywords: vehicle procurement, energy efficiency, criteria, vehicle fleet.

1. Introduction

Transport and logistics companies with their own vehicle fleet for freight transport are observed in this paper. The main goal of these companies is to maximize profit by providing transport and logistics services. This goal can be achived through reducing transport (TC) and maintenance costs (MC), on the one hand, and on the other, by increasing energy efficiency (EE) of vehicle fleet. Vehicle fleet management is important tool for reducing CO_2 emissions and fuel costs, i.e. transport costs, as well as to improve transport sustainabillity (Ansaripoor et al., 2014). Vujanović et al. (2010) in their paper emphasize that companies are trying to increase their own vehicle fleets energy efficiency. In this respect, one of the several ways to increase energy efficiency is the implementation of integrated fleet maintenance management (Vujanović et al., 2017). According to the Federal Railroad Administration (2009) increased energy efficiency can be achived through various improvement measures, such as engine improvements and emission regulations, non-engine technological improvements on vehicle and changes in fleet composition, operational measures. Regarding to this, by using the Exhaust gas recirculation system, in the first decade of 21st century, fuel consumption decreased by additional 6% (Federal Railroad Administration, 2009). Besides that, an increase in energy efficiency can be achived by using aerodynamic devices on the vehicle (Saricks et al., 2003), by reducing vehicle weight (Maintenance Council, 1998), by using wide-based tires instead of using double tires (Federal Railroad Administration, 2009), as well as with operational measures which involve the application of modern information technologies (McKinnon, 1999).

The vehicles during their operational lifetime cause increasing of transport, maintenance and spare parts costs (curve 1), from one hand and from the other the level of availability and technical reliability decreases (curve 2). At the moment when the cost curve exceeds the „acceptable costs“ line (line 3), or the curve of the required availability / technical reliability is below the required level (line 4), the vehicle fleet renewal is considered by vehicle fleet managers (Figure 1). P_k is quality indicator. (Bunčić & Momčilović, 2014)

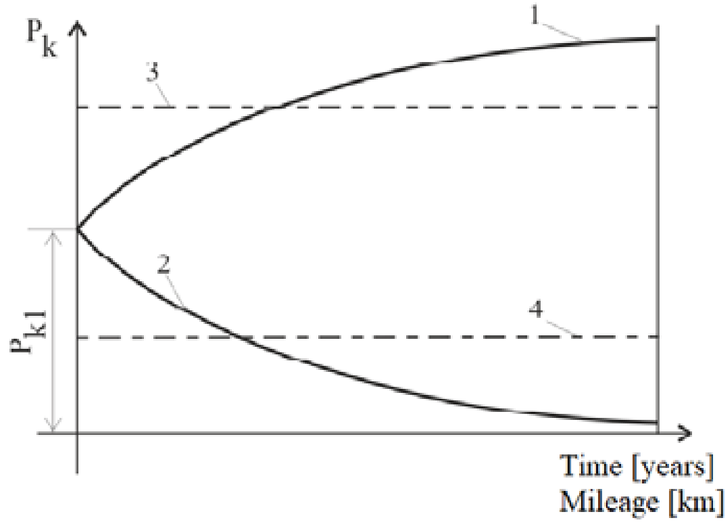

Fig. 1.
Curves of vehicle costs and technical reliability during vehicle operational lifetime

[1] Corresponding author: m.stokic@sf.bg.ac.rs

According to Stokić et al. (2018), the number of vehicles in EU is growing and there is a growing need for efficient vehicle procurement process management. The vehicle procurement represents one of the basic activities of vehicle fleet operation management and key precondition for efficient transport system operation, i.e. cost-effective usage, availability, maintenance, as well as vehicle environmental sustainability (Manojlović, 2012). Besides that, the insufficiently good choice of vehicles during the procurement process can also increase the transport and maintenance costs and to decrease vehicle fleet energy efficiency, which all together contribute to achiving less profit than it is possible (Stokić et al., 2018). In order to make the right decision during vehicle procurement process, the vehicle fleet managers need to consider several different criteria. Regarding to this, the criteria that should be considered during decision making process are defined in this paper. This contributes to the energy efficiency increasing, overall transport and maintenance costs reduction for a given volume of transport work, which enable observed companies to achive defined goal.

The paper is structured as follows. The chapter 2 shows literature review regarding the criteria that are considered during vehicle procurement process. The criteria classification is presented in chapter 3, while the chapter 4 is dedicated to the conducted research and analysis of the obtained results. The conclusion and future research are given in chapter 5.

2. Literature Review

In this chapter is given a literature review of the papers of the other authors who dealt with the vehicle procurement problem, as well as the criteria that need to be considered in order to successfully solve this problem.

In his work, Fourie (2010) considers the transformation of a vehicle fleet in the most cost-effective way. In that sense, Fourie (2010) states that it is necessary to consider a vehicle that meets the transport requirements in the best possible way, as well as is it better to buy a used vehicle (older or newer) or to purchase a brand new vehicle. Based on this, it is necessary to consider all costs, both variable (cost of driver labor, depreciation, vehicle operational costs, fuel economy, insurance, corrective maintenance cost, fuel consumption, oil, tires and preventive maintenance costs) and fixed, related to the vehicle operation. In addition, the brand and vehicle type have great importance regarding to transport and maintenance costs. Also, it is important if there is a certain discount that a sales agent can offer, as well as financial benefits from financial institutions (credit or leasing). Among the most important criteria is the useful load capacity of the vehicle. (Fourie, 2010). Ansaripoor et al. (2014) used stochastic programming and conditional value risk in their work to calculate the uncertainty in the vehicle procurement decision making process. The main goal of their paper was to reduce costs and risk simultaneously. They observed criteria such as average fuel prices (current and future projection), average electricity price needed for powering batteries for electric vehicles, operating costs for different fossil fuel technologies (diesel, gasoline and electric), fuel and electricity consumption per 100 kilometers, as well as pollution costs caused by CO_2 emission. Total fixed vehicle costs, monthly vehicle leasing costs and monthly leasing costs for batteries (for electric vehicles) were also observed. Lin et al. (2009) in their paper have tried to apply DEMATEL method in order to deal with the importance and causal relationships among the evaluation factors of alternative fuel vehicles (six different alternative fuels were observed). For the purpose of their research Lin et al. (2009) observed 21 different criteria that were divided into 5 groups, such as safety (leak safety, fuel ignition safety, refuel safety, in vehicle fuel storage safety and storage safety); pollution (air, noise, leak, discard); performance (cruising range, refuel rate, horse power, torque, fuel efficiency); accessibility (fuel accessibility, accessibility in usage, maintenance accessibility); costs (repair cost, maintenance cost, fuel cost and new car cost). As the first three criteria, the authors quote "new car cost", "cruising range" and "fuel efficiency". Also, "air pollution" is a criterion that has an impact on the all other criteria, while the criterion that is influenced by the all other criteria is "cruising range" Lin et al. (2009). Vujanović et al. (2010) state that the vehicle fleet energy efficiency can be increased by using more efficient engines with new technologies applied, as well as by proper selection of the vehicle type for a specific transport task (better utilization of the cargo space). Besides technologies applied to the engine, energy efficiency can be increased by implementation of new technologies that are applied specifically on the vehicle in order to improve vehicle aerodynamics, reduce rolling resistance, reduce vehicle mass, improve vehicle transmission. Also, new technologies that can be applied on the vehicle are electronic speed limiter and use of better motor oils. Although they do not specify specific criteria, Nicolas et al. (2014) in their paper state that during vehicle procurement process attention should be on sustainable mobility (social, ecological and economic). Regarding to this, the vehicle environmental aspect should be taken into account. The vehicle procurement process must be observed through the vehicle safety, vehicle age, emissions and cost efficiency criteria (OECD/ITF, 2011). Also the criteria such as vehicles compatibility, reliability, fuel efficiency, vehicle environmental level, warranty, procurement costs determined by state contracts, vehicle operation lifetime, relationship with vehicle manufacturer (does the manufacturer provide good customer support), development and availability of sales network and the value of the used vehicles should be considered as well (McDaniel et al., 2009). Degirmenci et al. (2017) in their paper were researching whether the ecology is ahead of electric vehicle price and vehicle range confidence, from the aspect of buyers. They observed the ecological performances of vehicle, vehicle price and range confidence, based on which they carried out research among users.

All mentioned criteria can be devided in several groups. Detailed division of criteria is expleined in next chapter.

3. Criteria Classification

Within this chapter a clasification of the criteria which are observed during vehicle procurement process was carried out. All criteria have impact on either transport costs or maintenance costs, while some of them are closely related to the vehicle energy efficiency. Also, the observed criteria can have multiple impacts, regarding to that, some of them can simultaneously affect transport costs and maintenance costs and energy efficiency. One example of criterion that has a threefold impact is the vehicle age. Older vehicle causes higher fuel consumption and therefore higher transport costs and greater impact on energy efficiency than newer one. In addition, older vehicle require more frequent interventions for both preventive and corrective maintenance.

All criteria can be classified into four basic groups. The first group includes constructional criteria that define the vehicle construction characteristics that must be met in order to successfully complete the transport tasks. This group includes vehicle dimensions, turning radius, vehicle power, capacity, adaptability to loading and unloading operations, type of drive, etc. The second group of criteria implies the initial costs of vehicle procurement (the price of a new / used vehicle). This group of criteria has great importance in order to carry out the vehicle classification (to separate vehicles which price is above and below planned budget for vehicle procurement). The third and perhaps the most important group of criteria for a good choice of vehicles is a group of vehicle operation criteria. This group includes the age of the vehicle, mileage, the warranty period, the vehicle maintenance cost (in the warranty period), coverage of service centers, vehicle repair costs (when the vehicle is not in the warranty period), fuel economy, fuel price, spare parts availability, the possession of modern on-board systems that increase the safety and energy efficiency (for example Forward Collision Warning System and eco-driving systems that provide active support to the driver while driving etc.). Last, but not the least significant group, there is a group of post-operation criteria that include the vehicle residual value when replacing (reselling), the recyclability of vehicle parts and the recyclability of whole vehicle.

Although the criteria are different and divided into different groups, they are mutually dependent, i.e. the criteria from one group can affect one or more criteria from another group. For example, the vehicle price is influenced by the equipment that vehicle consists in, engine power, useful vehicle load, etc.

As it is mentioned above, all criteria can be divided into four different groups and every criterion have a particular impact or on transport costs or maintenance costs or energy efficiency, but some of them may have multiple impacts. The authors selected 30 criteria on the basis of literature review, their own experience and through interview with experts. These criteria are given in Table 1., as well as their affiliation to these groups and their impact on transport costs / maintenance costs / energy efficiency.

Table 1

Observed criteria and their affiliation to groups and impact on transport costs / maintenance costs / energy efficiency

Criteria	Name	Group*	Impact**
C1	Vehicle price	II	TC
C2	Fuel / energy consumption	III	TC, EE
C3	Price of fuel used by the vehicle	III	TC
C4	Price of spare parts (for corrective maintenance)	III	MC
C5	Preventive maintenance costs (services)	III	MC
C6	Maintenance costs during the warranty period	III	MC
C7	Discounts that can be made when buying a vehicle	II	TC
C8	Financial benefits when buying a vehicle (credit / leasing)	II	TC
C9	Remaining value of the vehicle when replacing (reselling)	IV	TC
C10	Construction characteristics of the vehicle	I	TC, MC
C11	Compliance with transport requirements	I	TC, EE
C12	Compatibility with existing vehicle fleet	I	TC, MC
C13	Useful vehicle capacity	I	TC, EE
C14	Engine power / torque	I	TC, EE
C15	Tank / battery capacity	I	TC, EE
C16	Existence of on-board security systems	I	MC
C17	Possession of cruise control	I	TC, EE
C18	Vehicle condition – mileage, age	III	TC, MC, EE
C19	Type of drive (conventional, alternative, hybrid, electric)	I	TC, MC, EE
C20	Air pollution caused by vehicle	III	EE
C21	Noise caused by the vehicle during operation	III	EE
C22	Possibility to rebuild a vehicle to use an alternative drive	I	TC, MC, EE
C23	Possibility to recycle parts and the vehicle after use	IV	TC, EE
C24	Good previous experience with the vehicle manufacturer	II	TC, MC
C25	Duration of manufacturer's warranty	III	MC
C26	Terms of warranty of the manufacturer	III	MC
C27	Relationship with vehicle manufacturer	III	TC, MC, EE
C28	Vehicle exterior appearance	I	TC, EE
C29	Vehicle comfort	I	TC, MC, EE

Criteria	Name	Group*	Impact**
C30	Vehicle interior appearance	I	TC, MC, EE

** I – Constructional criteria; II – Initial vehicle procurement costs; III – Vehicle operation criteria; IV – Post operation criteria*
*** TC – Transport costs; MC – Maintenance costs; EE – Energy efficiency*

Also, the impact of criteria on transport costs / maintenance costs / energy efficiency is illustrated on figure 2.

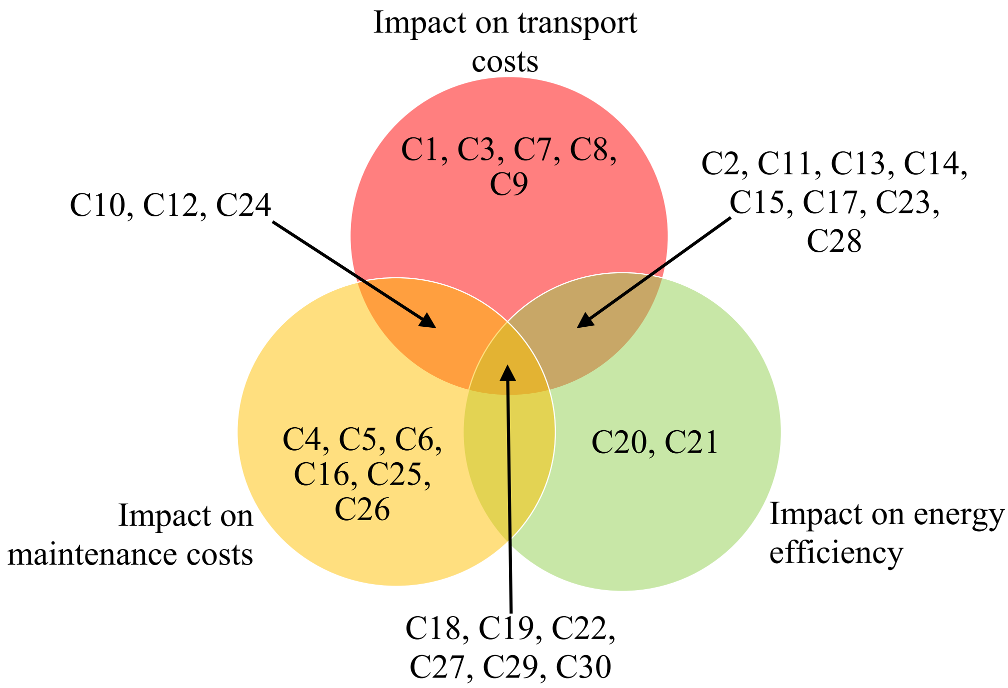

Fig. 2.
Criteria impact on transport costs / maintenance costs / energy efficiency

It is necessary to briefly explain that the criteria such as „vehicle comfort“ and „vehicle interior appearance“ has impact on driver and driver has impact on fuel consumption and if fuel consumption is increased, the energy efficiency is decreased due to emissions. Also, if the vehicle is not comfortable it can cause a driver fatigue and thus traffic accident. Traffic accidents are closely connected to vehicle maintenance costs, as well to insurance costs. Besides before mentioned criteria, we should briefly explain „vehicle exterior appearance“ criterion. This criterion has impact on transport costs and energy efficiency. For example if vehicle has spoilers, the aerodynamics of the vehicle is improved and therefore fuel consumption and emissions are reduced and energy efficiency is enhanced.

Satisfaction with the provided service quality / vehicle quality / spare parts quality are considered under „Good previous experience with the vehicle manufacturer“ criterion, also under criterion named „Relationship with vehicle manufacturer“ good customer support and coverage of service centers are considered.

Since the criteria do not have the same importance, it is necessary for managers to rank the criteria by relevance, in order to make the best decision during the vehicle procurement process. One of the possible ways to evaluate the criteria and to choose most appropriate vehicle is to apply one of the methods of multi-criteria decision making. The first step before applying one of the multi-criteria decision making methods involves evaluating the criteria by the experts, which is the result of this paper. In this regard, the authors of this paper carried out a survey among experts from transport and logistics companies, that included the evaluation of the observed criteria. The description of the conducted survey and the obtained results are presented in the next chapter.

4. Criteria Evaluation

This chapter provides a description of the conducted research in order to collect data about vehicle procurement criteria evaluation, as well as the obtained results.

4.1. Research Description

In June 2018 an anonymous online survey entitled „Vehicle procurement criteria“ was conducted. The survey included 23 experts in this field (professor and assistant from the Faculty of Transport and Traffic Engineering, University of Belgrade, who work in this area, as well as employees from several transport and logistics companies from the Republic of Serbia). Also, 22 students from the mentioned faculty (department for road and urban transport) were included in the survey. All students that participated in survey are final year of basic academic studies and have attended all courses envisaged by this level of study. Although, it is important to mention that students can not be observed on the same way as experts from transport and logistics companies, but the aim of their participation was to find out the differences in attitudes about the relevance of the observed criteria in relation to the experts.

4.2. Demographic Information

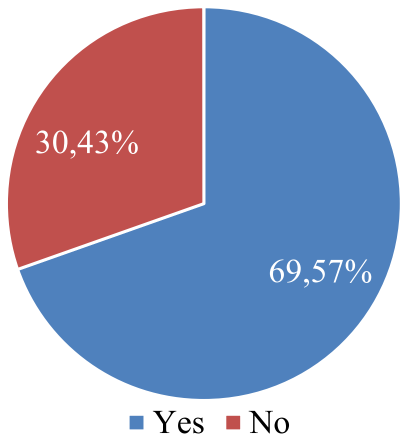
On the basis of experts demografic information, we can see that 91,3% of the male population participated in the survey and only 2 females (8,7%). This is not suprising due to the business activity of the observed companies (transport and logistics) where in the most cases are men employed. Regarding the age structure, the respondents aged between 35 and 44 years (52.2%) and respondents between the ages of 25 and 34 (30.4%) have the dominant participation. Regarding the level of education, it can be seen that the vast majority of respondents have a university degree (63.5%), 21.7% have completed a college, while only one respondent has completed high school and one has PhD.
Of the 22 surveyed students, 63.6% were male respondents, while 36.4% were female respondents. According to the level of studies, it is expected that most respondents are between 18 and 24 years old, and in that sense 19 students belong to that group, and only 3 respondents belong to the group of age from 25 to 34 years. The demographic information of respondents are shown in the Table 2.

Table 2
Respondents demographic information

Demographic information		Experts		Students	
		Frequency	Percentage	Frequency	Percentage
Gender	Male	21	91,3%	14	63,6%
	Female	2	8,7%	8	36,4%
Age	18-24	0	0,0%	19	86,4%
	25-34	7	30,4%	3	13,6%
	35-44	12	52,2%		
	45-54	2	8,7%		
	55-64	2	8,7%		
	65 and above	0	0,0%		
Education level	High School	1	4,4%		
	College	5	21,7%		
	Bachelor of Science	7	30,4%		
	Master of Science	9	39,1%		
	Doctor of Science	1	4,4%		
	Student	0	0,0%	22	100,0%

4.3. Results

In order to determine the validity of the assessment, i.e. experts competence, one of the questions was whether the experts have to deal with vehicle procurement on their job. Out of the 23 interviewed experts, 70% of them stated that they have that obligation, but it should be emphasized that 2 respondents from the Faculty of Transport and Traffic Engineering in Belgrade have declared that they do not have vehicle procurement in their job description, but since they deal with discussed topic, they can be considered as experts and that would increase the mentioned percentage to almost 80%. The vast majority (almost 90% of respondents) stated that when they purchasing a vehicle, they decide to purchase a new vehicle rather than a used one. This is in accordance with the recommendations of some authors. The answers to the above questions are illustrated on Figure 3.



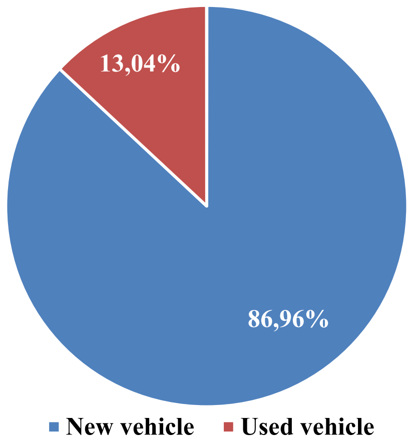


Fig. 3.
Answers to the questions „Is vehicle procurement in your job description?" (left) & „Would you rather buy new or used vehicle?" (right)

The main part of the survey was related to the evaluation of the criteria that are observed during vehicle procurement process. The authors proposed 30 criteria on the basis of literature review, interviews with experts and their own experience. All these criteria are presented in Table 1. (Chapter 3). Besides given criteria, respondents were also given the opportunity to add criteria that they consider as relevant and it is not mentioned. For an easier criteria review, all the criteria will be listed below: 1) vehicle price 2) fuel / energy consumption 3) price of fuel used by the vehicle 4) price of spare parts (for corrective maintenance) 5) preventive maintenance costs (services) 6) maintenance costs during the warranty period 7) discounts that can be made when buying a vehicle 8) financial benefits when buying a vehicle (credit / leasing) 9) remaining value of the vehicle when replacing (reselling) 10) construction characteristics of the vehicle 11) compliance with transport requirements (type and quantity of cargo / type and volume of load compartment) 12) compatibility with existing vehicle fleet 13) useful vehicle capacity 14) engine power / torque 15) tank / battery capacity 16) existence of on-board security systems 17) possession of cruise control 18) vehicle condition – mileage, age 19) type of drive (conventional, alternative, hybrid, electric) 20) air pollution caused by vehicle 21) noise caused by the vehicle during operation 22) possibility to rebuild a vehicle to use an alternative drive 23) possibility to recycle parts and the vehicle after use 24) good previous experience with the vehicle manufacturer 25) duration of manufacturer's warranty 26) terms of warranty of the manufacturer 27) relationship with vehicle manufacturer 28) vehicle exterior appearance 29) vehicle comfort 30) vehicle interior appearance.
The average grades given by experts and students for each of the above mentioned criterion are graphically shown on Figure 4.
As can be seen from the Figure 4, experts gave higher grades to most criteria, i.e. they consider them more important than students do. In this sense the overall average grade for all observed criteria which was given by the experts was 7.01, while the students gave an overall average grade of 6.57. It is important to emphasize that there are no significant differences in the estimates of the criteria between these two populations. The criterion that has the highest difference in the average grade obtained by experts or students is the criterion entitled "Vehicle maintenance costs during the warranty period", where experts evaluated this criterion for 2.02 grades more than students did. Visible differences (difference from 1 to 2 grades) can be seen for the criteria such as the price of fuel used by the vehicle, the price of spare parts (for corrective maintenance), the preventive maintenance cost (services), the construction characteristics of the vehicle, the possession of cruise control.
It is very interesting to note that besides the subjects related to energy efficiency and reduction of environmental pollution caused by road transport, students had less ecological awareness than experts, and therefore criteria such as air pollution caused by vehicle and noise caused by the vehicle during operation, are considerably lower graded. On the other hand, students gave greater importance to criteria such as vehicle exterior appearance, vehicle comfort, vehicle interior appearance. Based on this, a certain level of inexperience among students may be seen and due to that it is justified because these two groups of respondents (experts and students) are separated.
The first five most important criteria from the point of view of the experts are: 1) compliance with transport requirements (type and quantity of cargo / type and volume of load compartment), 2) fuel / energy consumption, 3) preventive maintenance costs (services), 4) spare parts price (for corrective maintenance), 5) vehicle condition – mileage and age. On the other side, the first five most important criteria from the point of view of the students are: 1) fuel / energy consumption, 2) vehicle condition – mileage, age, 3) vehicle price, 4) compliance with transport requirements (type and quantity of cargo / type and volume of load compartment) and 5) vehicle comfort.

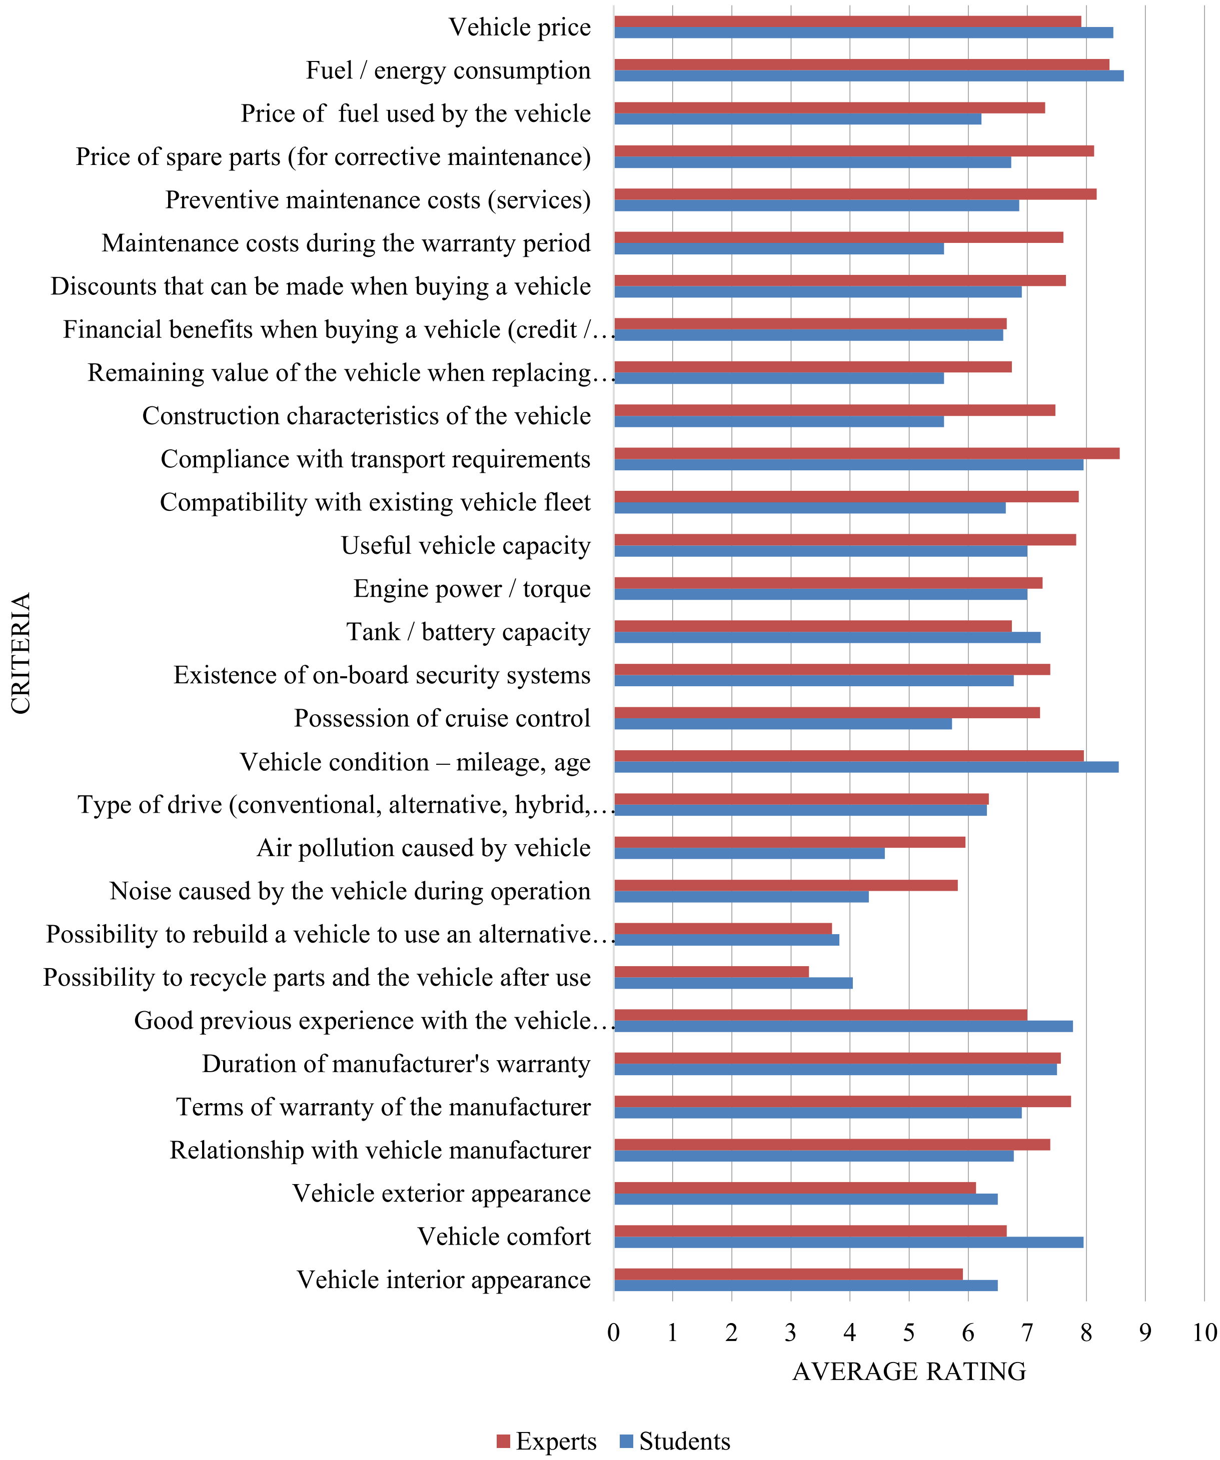

Fig. 4.
Average grades given by experts and students for each criterion

The second part of the questionnaire was dedicated to vehicles with an alternative type of drive (alternative fuel vehicles). Respondents were asked whether they thought about purchasing alternative-fuel vehicles, of which 60% of the experts answered negatively, while 40% said they thought about purchasing these vehicles. This is graphically illustrated on Figure 5.

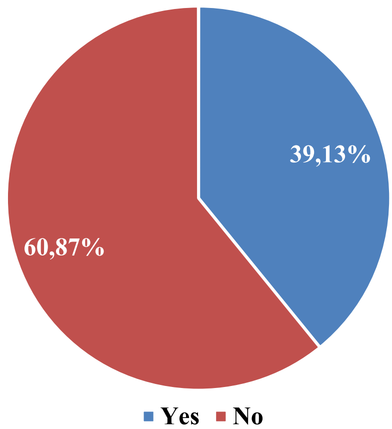

Fig. 5.
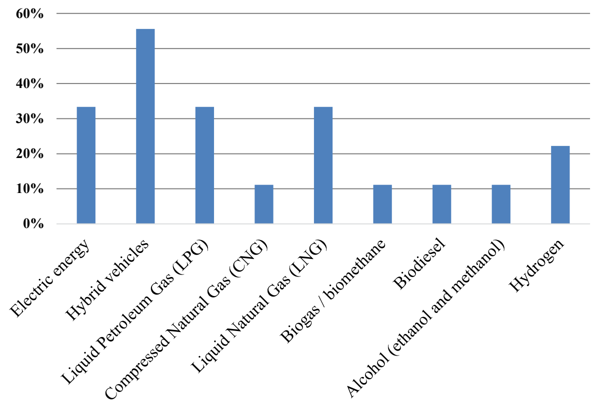
Respondents' answers to the question „Did you think about alternative-fuel vehicles procurement?“

If the respondents answered positively to the previous question, they were asked an additional question which alternative propulsion they were thinking about. On this question, the respondents could give more answers, and therefore the percentage sum of the answers shown in Figure 6 (left) is greater than 100%. In this regard, the majority of respondents said that they thought about hybrid vehicles (> 50%), while the vehicles with propulsion on the liquefied petroleum gas and liquefied natural gas, as well as electric vehicles were observed in a slightly smaller percentage (about 30%). The compressed natural gas, biogas, biodiesel and alcohol (ethanol and methanol) are propulsions that cause the least interest among respondents (about 10%). (Figure 6 - left)
On the other hand respondents that didn’t think about alternative-fuel vehicles procurement were asked a question what is the main reason why they didn’t consider this type of vehicles. As they stated, the main reasons are insufficiently developed infrastructure of the alternative fuel stations, as well as high price of alternative-fuel vehicles. (Figure 6 - right)



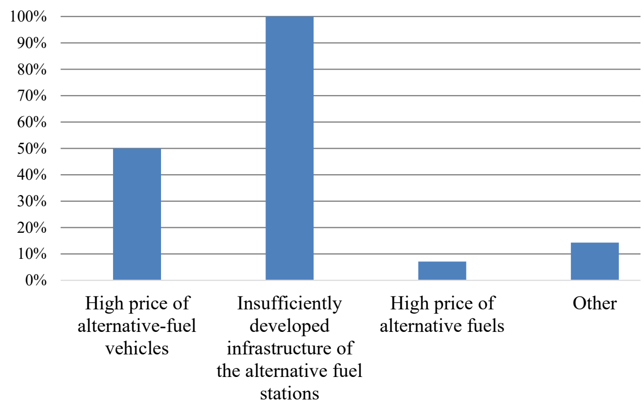


Fig. 6.
Answers to the questions which alternative propulsion you were thinking about (left) and what is the main reason because you didn’t consider alternative-fuel vehicles (right)

5. Conclusion

This paper examines the criteria on which companies owning their own fleet can successfully carry out the vehicle procurement process and fleet renewal fleet. By choosing an appropriate vehicle, the company reduces its transport and maintenance costs on the one hand, and increases fleet’s energy efficiency on the other hand and thereby increase its profit and competitiveness on the market. The authors conducted an anonymous online survey entitled „Vehicle procurement criteria“, which included 23 experts in this field and 22 students from the Faculty of Transport and Traffic Engineering, University of Belgrade – department for road and urban transport. The 70% of analized experts in their job have already participated in the vehicle procurement process. The experts and students evaluated 30 different criteria which were defined by authors on the basis of literature review, interviews with experts and their own experience. Experts’ and students’ grades are presented separately in order to see differences in the evaluation of observed criteria.
Overall average grade for all observed criteria which was given by the experts was 7.01, while the students gave an overall average grade of 6.57. "Vehicle maintenance costs during the warranty period", was criterion with highest difference in the average grade obtained by experts and students (experts evaluated this criterion for 2.02 grades more than students did). Also, it is very important to say the students were less ecologically aware. In that sense students

evaluated air pollution and noise caused by vehicle with lower grades than experts. Differences from 1 to 2 grades can be seen for the criteria such as the price of fuel used by the vehicle, the price of spare parts (for corrective maintenance), the preventive maintenance cost (services), the construction characteristics of the vehicle, the possession of cruise control etc. In fact, no significant differences (more than 2 grades) in the evaluation of the criteria were observed, and there are many criteria that are similarly evaluated.

The first five most important criteria from the point of view of the experts ar the point of experts' view are: 1) compliance with transport requirements (type and quantity of cargo / type and volume of load compartment), 2) fuel / energy consumption, 3) preventive maintenance costs (services), 4) spare parts price (for corrective maintenance), 5) vehicle condition – mileage and age. On the other side, the first five most important criteria from the point of students' view are: 1) fuel / energy consumption, 2) vehicle condition – mileage, age, 3) vehicle price, 4) compliance with transport requirements (type and quantity of cargo / type and volume of load compartment) and 5) vehicle comfort.

Also, the authors discussed the experts attitude on alternative-fuel vehicle procurement. As the result of that came that more than 60% of the experts didn't consider procurement of alternative-fuel vehicles, and as two main reasons for that respondents state insufficiently developed infrastructure of the alternative fuel stations, as well as high price of alternative-fuel vehicles.

The subject of further research will be a determination of the criteria relative weights, their interdependence and application of some MCDM methods, as well as concrete example of the successfully applied multi-criteria decision making method in vehicle procurement process in one or more transport and logistics companies in the Republic of Serbia.

Acknowledgements

The research in this paper has been realised within the project TR36027 named: "Software development and national database for strategic management and development of transportation means and infrastructure in road, rail, air and inland waterways transport using the European transport network models" supported by the Ministry of Science and Technological Development of the Republic of Serbia.

Abstract: Lately, the significance of aerodynamics in the modern vehicle manufacturing sector has grown increasingly. With the increasing popularity of sports cars, the shape of their body, elements and wings, which determine air resistance and compressive forces, play an important role. The Article analyzes aerodynamic properties of a "Formula Student" car and their impact on the body shape. The designed "Formula Student" sports car body prototype allowed designing the exact car model using sculptural plasticine, which was tested in the aerodynamic tube. Results of experimental tests in wind tunnel: air resistance force dependence on air flow speed and downforce dependence on air flow speed also were presented.

Keywords: Aerodynamics, vehicle, Formula Student, prototype, calculations.

1. Introduction

"Formula Student" competitions are known and organized all over the world, which bring together teams of students from different countries who design, test and race with "Formula Student" cars made by themselves. As students compete, safety during the race is the key aspect. "Formula Student" cars are made following strict technical requirements defined in instructions, which indicate the critical points of the frame construction, engine limitations, requirements for the body and many other parameters. However, as in other automobile sports, it has always been attempted to maximize the dynamics of the car and reach the best possible lap time. To achieve this, there have been used two-way modifications: improving the engine or an automobile's aerodynamic elements. As the construction uses sports motorcycle engines which generates 70 – 80 kW or even more power, even having installed the mandatory calibrated restrictor in the intake manifold, they remain competitive. Therefore, in order to improve race car lap time, much attention should be paid to the car's aerodynamic qualities.

A suitable aerodynamic package can increase the car's downforce. (Mariani *et al.,* 2015) performed a numerical CFD/3D "Formula Student" automobile modelling with and without the front spoiler. He found out that driving at 85 km/h speed, the downforce of the automobile without the front spoiler is 1226.8 N/1376.0 N for the front/rear axis correspondingly. Having fixed the spoiler, the downforce of front wheels increased to 1499.2 N, though the downforce of rear wheels reduced to 1274 N. Overall downforce of the car increased by 170.4 N (Mariani *et al.,* 2015). With the increased downforce, the car can pass the racetrack corners faster, but in order to achieve the maximum speed and lose as little power as possible, it is necessary to reduce the air resistance. In order to achieve this, both standard and sports car producers try to reduce the air resistance coefficient. (Hetawal *et al.,* 2014) performed a numerical "Formula Student" automobile modelling using ANSYS programme. Three different automobile configurations were chosen for modelling and it was examined how the counterflow stream increases pressure to the car body and aerodynamic details (Fig. 1).

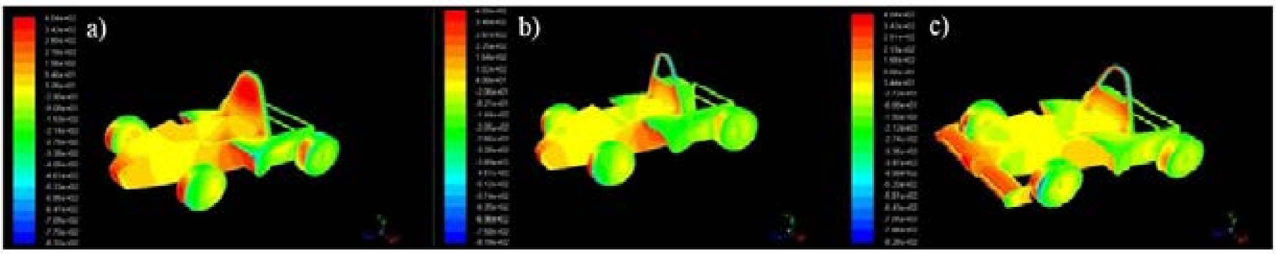

Fig. 1.
"Formula Student" automobile models affected by the counterflow stream pressure to the car body and aerodynamic details: a) with a closed firewall; b) with a partly-opened firewall; c) with a front spoiler
Source: (Hetawal et al., 2014)

It was found out that the model's with a closed firewall air resistance coefficient is 0.85. Having modified the firewall, the air resistance coefficient has dropped to 0.75, and to 0.7 with the additionally installed front spoiler (Hetawal *et al.,* 2014). When designing "Formula Student" cars, other aerodynamic elements have been added, such as underbody tunnels or the rear spoiler. This increases the downforce of the car and reducing the air resistance coefficient. (Dharmawan *et al.,* 2018) performed a numerical "Formula Student" car modelling using the AUTODESK FLOW DESIGN programme with the front and rear spoilers being mounted. The gained results were compared with the modelling data without using aerodynamic elements. It was found out that having mounted the front and rear spoilers,

[4] Corresponding author: j.matijosius@vtdko.lt

the lower air pressure is generated to the car‘s front, also the direct streamline flow is formed, which covers up the car and redirects the opposite air flow. Due to these changes, the air resistance coefficient has reduced about 23% from 0.728 to 0.560 (Dharmawan *et al.,* 2018).
Although the air resistance force is often determined using various computer simulation programmes, it is necessary to validate the gained data with the real test results. The most commonly used is one of three types of wind tunnels (Tavoularis, 2005), which can be used to test the objects of a real size or scale models with appropriate proportions.

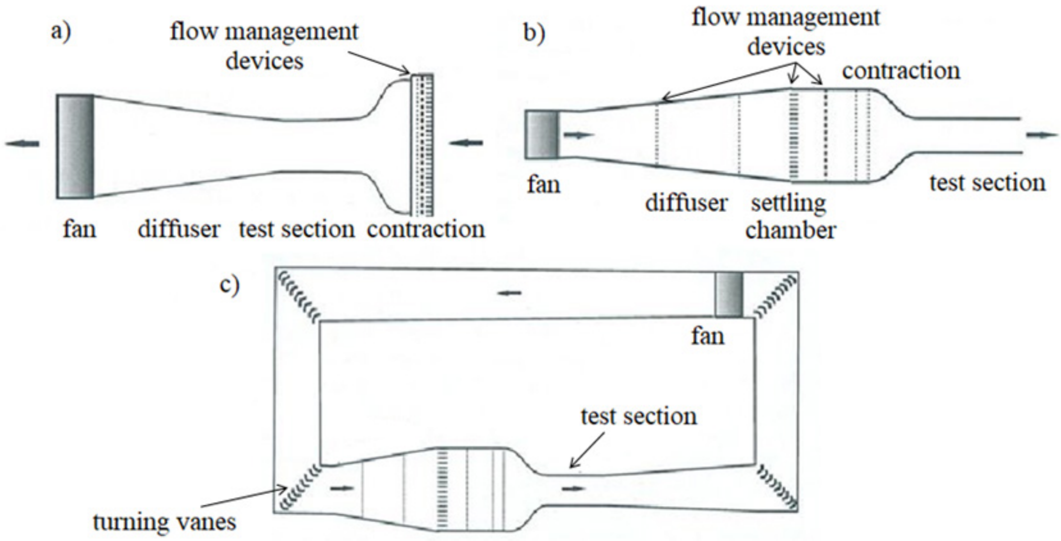

Fig. 2.
Types of wind tunnels: a) Suction wind tunnel; b) Blowdown wind tunnel; c) Closed-circuit wind tunnel
Source: (Tavoularis, 2005)

(Hammond and Flay, 2008) performed tests of the twice reduced "Formula Student" model in the suction type wind tunnel. Rolling road facility was also used for the tests, ensuring the real conditions of experiment. The tests were performed regulating the front and rear spoilers' angle of attack and changing the air flow rate from 10 to 15 m/s. It has been determined that changing only the angle of attack, the car's air resistance coefficient varies from 0.9 to 1.1 and the weight distribution between the front and rear axles has changed from 43% from the front and 57% for the rear to 33% and 67% correspondingly (Hammond and Flay, 2008).

2. "Formula Student" Model New Body Designing

During the designing stage of "Formula Student" there have been done frame construction, reduced by a scale of 1:10, on which the body shape is modelled using sculptural plasticine.

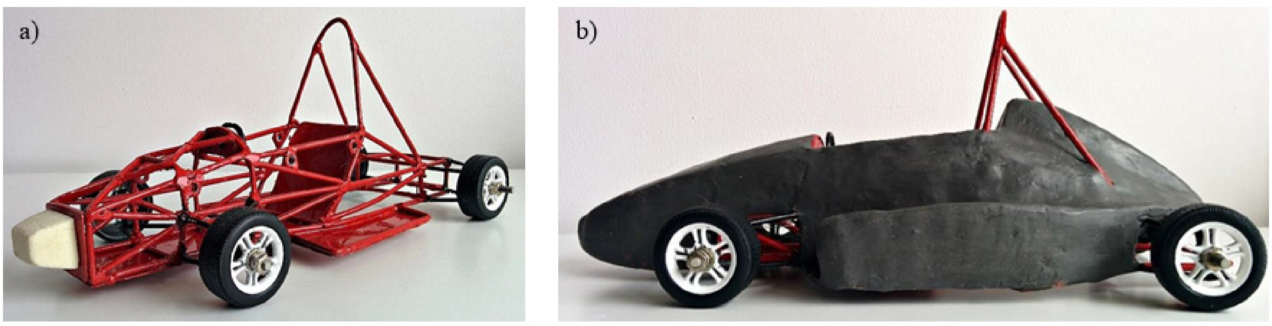

Fig. 3.
"Formula Student" model: a) – framework construction; b) – modelled body

At the start of the modelling stage, the following principles were implemented:
- The model body should be as close as possible to "the form of a drop", looking from the side because "the drop" form is the most streamlined form known in nature (Katz, 1995).
- Vacuum zone filling. The largest vacuum occurs at the rear of the car. In the case of the "Formula Student" model, vacuum occurs at the rear of the car and behind the driver's seat. The following solutions are chosen to reduce these aerodynamic phenomena:

- When modelling the cars body engine cover is created, which would fulfil the vacuum zone behind the driver's seat.
- The rear spoiler.
- For the emerging vacuum at the rear of the model, a solution is chosen – sidepods are modelled, which would lead the air flow to the back of the model thus reducing the occurrence of air deflection phenomena.

Generation of downforce. For the body, one of the most important priorities is to generate more downforce without increasing air resistance. The sidepods are one of the most important body elements, which aim at reducing the vacuum zones at the rear of the car and generate the additional downforce. Air intake cavities are also designed to provide additional function of air flow for an engine and exhaust system cooling. The sidepods are designed of a special form, with a rising angle, viewed from an air intake cavity to the rear side. It is this form which will generate the downforce.

The front body part. When modelling the front part, attempts are made to make the form as closely as possible to the frame construction, but also considering the angle of attack, which will create the downforce at the front body part.

3. Digital Designing of "Formula Student" Model New Body

In the programme "SolidWorks" there have been modelled separate elements on the framework construction. Digital designing consists of the following stages:
- The front body part on the framework construction (Fig. 4., a).
- Front body, sidepods and engine cover on the framework construction (Fig. 4., b).

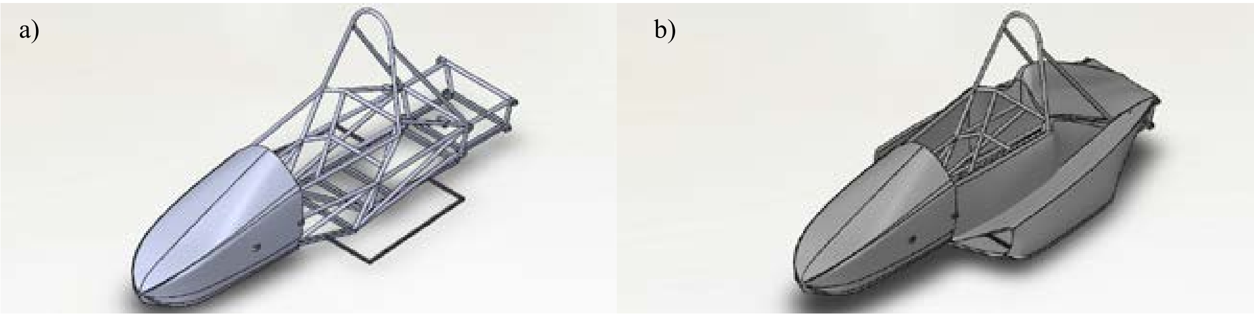

Fig. 4.
Stages of the body parts modelling

When modelling the front body part (Fig.5., a), the following aspects were taken into consideration:
1. *Form*. Attempts were made to make it as streamlined as possible and as closely as possible to the frame construction.
2. *Angles.* Considering the official requirements of the "Formula Student", sharp corners at the front of the body or other protruding parts are prohibited. All forward sides of the body that can injure a person must be rounded in at least 38 mm. radius (Committee, 2016). Because the designed body is 10 times smaller than the real one, the front radius cannot be smaller than 3.8 mm. The radius of the designed body in the horizontal axis is 5 mm, in the vertical axis it is 8 mm.
3. *Profile corner of the form (attack corner).* The corner between the lower and upper surface parts was kept 20º. At a larger angle, a higher downforce is created in the front part of the body, but the air resistance is increased accordingly. As a result, the chosen angle is a kept balance between the resistance and downforce.
4. *Thickness.* The thickness of a detail's side is designed to be 2 mm, because this thickness part can be considered a rigid surface. It was tried to keep the detail surface area as small as possible because otherwise the resistance force would increase. When choosing the thickness it was also considered that the manufactured part will be processed till finishing stage.
5. *Dimensions.* After designing the front body part, the following dimensions were obtained: length 104 mm, width 55 mm and height 62 mm.

When designing the engine cover, the main aspect was form. The aim was to eliminate the vacuum zone, appearing at the car's rear part and behind the driver's seat. The detail is attempted to be designed as much similar to the form of a drop as possible, improving its streamline form. The rear body part also reduces turbulence at the rear.
The dimensions of the rear body part are the following: length 89 mm, width 54 mm and height 51 mm.
When designing the sidepods (Fig. 5., b), the following aspects were considered:
1. *Form*. To keep it as close as possible to the framework construction, but also as streamlined as possible.
2. *Sidepods angle*. 12 degrees corner is kept. The following functions are performed:
   - Generated downforce;
   - Air flow direction;
   - Cooling.

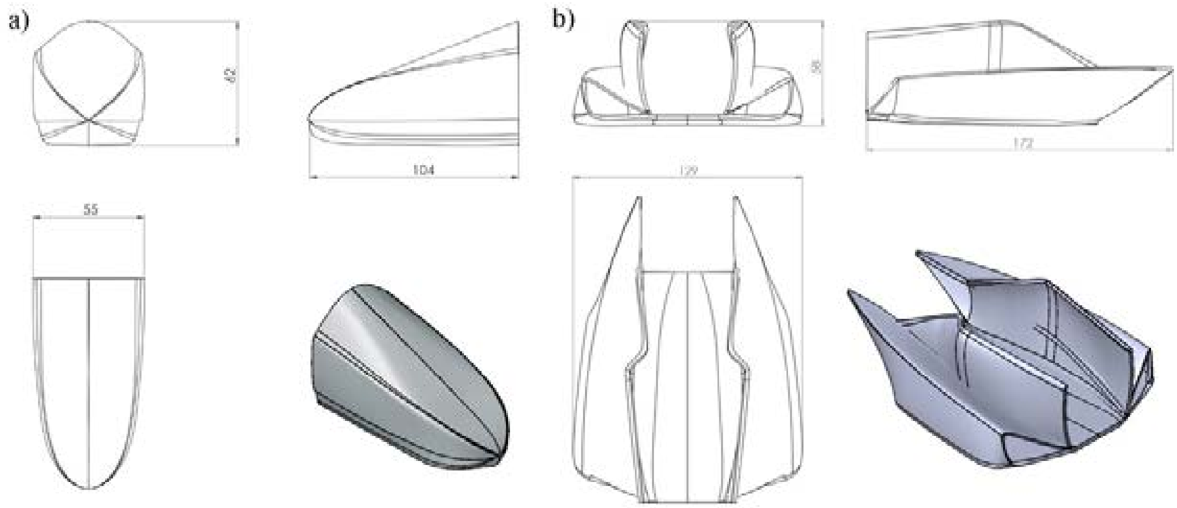

Fig. 5.
Aerodynamic parts designing: a) – front body part; b) – sidepods

The new body was made and mounted on “Formula Student“ model. Using experimental tests in the wind tunnel, there were determined air resistant and downforce in sports car “Formula Student” model: without the body (Fig. 6., a), with the old body No.1 (Fig. 6., b) and with the newly designed body No.2. (Fig. 6., c). The measuring equipment provides the data in grams (g), which are converted into force (N). In every case, the air resistance coefficient has been calculated and the comparative analysis of data has been performed.

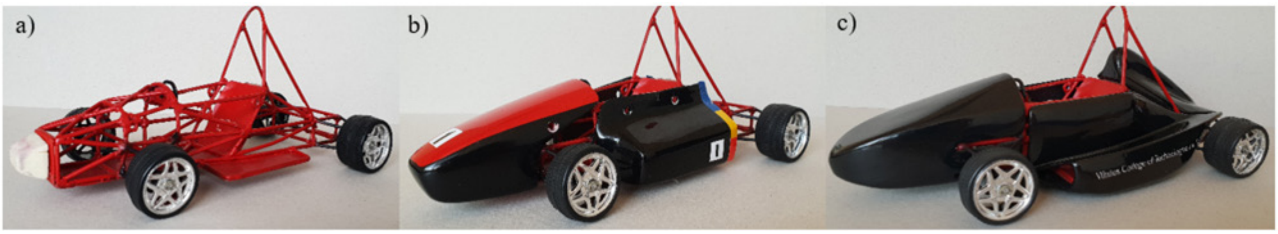

Fig. 6.
“Formula Student“ model prepared for measurement in wind tunnel: a) – without the body; b) – with old body; c) – with new designed body

4. “Formula Student“ Model Air Resistance Coefficient Establishment Methodology

“Formula Student“ model aerodynamic force research has been performed in the suction type wind tunnel (Fig. 7) with different variations of the model: without the body, with the body No.1 and with the newly designed body No.2. During the experiment the following aspects affecting the researched sports model were measured: air resistance force (D, N), downforce (D_{df}, N), air flow speed (U, m/s), and air temperature (T_{air}, °C).

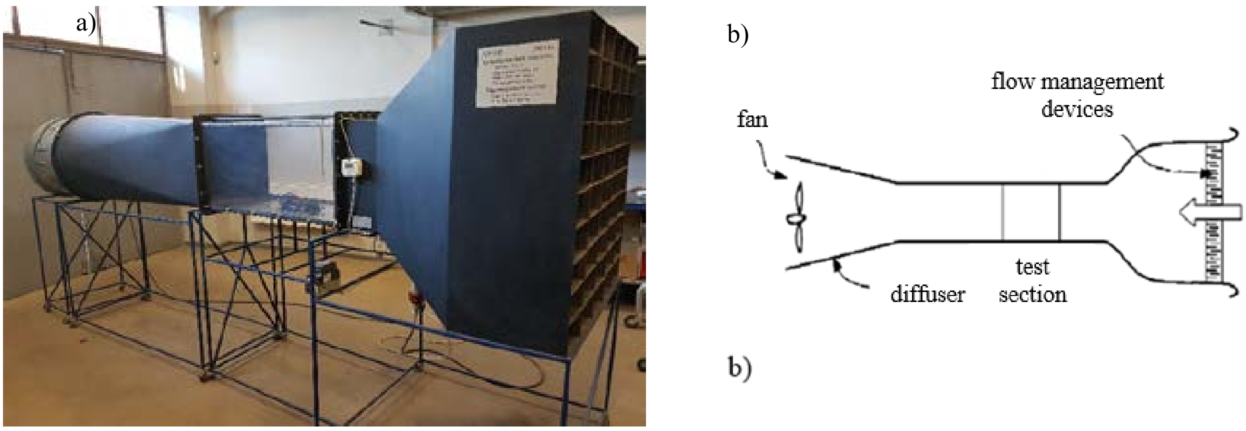

Fig. 7.
Suction type wind tunnel: a) –wind tunnel for research; b) – schematic view of wind tunnel

In the wind tunnel, the air flow has been created by the installed electric fan, operated by the frequency converter from 10 to 60 Hz. The air flow speed and temperature have been measured by the installed anemometer (measuring values 0 – 30 m/s, accuracy 3%) in the test chamber.
The drag coefficient (C_D), which quantifies the aerodynamic sleekness of the vehicle configuration (Katz, 2016):

$$C_D = \frac{D}{0.5\rho U^2 S};$$

where: D – air resistance force, N;
ρ – air density, kg/m^3;
U – air flow speed, m/s;
S – frontal area of vehicle, m^2.

The frontal area of vehicle model without body parts $S = 0.005$ m^2; with mounted old body (No.1) $S = 0.006$ m^2; with new body (No.2) $S = 0.0058$ m^2.

5. Results and Discussion

The graphs (Fig. 8) show the air resistance and downforce values measured during the tests. The biggest air resistance force in all values of speed appear in the model without the body. With the body No.1, the air resistance force has reduced by ~9,5%, with the newly designed body No.2 it has reduced by ~40%.
Such a dramatic change in forces was determined by the shape and size of body parts (Fig. 4., b). Increasing the angle of attack of the front part, the downforce becomes bigger, though the air resistance also increases correspondingly. When selecting the angle of attack of 20º, the balance between air resistance force and downforce is kept.

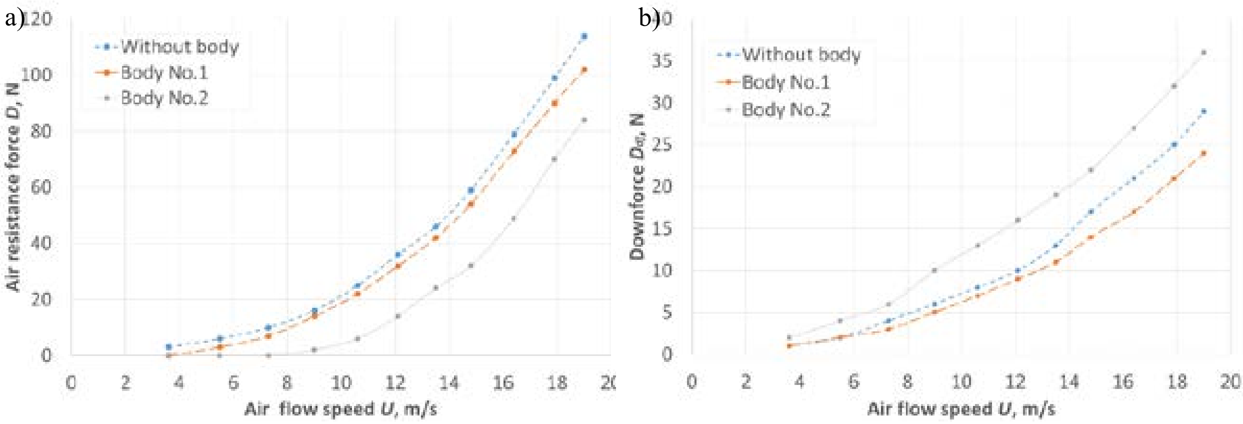

Fig. 8.
Results of experimental tests in wind tunnel: a) – air resistance force dependence on air flow speed; b) – downforce dependence on air flow speed

Having compared the downforce with the body No.1 and without the body, it has been established that the force reduces by ~16%, with the newly designed body No.2, the compression force increases by 31%. This was largely due to the shape of the front and sidepods angles of attack and the surface area. The mounting of the engine cover reduces the vaccum zone emerging in the rear part of the “Formula Student“ and also reduces the air turbulence. Having calculated the air resistance coefficient, it has been determined that for the model without a body: $C_D = 0.874$; with the body No.1 $C_D = 0.683$; with the body No.2 $C_D = 0.434$.

6. Conclusions

The experimental study of the aerodynamic forces of the “Formula Student“ model revealed that the largest air resistance force in the examined speed range was obtained studying the model without the body where the calculated drag coefficient was $C_D \approx 0.87$. Having applied the old body No.1, the air resistance force reduced by ~9,5%, drag coefficient reduced by ~21%. Having improved the front, sidepods and mounting the engine cover, air resistance force reduced by ~40%, drag coefficient reduced by ~50%, which is $C_D \approx 0.43$.
Comparison of the forces affecting the model without the body and the old body reveals that the downforce has reduced by ~16%. Upgrading of the front, sidepods and mounting the engine cover, increased the downforce by 31%. Mounting of the engine cover reduces the vacuum zone appearing at the rear of the “Formula Student“, also reduces the air turbulence.

Abstract: The article describes the results of environmental impact research on the degradation of rubber spare parts and their chemical-mechanical properties when used in transport vehicles with regard to financial costs in the field of logistics. Samples were exposed and measured at different temperatures, simulating outdoor temperatures that affect the material and thus affect its life. It provides the results of thermogravimetric analysis, material characteristics of plastic deformation and shore hardness measurement of polymer material used in the spare part of the transport vehicle (Billingham, 2007; Binar et al., 2018). The samples used conform to ISO 76-19-1 (ISO, 2010) and ČSN 62 1522 (ČSN, 1993). Based on the research, recommendations are made on optimal conditions for the storage and use of materials (Cheng, 2013).

Keywords: thermogravimetric analysis, plastic deformation, Shore hardness, polymeric material, transport vehicle, thermo-oxidative ageing.

1. Introduction

Polymeric materials are used in spare parts of the means of transport. Exposure to environmental conditions (e.g. Temperature, Oxygen, UV radiation) occurs in decomposition processes, resulting in accelerated aging of the material (Billingham 2007). In the field of vehicle operation, an increased incidence of damage to polymeric materials on rubber bellows has been identified, which protects the connections at constant speeds from external impurities. As a result of the damage, the active parts of the constant speed connections are irreversibly worn by external impurities resulting in their destruction and subsequent repair. As a result, the vehicle becomes inoperable and unable to perform the required tasks. Given that road transport is an integral part of global transport, this is a serious problem.
The aim of this paper is to explain how the chemical-mechanical properties of polymeric materials from which the polymer is made are influenced by ambient temperatures and thermo-oxidative aging.
Another objective was to carry out basic research to find and confirm the composition and basic mechanical properties of the disc on both sides, both inside and outside.

2. Materials and Methods

For the purpose of assessing the properties of polymeric material used in rubber waves to protect the constant speed couplings in vehicles, new and old bellows were used to allow a more accurate assessment of the influence of ambient temperature and thermo-oxidative aging on the cycle life of the polymeric material below.
The filler / reinforcement contents and temperature stability of the test material were tested using thermogravimetric analysis using Q500, TA Instruments.
Temperature stability and filler content, including carbon black, were determined in all samples from the decomposition curve. The temperature program differed due to different types of polymeric materials and filler content. The defect samples were heated under an inert atmosphere of nitrogen (60 ml/min), from room temperature to 550 °C at 10 °C/min, then cooled to 300 °C at 10 °C/min and then the atmosphere was switched to air followed by heating to 750 °C at a rate of 10 °C/min. The other samples (10.9 to 18.8 mg) were heated under an inert atmosphere of nitrogen (60 ml/min) from room temperature to 750 °C at 10 °C/min, then the atmosphere was transferred to air and held for 5 minutes.
Shore hardness was determined by measuring the physical and mechanical parameters of materials in accordance with ISO 7619-1 (ISO 2010, Kazda 2015). Samples were measured by Shore A for 15 seconds (ShA15). The measured location was determined 12 mm from the edge of the measured body. The final value is the arithmetic mean of the 5 measurements that have been given at positions of at least 5 mm. Measurements were made on samples after simulation of "winter" thermo-oxidative degradation at -15 °C/-20 °C and "in summer" at + 30 °C/+ 35 °C (Taweepreda et al. 2013).

3. Results and Discussion

3.1. Mechanical Properties

The chemical-mechanical properties of the polymer material were based on tensile testing using a 10 kN Shimadzu AGS-G test machine or 250 kN Dartec test machine at a specific test speed. Specific condition measurements (machine type, test speed) were maintained throughout the accelerated aging of the sample. The bodies for this evaluation were

[1] Corresponding author: tomas.binar@unob.cz

cut out of the bladders of the truck used between and outside to avoid the homokinetic joint from environment impurities.
Characteristic parameters of bellow tensile properties were selected as follows: tensile strength (TS), which equals the tensile strength at break (TS_b) for the rubbers in the experiment, elongation at break (E_b), which characterizes the elongation of a specimen at break, and tensile stress at 200% elongation, which is referred to as 200% modulus in this experiment (Ehrenstein, 2004).

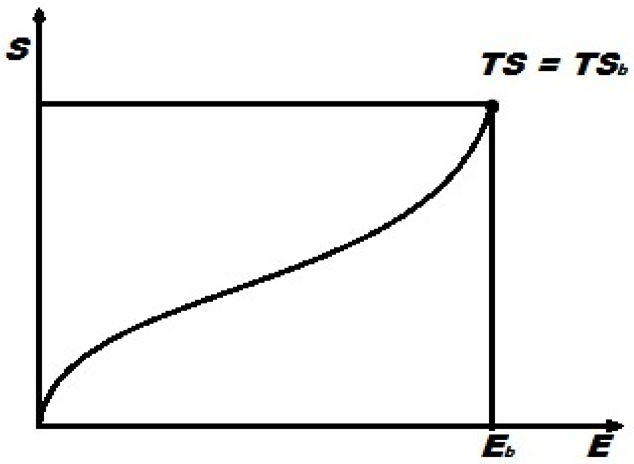

Fig.1.
The shape of the tensile curve characteristic of the rubber tested: S- tensile stree, E- percentage elongation, E_b - elongation at break, TS- tensile strength, TS_b - tensile strength at break

The polymer bellow specimens were exposed to accelerated thermo-oxidative ageing at temperatures -15°C/-20°C simulating a "winter" and temperatures +30°C/+35°C simulating a "summer"; the temperatures were set according to standard ČSN 62 1522 (ČSN 1993).

4. Results and Discussion

4.1. Thermogravimetric Analysis (TGA)

Different types of polymeric materials tested were shown by different distribution curves as shown in Figure 1. The curves are almost identical for the type-new-new type-internal-new rubber bellows material that was decomposed in two decomposition steps at temperatures of about 390 and 620°C (Ti, the fastest material loss temperature) and the greatest material loss (92%) occurred at 390°C. Weight loss approx. 0.2% below 150°C is attributed to volatile events, most likely humidity. All materials were completely decomposed under an inert atmosphere of nitrogen. Within the scope of this TGA article, the same composition of all observed bladder samples was confirmed (Cheng et al., 2016).

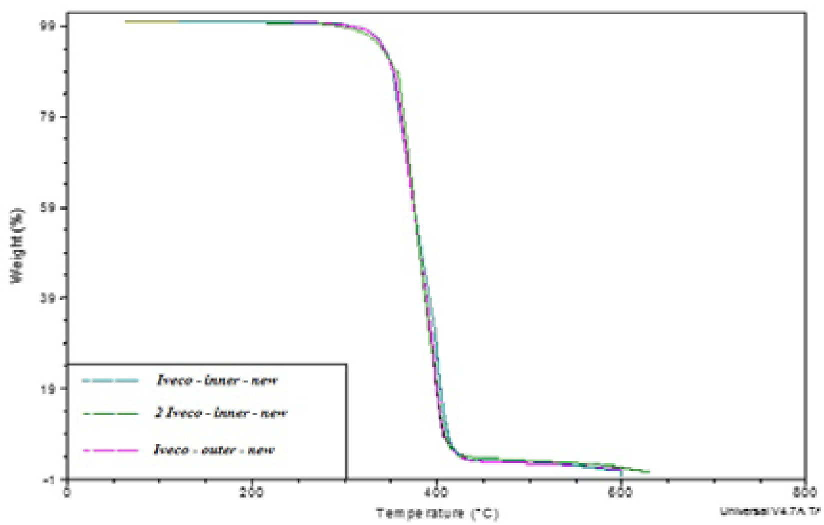

Fig. 2.
Decomposition curves of polymeric materials

4.2. Shore A Hardness Measurement

Shore A hardness was measured in rubber waves every 15 s. Only a limited number of samples were made due to the conical and wavy bellows shape; therefore their hardness was measured only after the tensile test, when the samples were stretched and deformed. Hardness values are therefore approximate.
In the following Tables 1 and 2, the hardness test results for rubber bellows are given after exposure to winter and summer simulating temperatures.

Table 1
Shore A hardness measured every 15 s in samples made from the original outer bellows after accelerated thermo-oxidation aging at -15 ° C / -20 ° C simulating "winters" and temperatures + 30 ° C / + 35 ° C simulating "summer"

Bellow-outer	**Shore A hardness – 15s**			
	Length of exposure in simul. years	**0 years**	**1 year**	**2 years**

3.4. Evaluation of Mechanical Properties

The plastic deformation of the polymeric material of Iveco rubber bellows was tensile tested. The tensile strength R_m [MPa] and modulus of elasticity E [MPa] characteristics measured are stated in Tables III. and IV.

Table 3
Tensile test results – Rubber bellow – outer

Rubber bellow- outer						
Length of exposure in simul. years	0		1		2	
Mechanical properties	R_m[MPa]	E [MPa]	R_m [MPa]	E [MPa]	R_m [MPa]	E [MPa]
-15°C/-20°C“winter”	19.82	1.0	20.58	1.1	17.42	1.2
+30°C/+35°C“summer”	19.94	1.0	21.25	2.4	19.10	2.3

Table 4
Tensile test results – Rubber bellow - inter

Rubber bellow- inter						
Length of exposure in simul. years	0		1		2	
Mechanical properties	R_m [MPa]	E [MPa]	R_m [MPa]	E [MPa]	R_m [MPa]	E [MPa]
-15°C/-20°C “winter”	20.51	1.3	21.98	1.0	22.01	1.2
+30°C/+35°C summer”	20.85	1.3	23.01	2.7	18.29	2.5

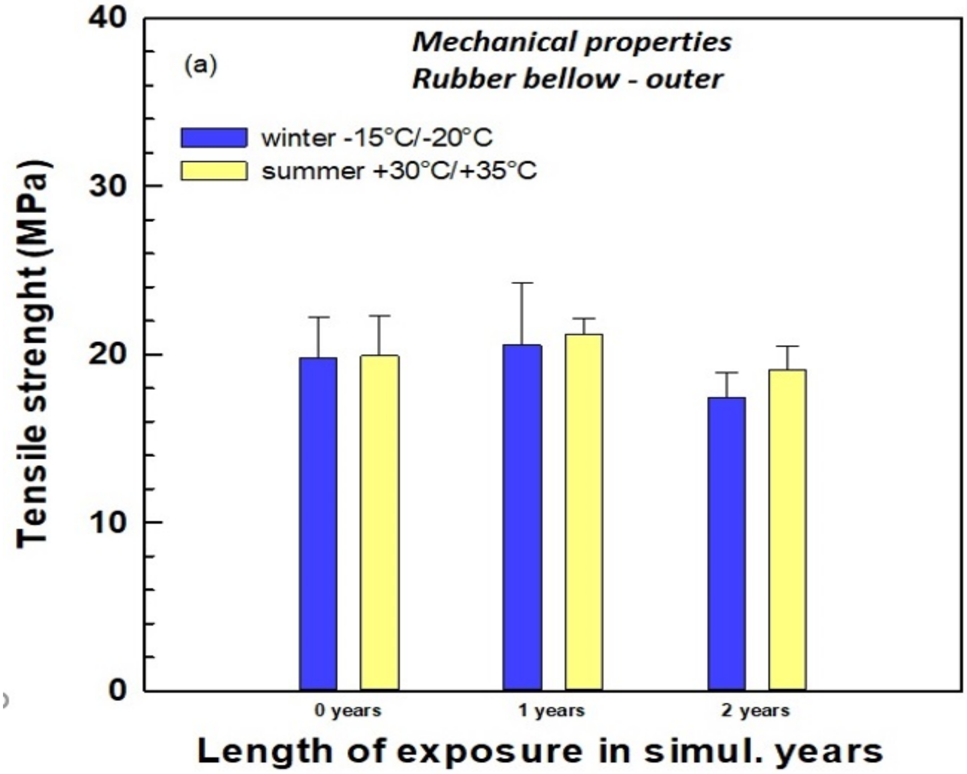

Fig. 5.
Tensile test ofRubberbellow (a) outer

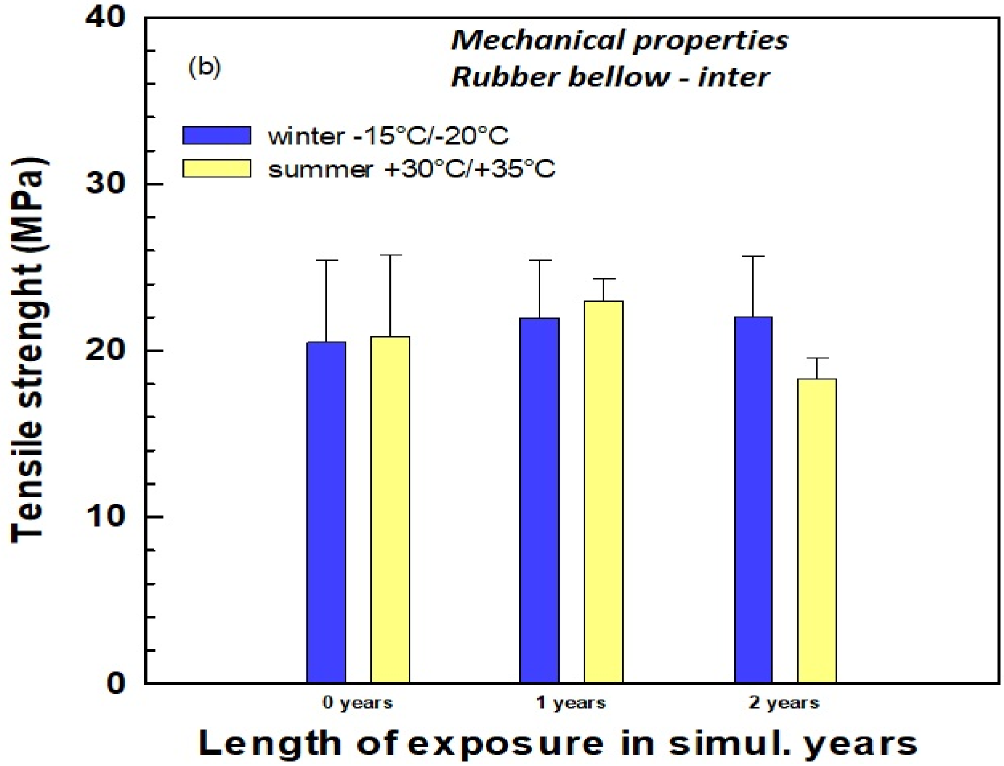

Fig. 6.
Tensile test ofRubberbellow (b) inter

Based on the results obtained, it can be stated that the results of measuring the mechanical properties are in accordance with the hardness measurement. In case of part a) - external, it can be stated that at the winter temperature, the hardness values are slightly increased and the tensile strength decreases slightly. The level depends on the length of exposure.
At summer temperature, hardness expands significantly after the first year of use and exposure and continues to grow. Tensile strength decreases and it can be assumed that the elongation at higher temperature will be significantly higher compared to winter conditions (Samsuri, 2010).

In the case of part b) - inter, the behaviour of the samples is the same, both parts are from the same polymer as confirmed. The only difference can be observed in the Shore A hardness assessment, where the "winter" simulation and the subsequent measurement of the samples yielded lower values than in the case of external parts exposed under the same conditions.es then in case of the outer parts exposed at same conditions (Naruse et al., 2012).

5. Conclusion

In winter temperatures, the soft bellows of the lorry are slightly hardened and their tensile strength increases slightly. At summer temperatures, the hardness increases even after the first year of exposure, as does their "bracing" speed, while tensile strength decreases, resulting in early tearing. Chemical analysis has shown that the rubber mat is made of polyester.

Based on the result, it can be stated that their exposure to high and low temperatures for several years brings about the release of their functional characteristics, which lead to continued use of the vehicle to its damage and stops performing its function.

The solution could be, for example, when changing the mixture used in the production of bellows. The second and third variant solutions are the modification of the external part of the chassis - either its parameters or the production technology, or its conditions, in order to prolong the life of the outer bellows, as the damage was mainly caused by them (Vahdati et al., 2005).

INVESTIGATION OF AUTONOMOUS VEHICLES FIT INTO TRADITIONAL TYPE APPROVAL PROCESS

Máté Zöldy [1]
[1] *BME, Department of Automotive Technologies, Budapest, Hungary*

Abstract: To register your car a special document have to be submitted in Europe: Certificate of conformity for new cars. The certificate of conformity is issued by the manufacturer and shows that vehicles technical characteristics meet safety and environmental standards. It can be either a European (EC) or a national certificate. Paper presents the typical type approval processes for traditional cars and summarizes the main questions that should be addressed during the development of type approval process fit for autonomous vehicles.

Keywords: type approval process, autonomous vehicles.

1. Introduction

In order to sell a vehicle in a specific market, the manufacturer must approve or confirm officially that it meets or exceeds all applicable regulatory standards and specifications. There are three existing methods (Martins, 2010) to officially indicate that a vehicle meets regulatory standards and specifications as presented in table 1.

Table 1
Official methods to indicate that a vehicle meets the regulation

Method name	Certificator / Approval	Examples
Type Approval / Homologation	Government	EU, China, India
Self-Certification	Manufacturer	US and Canada
Combined Self-Certification and Type Approval	combined	Brazil

Source: own

Vehicle Type Approval or Homologation is the confirmation that production samples of a design will satisfy the legal requirements of the market. There are two main methods of type approval in Europe. One is based on the EC Directives and the second is part of United Nations Economic Commission for Europe regulations (UNECE). Both are regulating approval of whole vehicles, vehicle systems and single components. Type approval process contains procedures, events, and timing, which must be followed in order to accomplish homologation in global markets. Because it is approved by a third party and since different markets may have different approval authorities, there could be situations where, even though the regulatory requirements are exactly the same, specific homologation testing and homologation processes are necessary.

In the framework of self-certification process the manufacturer internally should validate that a vehicle meets the applicable regulatory standards of a specific market. Self-certification process contains documentation of requirements, test methods, responsibilities, and evidence required to demonstrate compliance. The vehicle can be registered and sold based on the manufacturer’s self-certification declaration. Government agency has the right to test vehicles to verify compliance to the requirements.

2. Type Approval Process

The vehicle consists huge number of components and systems, each of which must conform to corresponding requirements. Vehicle manufacturers and suppliers of relevant parts to automobile manufacturers must ensure that their products meet those requirements. Type approval makes a distinction between ‘components’ for vehicles - such as lighting components, glazing, rear view mirrors, etc - and ‘systems’ for vehicles, which determine compliance of many components together, such as for braking, steering, crash performance and emissions (VCA). Levels of type approval process are presented in figure 1.

2.1. Component Type Approvals

Component type approvals are designed to approve a component that may be fitted to any vehicle. Manufacturer have to make available about a dozen or more pre-production cars that are equal to final product. These prototypes are used for testing compliance with EU safety regulations, noise and emissions limits as well as production requirements (of individual parts and components, such as seats or steering wheel airbags). If all important requirements are met, the national authority delivers an EU vehicle type approval to the manufacturer authorising the sale of the vehicle type in the EU.

[1] Corresponding author: mate.zoldy@gjt.bme.hu

2.2. System Type Approvals

System type approvals based on component approval are focusing on approval of a set of components or a performance feature of a vehicle that can only be tested and certified in an installed condition (e.g., ie: installation of lights, braking performance or crash tests with dummies)

2.3. Whole Vehicle Type Approval (WVTA)

Once all components and systems have been approved, a manufacturer can request approval of the Whole Vehicle Type. Upon submission of the relevant manufacturer's information document, including reference to the separate type approvals of all systems and components, a European WVTA Certificate will be issued by a type approval authority. The manufacturer shall produce a Certificate of Conformity (CoC) for each vehicle manufactured in conformity with an approved type. A 'type' can best be described as a 'range' of vehicle models that share fundamental characteristics.
The type approval system also allows for a multi-stage approval procedure that applies when the vehicle is built up in more than one step (e.g. by a chassis manufacturer and a body builder). The European WVTA certificate of a vehicle type issued by the approval authority of one member state has to be accepted by all other European member states and allows for the registration of a new vehicle all over the EU.

2.4. Conformity of Production

Conformity of Production (CoP) is a vital part of the approval process. The manufacturer must bring evidence of its capacity to maintain compliance with the approved type for each and every new vehicle manufactured during serial production. This ensures that quality standards are upheld when the vehicle is actually being produced in large numbers. A type approval authority or an authorised technical service conducts the necessary tests and authors a test report. It can use the manufacturer´s test facilities if it is satisfied that the equipment and processes applied meet the necessary quality standards. Finally, the approval authority issues a European WVTA approval certificate. The manufacturer is then responsible for ensuring ongoing Conformity of Production (CoP). By issuing and signing the Certificate of Conformity (CoC) the manufacturer takes full responsibility that all separate regulatory acts are met.

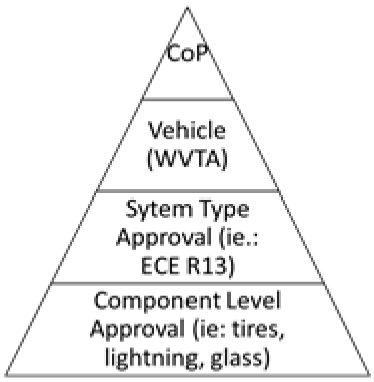

Fig. 1.
Levels of Type Approval

3. Self-Certification Process

First step of self-certification process is definition of complete set of valid prescriptions. In US the Federal Motor Vehicle Safety Standards, or FMVSS, are legal requirements, which are mandated by the government. These define performance and design standards on vehicles to improve safety protection, and they are a sample of self-certification requests.
Items, as motor vehicle equipment and motor vehicles manufactured, to be sold in the United States markets are regulated by US Vehicle Safety Act and they should be certified to comply with all applicable FMVSS. National Highway Traffic Safety Administration's or NHTSA's regulations on motor vehicle certification to be found at 49 CFR Part 567. Principles on the certification of motor vehicle equipment are described as subject to the FMVSS and are published in 49 CFR Part 571, Subpart B.
Main characteristic of US regulations that they are rigorous and robust. There is a robust legal framework and data-driven process which is used by US regulators to develop technical regulations for road vehicles. Main aim of the methods is to validate if the vehicles certified to the relevant technical requirements. There are 65 motor vehicle and motor vehicle equipment safety standards in the U.S., most of them (29) focus on pre-crash (active or crash avoidance) safety, another big branch (27) is about cover crash (passive or crash worthiness) safety and there are some standards about cover post-crash safety (5) and additional 'special' safety standards (4) (Curry, 2016).

Regulations in Canada are described in Canadian Motor Vehicle Safety Standards, or CMVSS, and they are very similar to FMVSS.
Tailpipe and evaporative emissions certifications require government approval in the United States as well. Regulations are set by Environmental Protection Agency (EPA). On the top of the regulatory requirements, vehicles must be also in-line with Voluntary Agreements and guarantee the minimum levels of performance for Public Domain safety ratings (NCAPs).
In Voluntary Agreements Original Equipment Manufacturers secure that the products met a specific requirement and are considered as to be equivalent of government regulations. One of the main aims of New Car Assessment Program (NCAP) is to develop vehicles to "improve occupant safety by developing and implementing meaningful and timely comparative safety information that encourages manufacturers to voluntarily improve the safety of their vehicles" (Hershman, 2001). Corporate Requirements are internal design requirements of producers, which are introduced to either to improve real world safety or to guarantee minimum levels of performance for Public Domain safety ratings.
Finally, production changes should be managed by the OEM with a robust control process, in order to guarantee ongoing regulatory compliance for life of the vehicle. The Compliance Demonstration Data should contain following parts to minimize the risks of some of the most difficult issues to defend in litigation (Martins, 2010):

1. Ensure compliance with FMVSS or Voluntary Agreements;
2. Shows compliance of design changes during a product's life-cycle;
3. Demonstrating a high level of safety; and
4. Proves supportive documentation for design decisions.

4. Comparison of Type Approval and Self Certification

In the comparison of the type Approval and Self Certification the main characteristic can be summarized as the following as in Fig 2.
In case of Type Approval the equipment manufacturer responsibility is to submit product samples for testing, prove compliance through witnessed testing and demonstrate ability to consistently build compliant vehicles, systems, and components. In the same process the role of the governmental approval authority is to review test plans, conduct or witness tests, grants approvals and monitor conformity of production.
In Self Certification process the producers' duty is to ensure compliance with regulatory requirements, document evidence to demonstrate compliance and ensure that products continue to meet regulatory requirements for the lifecycle of the vehicle. Governmental responsibility is to audit production vehicles on purpose and has the right to open an investigation and take the respective legal actions.

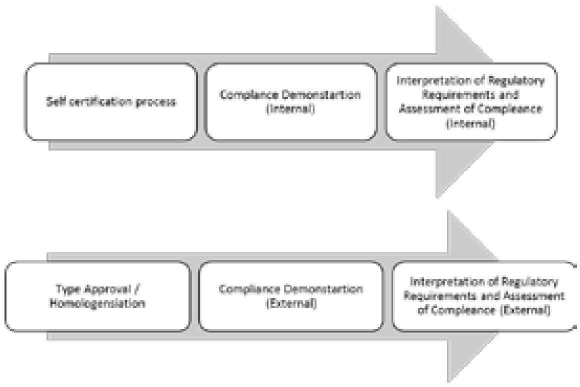

Fig. 2.
Comparison of Homologation and Self Certification

5. Specialities of Autonomous Vehicles

There are still a high number of obstacles for autonomous vehicles, from technical feasibility and legal background to general acceptance by the people. From automotive industry point of view, the main question is how to guarantee safety.
As described previously traditional vehicles have their own validation process either homologation or self-certification. In case of autonomous vehicles, software is an element, which must fulfil high-quality criteria and should be certified itself. Traditional designed test would not be able to measure software elements, and neural networks of autonomous vehicles in an acceptable timeframe (Tettamanti et al., 2016).
It has long been known that it is infeasible to test systems thoroughly enough to ensure ultra-dependable system operation (Pauer and Torok, 2018). As an example, take a theoretical fleet of one million vehicles tested one hour per day, that means 10^6 operational hours per day. If the safety target of this fleet is to have about one catastrophic computing failure in every 1,000 days, then the safety goal is a mean time between catastrophic failures of 10^9 hours, which is comparable to aircraft permissible failure rates (Koopman et al., 2016). The likelihood used in the calculation

means that catastrophic computing failures will happen more times during the life of the fleet of vehicles. To measure and standardise inspections the procedures should be developed and extended.
As first step of inspection process, development automotive vehicles should be classified. There are more classification in use; one of the most used is the SAE classification that is presented in Fig 3. (Hirz et al., 2018).

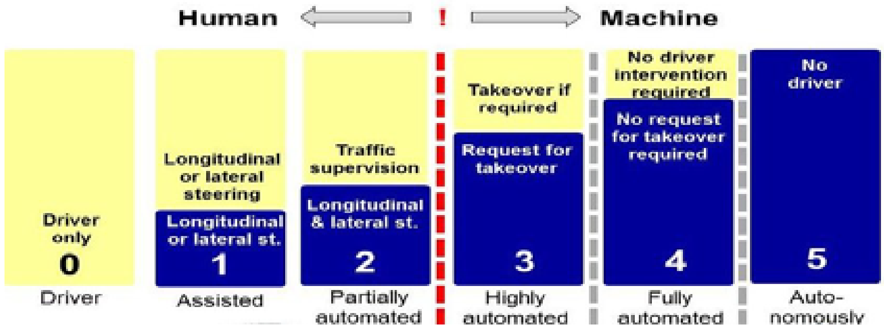

Fig. 3.
Autonomous vehicles SAE classification

Fig 3 shows that with increasing automation more and more complex systems are involved into the environment detection and decision process. Role of artificial intelligence and neural networks are increasing if vehicles are more and more self-driving. It is easy to follow as well, that software role is higher and higher with increasing SAE levels (Godoy et al., 2015; Li et al., 2015). It means that this tendency should be followed as well into the regulation and homologation process. Growing role of software's naturally increase the effect of program refreshments on vehicle behaviour in traffic and based on that the measurement, validation and quality assurance of each software updates. As result of these turn to version verification solutions of informatics should be a next step in development of automotive vehicles and make them suitable for the market.

6. Conclusions

Increased role of artificial intelligence and neural networks should be followed by a focused development in vehicle homologation process to handle specialties and make them compatible with current vehicle validation methods. Increasing role of software and their updates should be covered in the new specifications. In new homologation process development as very appropriate tool (Szalay, 2016) Zalaegerszeg Proving Ground is planned to utilised.

INFLUENCE OF AERODYNAMIC FORCES ON THE STOPPING DISTANCE OF INTERCITY BUSES - invited paper

Ivan Ivković[1]
[1] *University of Belgrade, Faculty of Transport and Traffic Engineering, Vojvode Stepe 305, 11000 Belgrade, Serbia*

Abstract: In this paper an analysis of the impact of drag force and lift force on the bus stopping distance was conducted. The model of the bus in the braking process is shown. Based on the model of the bus, a differential equation of motion was made with a complex solution of stopping distance which takes into account the aerodynamic forces. The stopping distance is analyzed depending on the speed at which the braking starts, changes in the adhesion conditions, the utilization of bus capacity, body shape, air temperature/density. It has been established that aerodynamic forces can influence the decreasing of the stopping distance up to 13% depending on the operating conditions. At lower bus speeds up to 50 km/h, the impact of aerodynamic forces is irrelevant.

Keywords: bus, stopping distance, drag force, drag coefficient, adhesion, braking.

1. Introduction

Aerodynamic forces (drag force and lift force), in addition to rolling resistance, are considered as a constant resistance in vehicle movement process. The intensity of aerodynamic forces depends on a number of factors: speed of vehicle, body shape, density and air temperature (Garrett et al., 2001). Drag force is a consequence of two phenomena that occur when the vehicle moves through the air: turbulence of air around vehicle body and friction of the air particle on the surface of the vehicle body (viscous friction) (Dedović et al., 2017; Gillespie, 1992). Disturbance of air flow is caused by different pressure on the front and rear zone of the vehicle. When the vehicle is moving, the pressure difference occurs due to the compression of the air particles in the front zone of the vehicle and the dilution of the air particles in the rear zone of the vehicle. The component of the drag force due to turbulence is the dominant component in the total drag force with a share of over 80% (Heisler, 2002; Wong 2001). It depends on the shape of the body, i.e. the aerodynamics of the body shape of the vehicle. Friction of the air particle on the surface of the vehicle is a component that depends on how the vehicle surface is smooth but also the size of the contact surface itself. Its share in drag force is about 10-15% (Heisler, 2002; Wong 2001). This component has a significant share when it comes to vehicles of larger lengths, buses, trucks or road trains. The primary impact of drag force on the vehicle is reflected in the reduction in vehicle speed and less on the change in dynamic axle loads. Due to the increase of the air pressure from the bottom of the vehicle and the decrease of the air pressure on the top of vehicle body, the lift force is also has an impact on the movement of the vehicle. The lift force is generally much less intense than drag force, and its impact on vehicle movement is manifested most often through the reduction of axle loads. By applying aerodynamic aids or due to the specific shape of the vehicle body, the lift force can be oriented in the opposite direction, i.e. "down" (Heisler, 2002; Reimpell et al., 2001). In this case, the dynamic axle loads are increased. Changing of the dynamic axle loads affect the adhesion between the wheel and the road surface and therefore on the performance of the vehicle in different operating conditions (drive or braking mode). When braking a vehicle, the action of the executive parts of braking system causes a decrease in vehicle speed. Also, the drag force contributes to decrease the vehicle speed. On the other hand, the lift force can lead to a reduction in axle loads, which negatively affects the length of the stopping distance. i.e. the stopping distance is increasing (Heisler, 2002). Bearing all the above mentioned in mind, the aim of the research in this paper is to quantify and signify the impact of aerodynamic forces on the stopping distance of intercity buses, primarily due to the large frontal area and the low value of the ratio of useful payload and the unladen mass of this category of vehicles.
In this regard, in the first part of the paper, the intercity bus model in the braking mode is defined. According to the model, an equation for a stopping distance is made, which takes into account the impact of aerodynamic forces. In the second part of the paper, the analysis of the stopping distance was performed for a typical example of intercity bus in different operating conditions. At the end of the paper, conclusions and directions for further research were made.

2. The Model

Fig. 1 shows the model of the intercity bus according to which the equations for the stopping distance are made.

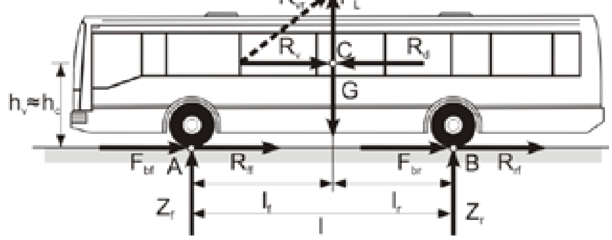

Fig. 1.
Model of Intercity Bus in Braking Process

[1] Corresponding author: i.ivkovic@sf.bg.ac.rs

While braking, the following forces influence on the movement of the bus:

- F_{bf} - braking force on the front wheels
- F_{br} - braking force on the rear wheels

The maximum value of the total braking force, in relation to the available adhesion, is (Eq. (1):

$$F_{bf} + F_{br} = (Z_f + Z_r)\cdot\varphi = (G_A - F_L)\cdot\varphi \tag{1}$$

where:

- Z_f and Z_r - dynamic axle loads on front and rear axle
- G_A - weight of the bus (G_A=G_S+G_K; where: G_S - weight of the empty bus; G_C - total weight of passengers with luggage)
- F_L - lift force ($F_L = \frac{c_L \cdot \rho}{2}\cdot A\cdot V^2$; where: c_L - lift coefficient 0.2-0.3; ρ - air density; A - frontal area of the bus; V - bus speed
- φ - adhesion coefficient

In addition to the total braking force, the following resistance forces influence on the bus movement:

- R_f - total rolling resistance ($R_f = R_{ff} + R_{fr} = (G_A - F_L)\cdot f$; where: f - coefficient of rolling resistance; R_{ff} - rolling resistance on front wheels; R_{fr} - rolling resistance on rear wheels)
- R_d - drag force ($R_v = \frac{c_x \cdot \rho}{2}\cdot A\cdot V^2$; where: c_x - drag coefficient; $A = 0.9\cdot B\cdot H$; A - frontal area of the bus; B - bus width; H - bus height)
- R_i - resistance of inertia ($R_i = \frac{G_A}{g}\cdot a_d\cdot\delta$; where: a_d - deceleration; δ - rotating mass factor; g=9.81m/s^2)

Other labels in the Fig. 1 are:

- C - centre of gravity
- h_c - centre of gravity height
- h_v - point of application of drag force (height of metacentre, $h_v \approx h_c$)
- l_f and l_r - distance of centre of gravity from the front or rear axle
- R_{vr} - resultant aerodynamic force

Based on static equilibrium of forces in the braking process, a differential equation of motion is given by Eq. (2):

$$\sum X = 0 \;\Rightarrow\; R_i = R_{ff} + R_{fr} + R_d + F_{bf} + F_{br} \tag{2}$$

Based on Eq. (2), a general differential equation is obtained in the form, Eq (3):

$$\delta\cdot\frac{G_A - K_L\cdot A\cdot V^2}{g}\cdot\frac{dV}{dt} = \left(G_A - K_L\cdot A\cdot V^2\right)\cdot f + K\cdot A\cdot V^2 + \left(G_A - K_L\cdot A\cdot V^2\right)\cdot\varphi \tag{3}$$

General differential equation based on the stopping distance which includes aerodynamic forces can be given by Eq. (4):

$$dS_{Rd} = \frac{\delta\cdot\left(G_A - K_L\cdot A\cdot V^2\right)}{g}\cdot\frac{VdV}{\left(G_A - K_L\cdot A\cdot V^2\right)\cdot(\varphi + f) + K\cdot A\cdot V^2} \tag{4}$$

The solution of the differential equation represents the stopping distance, taking into account the influence of aerodynamic forces on the movement on the vehicle, Eq. (5):

$$S_{Rd} = \frac{\delta\cdot G_A}{2\cdot g\cdot b}\cdot\ln\frac{a + b\cdot V_1^2}{a + b\cdot V_2^2} - \frac{\delta\cdot K_L\cdot A}{g}\left[\frac{1}{2\cdot b}\left(V_1^2 - V_2^2\right) - \frac{a}{2\cdot b^2}\cdot\ln\frac{a + b\cdot V_1^2}{a + b\cdot V_2^2}\right]\ [m] \tag{5}$$

where:

- $a = G_A\cdot(\varphi + f)$
- $b = K\cdot A - K_L\cdot A\cdot\varphi - K_L\cdot A\cdot f$

- K and K_L - reduced drag and lift coefficients ($K = \frac{c_x \cdot \rho}{2}$, $K_L = \frac{c_L \cdot \rho}{2}$)
- V_2 - speed less than initial speed V_1 (in this research V_2=0 m/s)
- $\rho = 1.225 \cdot \frac{P}{101.325} \cdot \frac{288.16}{273.16 + T}$ $[kg/m^3]$ (Gillespie, 1992), where: P - atmospheric pressure [kPa]; T - air temperature [°C]

If the aerodynamic forces (R_d=0 and F_L=0) are excluded from the analysis, the stopping distance is given by Eq. (6):

$$S = \frac{\delta}{2 \cdot g} \cdot \frac{V_1^2 - V_2^2}{(\varphi + f)} \tag{6}$$

Equations Eq. (5) and Eq. (6) define the stopping distance of the vehicle at the initial speed V_1 with the maximum utilization of the available adhesion on all wheels.

3. Results and Analysis

Analysis of the impact of aerodynamic forces on the stopping distance is performed for the intercity bus with the following basic characteristics: G_S=11400 kg; G_K=3640 kg, B=2.5 m; H=3.24 m (Ivković, 2017; Nijemčević et al., 2001).

The following cases, based on changing of operating conditions are considered:

Case 1. Dependence of the stopping distance on the bus speed for empty bus (G_A=G_S), with a body shape whose drag coefficient is very large (c_x=0.9), poor adhesion conditions (φ=0.15, f=0.010), low air temperature (T=5°C)

Case 2. Dependence of the stopping distance on the bus speed for empty bus (G_A=G_S), with a body shape whose drag coefficient is very small (c_x=0.3), good adhesion conditions (φ=0.95, f=0.020), high air temperature (T=30°C)

Case 3. Dependence of the stopping distance on the bus speed for full-loaded bus (G_A=G_S+G_K), with a body shape whose drag coefficient is very large (c_x=0.9), poor adhesion conditions (φ=0.15, f=0.010), low air temperature (T=5°C)

Case 4. Dependence of the stopping distance on the bus speed for full-loaded bus (G_A=G_S+G_K), with a body shape whose drag coefficient is very small (c_x=0.3), good adhesion conditions (φ=0.95, f=0.020), high air temperature (T=30°C)

Case 5. The influence of the separate operating condition on the stopping distance for a low bus speed (50 km/h) and the constant other typical operating conditions

Case 6. The influence of the separate operating condition on the stopping distance for a middle bus speed (90 km/h) and the constant other typical operating conditions

Case 7. The influence of the separate operating condition on the stopping distance for a maximal bus speed (130 km/h) and the constant other typical operating conditions

Case 8. Furthermost/maximal impact of aerodynamic forces (at low and maximum bus speed, Case 8a, Case 8b, respectively): empty bus (G_A=G_S), with a body shape whose drag coefficient is very large (c_x=0.9); poor adhesion conditions (φ=0.15, f=0.010), low air temperature (T=5°C)

Case 9. Furthermost/minimall impact of aerodynamic forces (at low and maximum bus speed, Case 9a, Case 9b, respectively): empty bus (G_A=G_S), with a body shape whose drag coefficient is very small (c_x=0.3); good adhesion conditions (φ=0.95, f=0.020), high air temperature (T=30°C)

Case 10. Furthermost/maximal impact of aerodynamic forces (at low and maximum bus speed, Case 10a, Case 10b, respectively): full-loaded bus (G_A=G_S+G_K), with a body shape whose drag coefficient is very large (c_x=0.9); poor adhesion conditions (φ=0.15, f=0.010), low air temperature (T=5°C)

Case 11. Furthermost/minimall impact of aerodynamic forces (at low and maximum bus speed, Case 11a, Case 11b, respectively): full-loaded bus (G_A=G_S+G_K), with a body shape whose drag coefficient is very small (c_x=0.3); good adhesion conditions (φ=0.95, f=0.020), high air temperature (T=30°C)

The calculation of the stopping distance was performed in cases of empty and full-loaded buses. In the case of empty bus, when the adhesion conditions are unfavorable (Fig. 2, (φ+f) ≈0,15), the impact of aerodynamic forces on the stopping distance S_{Rd} at speeds of less than 30 km/h is very low (ΔS=S_{Rd}-S<20cm; <0.8%).

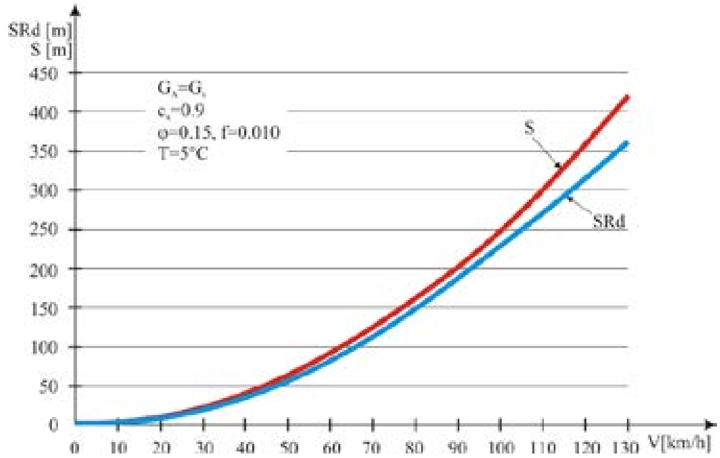

Fig. 2.
Dependence of the Stopping Distance on the Bus Speed for Empty Bus, with a Body Shape whose Drag Coefficient is very large, Poor Adhesion Conditions, Low Air Temperature

With the increase in speed (V=50 km/h), the stopping distance S_{Rd} stopping is 60.1m. This value is 1.34m (2.1%) lower than the stopping distance S. At a speed of 60 km/h, a double difference in the S_{Rd}-S stopping distance can be seen in relation to the speed of 50 km/h. It can be concluded that the speed of 60-65 km is the breaking point after which the stopping distance S_{Rd} significantly differs from the stopping distance S (expressed in meters). At the bus speeds of 75 km/h, 80 km/h, 95 km/h and 110 km/h the difference of stopping distance ΔS takes values: 6.6 m (ΔS%=4.7%), 8.4 m (ΔS%=5.4%), 16.3 m (ΔS%=7.3%), 28.4 m (ΔS%=9.5%) respectively. At the maximum speed of 130 km/h, ΔS takes values of as much as 52.9 m (ΔS%=12.7%). These results are caused by the following operating conditions: low adhesion coefficient φ, high drag coefficient c_x, low air temperature T, smallest possible weight of the bus, i.e. long bus $G_A=G_S$. The mentioned variables take such values that in a common correlation they influence the difference ΔS to be highest.
In the opposite case (Case 2, Fig. 3), in terms of the value of three operating conditions (high adhesion coefficient φ, low drag coefficient c_x, high air temperature T), but for an empty bus, the difference between the stopping distances S_{Rd} and S is insignificant for the entire range from V_{min} to V_{max}. At the maximum bus speed of 130 km/h, the difference ΔS is only 52 cm (0.76%).

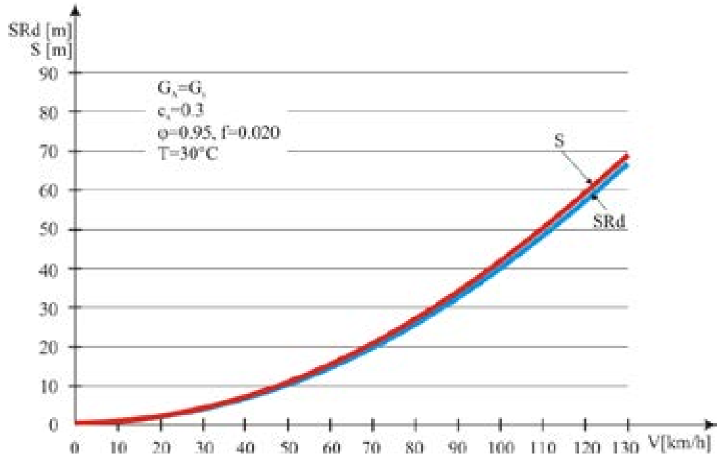

Fig. 3.
Dependence of the Stopping Distance on the Bus Speed for Empty Bus, with a Body Shape whose Drag Coefficient is very small, Good Adhesion Conditions, High Air Temperature

Figs. 4 and 5 show the dependence of the stopping distances S_{Rd} and S on the bus speed for full-loaded bus (the mass of the bus increased by 3640 kg) at the various operating conditions. For favorable operating conditions (from the aspect of achieving the shortest stopping distance S_{Rd}, Fig. 4), the more noticeable difference between the stopping distances, ΔS>3%, is achieved at a speed of 75 km/h.

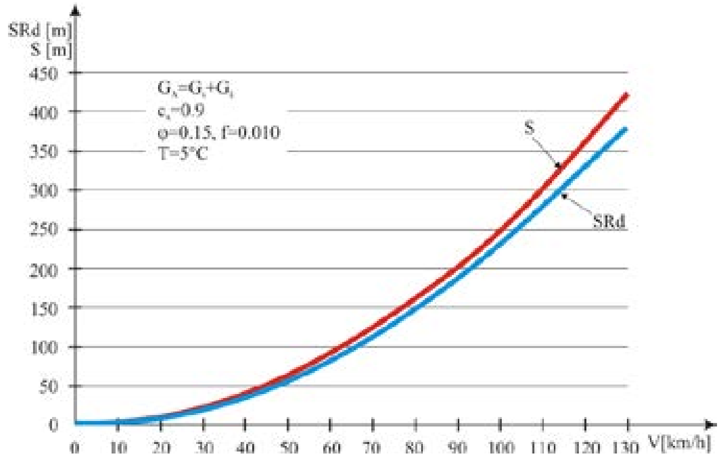

Fig. 4.
Dependence of the Stopping Distance on the Bus Speed for Full-Loaded Bus, with a Body Shape whose Drag Coefficient is very large, Poor Adhesion Conditions, Low Air Temperature

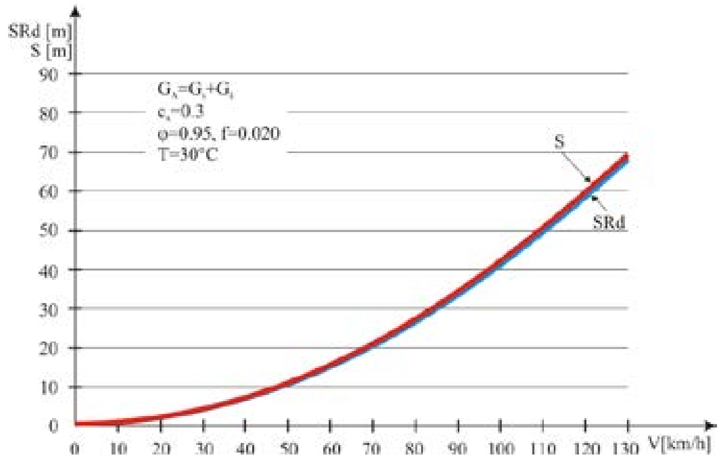

Fig. 5.
Dependence of the Stopping Distance on the Bus Speed for Full-Loaded Bus, with a Body Shape whose Drag Coefficient is very small, Good Adhesion Conditions, High Air Temperature

The change of ΔS increases with a change in bus speed with a lower intensity than shown in Figure 1. At the maximum bus speed, ΔS is 2.7% less than in the Case 1 shown in Fig. 2. For unfavorable operating conditions, the curves S_{Rd}=f(v) and S=f(v) are almost completely overlapping. The maximum value for ΔS (at a speed of 130 km / h) is less than 0.184% (12.5 cm) than in the Case 2 shown in Fig. 3. These results indicate that the change in capacity utilization of intercity buses does not significantly affect the SRd stopping distance.
The Figs. 6, 7 and 8 show the separate effect of operating conditions on the value of the S_{Rd} stopping distance. In the first step, typical values for all four parameters were adopted (Table 1).

Table 1
Typical Values of Operating Conditions

adhesion coefficient φ [-]	**drag coefficient c_x [-]**	**utilisation of bus capacity n [no. of passengers [kg, N]**	**Air temperature T [ºC]**
0.85	0.4	32 passengers (≈17854 N)	20

In the second step, one parameter was varied from minimal to maximum, while other parameters retained typical values. The analysis was carried out in three cases of speed: low speed - 50 km/h (Fig. 6), midle speed - 90 km/h (Fig. 7) and maximum bus speed - 130 km/h (Fig. 8).
In all three cases, the coefficient of adhesion has a dominant influence on the S_{Rd} stopping distance. At a bus speed of 50 km/h (Fig. 6) and a minimum adhesion coefficient (φ=0.15), with a typical value of other operating conditions, the stopping distance is about 58 m. The lower changes in the stopping distance occur when the coefficient of adhesion increases from the value φ=0.34 to the maximum value φ=1.0. This change in this range is about 18m. When changing the coefficient of adhesion from minimum to maximum, the change in the stopping distance is about 48 m. For the lowest value of the coefficient of adhesion, the difference of the stopping distances S and S_{Rd} is very small and it is ΔS=0.45 m. As noted in Fig. 5, the changes in other operating conditions (draf coefficient, utilization of bus capacity

and air temperature) are completely negligible from the standpoint of the influence on the value of the stopping distance at a bus speed of 50 km/h.

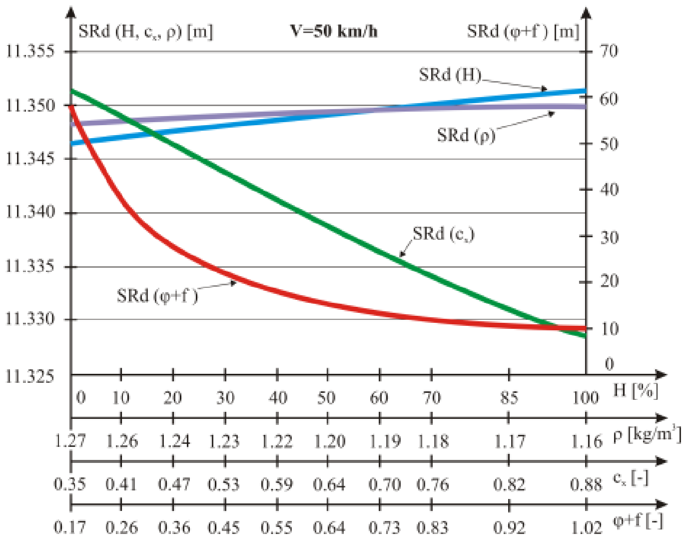

Fig. 6.
Influence of the Separate Operating Condition on the Stopping Distance for a Low Bus Speed (50 km/h) and the Constant Other Typical Operating Conditions

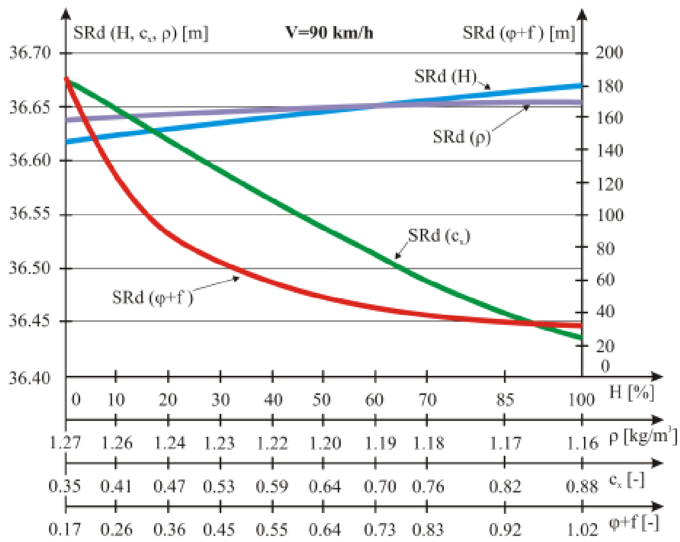

Fig. 7.
Influence of the Separate Operating Condition on the Stopping Distance for a Midlle Bus Speed (90 km/h) and the Constant Other Typical Operating Conditions

At a speed of 90 km/h (Fig. 7), the change in the coefficient of adhesion from minimum to maximum causes a change in the stopping distance S_{Rd} of 154 m. At the lowest adhesion coefficient, the difference in the stopping distances S_{Rd} and S is around ΔS=4.6m, which is about 10 times higher than in the case of a bus speed of 50 km/h. The maximum value of the drag coefficient (c_x=0.88) causes the difference between the stopping distances S_{Rv} and S about 0.4m (1%). The other two parameters, the utilization of bus capacity and the air temperature have an insignificant individually effect on ΔS (below 1%).
Fig. 8 (bus speed=130 km/h) show that the changing of the coefficient of adhesion from minimum to maximum causes a difference in the stopping distance S_{Rd} of 310m. If it is excluded from the analysis the drag force, the change in the stopping distance ΔS, at the minimum adhesion coefficient (φ=0.15) is 19.5 m (decrease by 5%). Changing of the air drag coefficient from minimum to maximum value causes the difference in the S_{Rd} distance by 1m. For c_x=0.4, the difference between the stopping distance ΔS is about 1.7m (decrease by 2.2%). The air temperature and the utilization of bus capacity slightly higher affect the values of S_{Rd} and ΔS than a speed of 90 km/h, but the changes are around 1%.

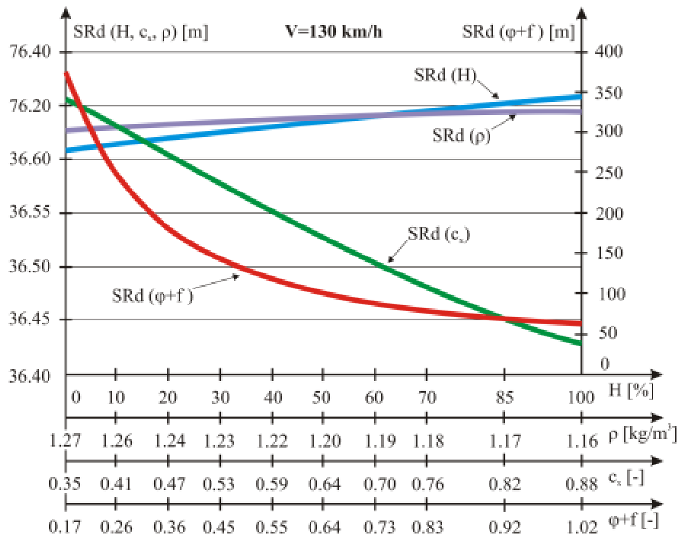

Fig. 8.
Influence of the Separate Operating Condition on the Stopping Distance for a Maximum Bus Speed (130 km/h) and the Constant Other Typical Operating Conditions

Table 2 and Fig. 9 show the furthermost minimal/maximal effects of aerodynamic forces on stopping distance of intercity bus. The data is given for the full-loaded and empty vehicle and for the low and maximum bus speed. When the bus is empty, the maximum shortening of the sstopping distance S_{Rd} is about 13%, in the case of primary unfavorable conditions of adhesion when the braking starts at a speed of 130 km/h.

Table 2
Minimal/Maximal Effects of Aerodynamic Forces on Stopping Distance of Intercity Bus

Case	Minimal/maximal effects	S_{Rd} [m]	S [m]	ΔS [m]	ΔS [%]
8a	max. impact, empty bus, V=50 km/h	60.109	61.449	1.340	2.181
8b	max. impact, empty bus, V=130 km/h	362.485	415.396	52.911	12.737
9a	min. impact, empty bus, V=50 km/h	10.124	10.136	0.011	0.113
9b	min. impact, empty bus, V=130 km/h	67.997	68.519	0.522	0.763
10a	max. impact, full-loaded bus, V=50 km/h	60.426	61.449	1.023	1.665
10b	max. impact, full-loaded bus, V=130 km/h	373.697	415.396	41.700	10.039
11a	min. impact, full-loaded bus, V=50 km/h	10.127	10.136	0.009	0.086
11b	min. impact, full-loaded bus, V=130 km/h	68.123	68.519	0.396	0.578

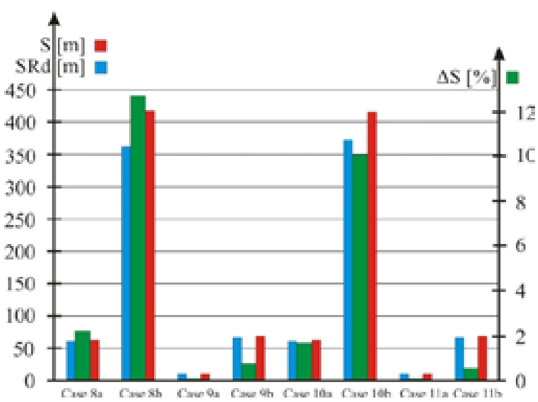

Fig. 9.
Minimal/Maximal Effects of Aerodynamic Forces on Stopping Distance of Intercity Bus

For the predominantly high adhesion coefficient and low speed of the change in the stopping distance is ΔS≈0.1%, ie. the influence of the aerodynamic forces is almost completely negligible. In case of full utilization of bus capacity, the ΔS values differ by a maximum of 2% at a speed of 130 km/h.

Conclusions

Based on the previous one, the following conclusions can be made:

- The most influential factor from the standpoint of impact of aerodynamic forces on the stopping distance is adhesion coefficient
- Under low adhesion conditions when the bus is empty, significant differences in the stopping distance occur at speeds higher than 60 km/h, the value of $\Delta S > 3\%$. With full utilization of bus capacity, identical differences occur at a speed of about 75 km/h. If the adhesion coefficient is high, in both cases (full and empty bus) the value of ΔS is very small ($\Delta S_{max} < 0.8\%$) for the entire range of speeds from 50 to 130 km/h, irrespective of the value of other variable operating conditions.
- By analyzing the bus while braking, in typical operating conditions, it can be concluded that after the adhesion coefficient, the most influential factor on the stopping distance S_{Rv} is the drag coefficient c_x. At high speeds, the highest value of drag coefficient causes a maximum change in the stopping distance of about 2%. The utilization of bus capacitiy and air temperature are two factors that quantitatively very similarly influence the change of the stopping distance, but these effects are very small (maximum value $\Delta S \approx 1\%$).
- In the furthermost/minimal case, the common influence of the most unfavorable values of the parameters from the standpoint of achieving of minimum value ΔS ($\varphi=\varphi_{min}$, $H=H_{max}$, $c_x=c_{xmin}$ and $T=T_{max}$, $V=50$ km/h) is reflected by decreasing of the stopping distance due to the impact of aerodynamic forces, in the amount of only 0.1%.
- In the opposite furthermost/maximal case case ($\varphi=\varphi_{max}$, $H=H_{min}$, $c_x=c_{xmax}$ and $T=T_{min}$, $V=130$ km/h), the common influence of the most favorable values of the parameters from the achievement of the maximum value of ΔS is reflected by the decreasing of the stopping distance due to the impact of aerodynamic force, in the amount of about 13% ($\Delta S \approx 53$m).
- The results in this research indicate that in the analysis of the stopping distance of intercity buses, in conditions of high adhesion and low speeds, the impact of aerodynamic forces can be irrelevant. Otherwise, at speeds higher than 60 km/h with low adhesion values, it is necessary to take into account the common influence of all four factors due to the evident differences between the stopping distances S_{Rv} and S.

REMARKS: The analyzes and conclusions presented in this paper take into account the specificity of intercity bus as a motor vehicle in relation to other categories of vehicles, which are primarily: a large frontal area and a relatively low value of the ratio of useful payload and the unladen mass. The impact of aerodynamic forces on the stopping distance may be more significant than the above if, during braking, the influence of the wind is calculated in the opposite direction from the direction of movement of the bus, which will be the goal of the next subsequent research in the future. Since the objective in this study relates strictly to the vehicle, the results do not include the impact of the driver's reaction time on the stopping distance in braking process, i.e. the stopping distance is elaborated from the moment of the occurrence of deceleration.

DRAFT OF HANDLING EQUIPMENT FOR MATERIAL ELEMENTS TRANSPORTATION

Ján Ližbetin[1], **Vladimír Ľupták**[2]
[1,2] Institute of Technology and Business in České Budějovice, Faculty of Technology, Department of Transport and Logistics, Okružní 517/10, 370 01 České Budějovice, Czech Republic

Abstract: The article deals with material handling in transport sector. The output is the proposal of handling equipment facilitating and streamlining handling and transportation of physical elements (loader cranes and container carriers, or their components). Using the proposed handling equipment enables to streamline the corporate logistic processes and solving problems currently arising in the company, especially in loading operations. Handling will be carried out directly in the manufacturing company and at the customer (transportation of spare parts within the after-sales service).The first part of the article focuses on characterizing the individual logistic problems arising during the manipulation with the material in the company. The first logistic problem is the manipulation with the components on the premises of the company (when unloading from the vehicles, when transporting the individual parts during the assembly of the equipment). The second logistic problem is the transportation of the components and spare parts directly to the customer within after-sales service. The third logistic problem consists in unloading the components transported from suppliers. The second part of the article deals with the proposal of a handling device consisting of the proposal of a suitable trailer, calculation of the stability of the handling device, proposal of individual components of the handling device and proposal of hydraulic lifting device including the hydraulic unit.

Keywords: transportation, freight transport, handling equipment, material handling.

1. Introduction

Manipulation in its basic division can be divided as manual, combined and mechanized handling. Manual handling consists in physical transportation of a physical object over a defined handling track by lifting, pushing, pulling, moving, rolling and putting down.
Handling device is defined as a tool or element which enables performing of handling operations using manual or mechanized handling by means of handling device. Handling device is not a detachable part of handling equipment. It is e.g. a tool for gripping the object, supporting the object, tool with a specific connection to the handling operation etc. Handling devices include also handling aids (Celjak, 2013), (Michalski, 2016).
The presented article is an output of a research project focused on prosing handling device for a concrete company engaged in selling hydraulic power devices of a wide power spectrum. Additionally, the company is engaged in selling accessories for loader cranes, manufacturing dropside trucks bodies and mounting of hook carriers which serve as a transport unit of large-volume containers (Cortes et al., 2017), (Koh et al., 2017). The internal structure of the company´s value-creating logistic chain conceals a number of logistic problems that are mentioned in the following part of this article.

2. Characteristics of Individual Logistic Problems

Handling with assembly components or spare parts conceals a number of logistic problems that have to be optimized in order to avoid unnecessary handling operations.

2.1. Logistic Problem 1.

Upon arrival of the articulated vehicle with a semi-trailer that primarily serves for the transport between the manufacturing company in Lengau and headquarters in České Budějovice, the company does not have any handling device that would be used for unloading the products from the load-carrying platform and store it in the pre-defined space. By this time, these operations were performed using a forklift truck. Its manipulation is not restrictive. The main problem is that the company has only one handling device of this type, which means this is often used for other handling operations and is not at disposal. Another disadvantage is its kinematics which does not allow placing the object behind an obstacle or over a slight horizon. This problem arises in the company hall, where the stored items are often moved or relocated. If the item or component were situated behind the parts that were not needed at that time, it was necessary to relocate those parts so that a handling space was created and the given products or components could be transported.
Since the designed device is transportable, it is possible to place it at any defined location so that the maximum radius of action is ensured. The designed handling device, however, will not be able to handle hydraulic jib cranes weighing 20 tonne-meters (hereinafter referred to as TM) and more. This is due to the fact that the stability of the whole system would not be ensured and the requirement of a total weight not exceeding 3,500 kg would not be met.

[1] Corresponding author: lizbetin@mail.vstecb.cz

Thus, the handling device will be placed so that it is able to unload the products from the load-carrying platform of the semi-trailer of the lorry and store them in a defined place. Furthermore, it will be possible to get this kinematic unit with the object being relocated through the already stored objects intended for the assembly process.

2.2. Logistic Problem 2.

The company also faces a problem of getting spare parts for the customer within the warranty period. The warranty period is usually between 1 – 3 years, depending on the type of the spare parts. The three-year warranty period is usually for so-called load-bearing components. One-year warranty period usually covers hydraulic and electrical spare parts. Since the market is very competitive, the company has decided to offer the customer the free transport of the spare part to the pre-selected place within the Czech Republic (within the warranty period). Of course, this service is offered only in case the guarantee is recognized as valid by the guarantee technicians.

By this time, this service has been provided by hired transport companies that have the necessary vehicles at disposal. However, there were often problems with unavailability of the trucks or that the service required trucks of higher weight, and therefore the rent was very expensive.

Since the proposed handling device was detachable from the trailer, the company management decided to use the trailer for the above mentioned purpose. Moreover, the advantage of the whole set would be the ability to load the contested object. A small disadvantage would be the fact that this handling device would not be available at the unloading point. This handling operation would thus have to be ensured by the customer.

2.3. Logistic Problem 3.

Since the company is not engaged only in selling hydraulic equipment, but also in manufacturing sub-frames and dropside trucks, it is necessary to ensure the transfer of materials necessary for their production. These are mainly various types of profiles and sheets, bars and chipboard parts. Handling with these materials has been ensured using a company van, which unfortunately did not have enough space for loading. Another constraint was unloading, when a forklift truck had to be used, which is frequently used and thus often unavailable.

The proposed handling device could be used also for the aforementioned operations. In such a case, the hydraulic device would be placed at a suitable place so that it could handle the unloading of the material from the load-carrying platform of the trailer and relocate the material to a place intended for raw material entering the assembly.

3. Design of Handling Device

The company determined the basic technical requirements and parameters for the device, which could be described as follows:

- category O2 (trailer of the maximum permissible weight exceeding 750 kg but not higher than 3,500 kg) (Curry and Deng, 2017),
- vertical loading on the hinge pin not higher that 100 kg (data from the trailer technical sheet),
- hydraulic range at least 9,000 mm,
- capability of manipulation with object of 500 kg weight at a range of 9,000 mm,
- capability of manipulation with object of 700 kg weight at a range of 7,000 mm,
- capability of manipulation with object of 900 kg weight at a range of 5,000 mm,
- required approval of legislation on road traffic,
- ensured stability of the whole set at given loading capacity (without the tow vehicle),
- the total height must not exceed 3,200 mm,
- securing of electrohydraulic unit to 25A (Yamazaki et al., 2017), (Gomez-Montoya et al., 2016),
- Capability of manipulation with the object in the 360° range.

3.1. Design of Category O2 Trailer

Starting condition for choosing the chassis was mainly the total weight not exceeding 3,500 kg. The trailer must have its own braking system, must be a two-axle one, must have the lowest load-carrying platform possible and must be legally included into the 02 category.

The company was offered a trailer from the company VEZEKO s.r.o. No concrete type was chosen. The reason is the specific anchorage of the hydraulic arm in the trailer. The coupling of the individual components (hydraulic device and trailer) will be ensured by means of joints, so that the disassembly and reassembly are as easy and fast as possible. The starting type is CARGO D35.2 with a load-carrying platform of 2600 x 1620 mm and the total weight not exceeding 3,500 kg. The frame consists of robust, hot dip galvanized frame with three transverse reinforcements. The trailer has a very modern design, with high strength and resistance to stress. The platform is fitted with the KNOTT or AL-KO axles. The floor is made of waterproof plywood with 6 pairs of anchoring meshes for cargo retention on the load-carrying platform in the situation when the handling unit is not used. The chassis is supplied with detachable aluminum side panels. However, these are unnecessary in our case; therefore the trailer was ordered only as a platform, that is, without aluminum sides (Mhalla et al., 2016).

Fig. 1.
Trailer of Category O2
Source: www.vezeko.cz

3.2. Calculation of Handling Device Stability

One of the most important parts of the design is the calculation of adequate stability when working with hydraulic power device. The stability will be ensured by four support points with dimensions of 6000 x 6000 using telescopic slides. This type has been chosen because of the total transport height of the device. If there were fixed supports, the height in the transport position would exceed the required condition of maximum 3200 mm. Furthermore, it is necessary that the vertical load on the hinge pin does not exceed 100 kg, which is the maximum value for tow trailers of N1 category, from the extract of the registration documents. Another condition is the fact that the overall weight of the set including the two-axle trailer must not exceed 3500 kg, which is the maximum allowed weight for the O2 category. For the calculation of stability, company program PACWIN was used. Firstly, the weight and dimensions of the chassis are fed into the program. In this case, it refers to the dimensions and the unladen mass of the trailer. Next, all the relevant weights will be entered. After completing all the necessary parameters, the program calculates the resulting stability / instability (lability).
The mass of the testing load for the stability test (Sulirova et al., 2017), (Esfandeh et al., 2016):

$$TL = K_s * P + 0.1 * G_p$$
$$K_s = 1.15 + \frac{\mu}{100}$$

where:
TL – mass of testing load,
Ks – stability factor,
P – loading capacity,
Gp – weight of the job system related to the load suspension point point,
μ - load limiter tolerance.

G_p and μ values must be documented by the manufacturer (ČSN EN 12999, 2003).
The EN 12999 standard deals with the minimum stability factor, where the whole SET can be considered safe and stable. The value of the stability factor is 1.4, or the sum of the stability moments must be at least by 40 % higher than the sum of the heeling moments (Fedorko et al., 2018), (Cokorilo, 2016).
For the stability calculation, the following peripherals will be considered:
- The mass of the hydraulic device distributed between the static and dynamic parts,
- The mass of the supporting cross mechanism,
- The mass of the drive unit,
- The mass of the tank,
- The mass of the pressure medium (oil),
- The mass of the hydraulic systems and additional hydraulic components.

The calculation considers additional load for increasing the total weight and thus for improving the stability. For detailed calculation, see (Setka, 2017).

Table 3

Mass distribution and relevance

	Heeling moment			
	A	B	C	D
Moment of stability (mt) - MS	9.16	11.01	9.51	8.62
Heeling moment (mt) - MT	4.32	3.72	3.77	4.13
Position of tow vehicle center of gravity to tilting axis D-TR	3000	3536	3000	2764
Distance between load and tilting axis D-LC	6525		5825	6293
Weight of hydraulic device parts within the tilting axis W-CI	648	683	683	648
Position of center of gravity of static parts of hydraulic lifting device D-CWI within the tilting axis	2333	2931	2735	2430
Weight of the hydraulic device dynamic parts outside the tilting axis W-CO	253	218	218	253
Position of center of gravity of the hydraulic lifting device D – CWO dynamic parts outside the tilting axis	2875	2521	2589	2643
Resulting stability factor	2.12	2.96	2.52	2.08

Source: computing program PACWIN – NET; Palfinger software

From the resulting values, especially the resulting stability factors it follows that such designed set with a total weight of 3481 kg is stable in all quadrants. The highest value of the stability factor (2.96) is in the B quadrant, the lowest value (2.08) is in the D quadrant. The sun of the stability moments is by 208 % higher than the sum of the heeling moments. During the implementation it will thus be necessary to load the whole set by necessary "ballast" so that the whole set has the required stability according to the EN 12999.

3.3. Hydraulic Lifting Device PK_6501_HP

Hydraulic lifting crane PK 6501 HP was chosen as a lifting device for the handling device. HP stands for "High Performance". It is a lower power lifting device. The first two digits refer to the lifting capacity in tonne-meters, which is in this case 6.5 TM. This value is purely theoretical and it is based only on the calculation, not on the testing in practice. The main reason is the kinematics of the device. 01 means that the hydraulic device has one lever mechanism. In this case it refers to the lever mechanism between the main and tilt jib (Kampf et al., 2017). The main parts of the hydraulic device include the pedestal, support legs or support mechanism, tower, main jib, tilt or second jib with telescopic arm system.

Fig. 3.
Hydraulic lifting device PK_6501_HP
Source: authors

3.4. Hydraulic Unit

The hydraulic unit will serve as a source of pressure and volume flow of hydraulic oil in the system. It will consist of an electric motor that will be powered by the voltage of 380V. The electric motor will have forced cooling (blades) mounted on its rotor, which will cool the heating coil during the operation. This is a very important aspect since the motor will work even when the hydraulic device is not working but the system will still be active (the oil will circulate in the hydraulic circuit). The hydraulic aggregate will be equipped with a STOP button, whose activation will interrupt the power supply and the engine rotor will stop spinning and therefore the system will not be supplied with the oil pressure. This is absolutely necessary in terms of security. On the shaft of the electric motor, eccentric gear pump will be attached, which will consist of one gearwheel with external gearing and one gearwheel with internal gearing (Krol et al., 2017), (Moczko et al., 2018).

4. Results

4.1. Design Assessment From Logistics Point of View

The first logistic problem becomes to a certain extent an overall ailment of the whole object. Furthermore, there are no "conventional" handling devices for unloading from trucks to storehouses. Since the hydraulic radius of the proposed handling device is 5200 mm, it can be positioned so that it serves the load-bearing platform without problems and place the object to a given site in the store. The site can be at the distance not larger than 5200 mm from the pivotal axis, if its nominal weight is not higher than 1120 kg (11.0 KN). If the weight of the suspended object is closer to 1680 kg (16.5 KN), the radius of action will be reduced from 2 x 5200 mm to 2 x 3500 mm.
The main advantage of the proposed hydraulic lifting device will be the capability to store and handle the objects which are not closest to the distribution point (thus eliminating the ineffective handling operations for additional relocation of the stored items in the storehouse). Using this handling device, it will be possible to place the items to pre-determined, fully used space (Blaho et al., 2017).
Since the company has only one forklift truck at disposal, this will also reduce the downtimes when the forklift truck had to be used in the storehouse and was not available at other places in the company.
Furthermore, after dismantling the trailer, it will be possible to take an item from the store and transport it either to service or assembly workshop. A disadvantage is the fat, that it will be necessary to use also a trailer, since the truck is not self-propelled (Varun et al., 2017), (Kamaryt and Kleinova, 2016).
The second logistic problem has been completely solved by using the handling device. The weight of the trailer itself is 550 kg, so the load capacity is 2950 kg. This could be handled by hydraulic arm without any problems. It is only necessary to ensure that the given object is placed in the horizontal direction so that the suspension device is not overloaded. The trailer will be equipped with mechanical fittings, which will serve as fixing points for bindings and

securing transport elements. The objects of higher weight can be also relocated using the handling device, but cannot be loaded onto the trailer, because this way one of the axles would be overloaded and the vehicle would not be suitable road traffic.
The third logistic problem arises when purchasing and transporting the material to the assembly workplace. This workplace has so-called temporary intermediate storehouse, where the semi-finished products are stored until they are used for further technological operations in a short time horizon. For these operations, the trailer will be used, which will transport the material, and using the handling device, it will store it in the intermediate storehouse (Ivkovic et al., 2018).

4.2. Assessment of Proposal From Economic Point of View

The first logistic problem can be assessed in terms of time savings. The estimated time savings could be around 25 % per hour. This value is not that significant; however, it should be taken into account that the transport of spare parts is an every-day issue. Thus, any time and hence financial savings will be noticeable.
The second logistic problem can be expressed exactly. The rent of the N2 category trailer, the most frequently used trailer even for transporting less bulky objects, is CZK 25 / km. The usability of payload is very low, therefore the rent if often not economical, yet necessary due to the need to comply with the conditions of sale. The cost of operating the trailer can be estimated at CZK 8 / km. However, the cost of operating the tow vehicle, which is approximately CZK 9 / km, must be included. After aggregating these two items, the savings is about 32 % per one km. In addition, the lengthy process of ordering the carrier by the sales department or looking for another carrier is reduced if the carrier´s vehicles are fully utilized (Shepelev et al., 2016).
The third logistic problem consists in transporting the material from the purchasing point to the manufacturing hall of the company. The advantage of using a trailer is the possibility to transport bulky items which could not be transported in loading space of the van ensuring these operations. Furthermore, using this set (van + trailer) it is possible to transport larger quantity of material per the same time unit. The financial savings thus consists in time savings. The exact numbers will be known after testing in practice (Kostrzewski, 2012).

Conclusion

In the introduction, three logistic problems were defined that were supposed to be solved by using the given handling device. The statements and individual assessments are only theoretical, since the handling device was not finished at the time of writing this article and was still under development.
However, based on the development it can be said that using the handling device can solve the first logistic problem from the technical point of view; it only cannot be stated to which extent the solution will be favorable in terms of finance and logistics.
The proposed device is also capable of solving the second logistic problem; however, there is a matter of storing material at the place of the customer´s request. This problem can be solved by a different construction and weight solution, which, however, would be at the expense of the performance of the hydraulic device (the hydraulic arm would reach the lower lifting moment so that it does not exceed the weight limit) and there would be a problem with the overall stability, or lability of the set. The components of the imported device must be agreed with the customer over the phone and it is necessary that the customer carries out the unloading at their own expense, which, however, does not have a significant financial impact on the process of the spare parts transport.
It is assumed that the handling unit will be able to fully solve the third logistic problem. However, the economic point of view can only be evaluated after longer period of time when the crane is assembled and is operational.
The authors see a certain disadvantage of the construction in the form of fitting the load-bearing construction to the hydraulic device and trailer. Since the principle of handling consists in supporting the weight of the system by support legs so that the trailer would be able to move, the authors see a possible in pin connection, which could get stuck and due to the influence of the mechanical and dynamic strain fails to perform its function. Therefore, it will not be possible to detach easily the self-supporting body from the trailer.

COST MANAGEMENT IN LOGISTICS OF WAREHOUSING: THE USE OF ACTIVITY-BASED COSTING IN THE LOGISTICS SERVICE PROVIDER

Tomáš Kučera[1]

[1] *University of Pardubice, Faculty of Transport Engineering, Department of Transport Technology and Control, Czech Republic*

Abstract: The activity-based costing method is considered as a universal management tool that applies to flow mapping and cost behavior. The basic idea of activity-based costing is to find the true causal link between cost and performance and to display these facts in the calculation system so that the outputs are as close as possible to the reality. This method defines the structure of business processes and activities. Activity-based costing primarily focuses on improving the assignment of overhead costs, which are often allocated on a direct cost basis or direct worked hours. This method was imported to address the problems encountered by logistics service providers. The aim of this article is to use activity-based costing as a management method in a logistics service provider with regard to the cost management. The article is based on research of the world literature especially Web of Science database and Scopus database, in-depth interviews with managers that is the method of the qualitative research and an analysis of internal data of the logistics service provider. The basic advantages of qualitative research are the detailed description and insight into the study of the issue, in addition it responds well to local situations and conditions and can search for local causal connections. The article shows the possibility of using activity-based costing to better calculate the logistics costs of warehousing in a selected logistics service provider.

Keywords: activity-based costing, logistics costs, logistics service provider, cost calculation, warehousing.

1. Introduction

The logistics services which are provided must be a source of value not only for the final customer but for all interested stakeholders. A prerequisite for evaluating the effectiveness of all activities is cost monitoring across the entire supply system, including logistics service providers.

Definition of company processes whose costs will be included in total logistics costs, including their allocation to cost objects (orders, services, departments, processes, etc.). It is a basic step in monitoring and evaluating logistics costs to support decision-making tasks (Kučera, Hyršlová and Sommerauerová, 2017).

As stated by Richards and Grinsted (2013 and 2016) warehousing, as an integral part of the logistics system, dynamic and interactive activity is geared to the level needed to meet demand. When delivering logistics services, it is important to make efficient use of both time and warehouse or local space. According to Accorsi, Manzini and Bortolini (2012) and Accorsi, Manzini and Maranesi (2014), emphasis should be placed on planning all warehouse activities, including receipt, warehousing, assembly, kitting, picking and ordering from customers. Warehouses make it possible to unify, distribute bulk goods, transfer and collate cross-docks and provide value-added services.

The concept of logistics costs is defined by many authors. According to Straka and Malindžák (2005), logistics costs are expressed as the sum of all costs associated with the implementation of logistics processes. These costs are associated with the realization of material flows, mostly costs related to transportation, warehousing, financial reinsurance, insurance and information flows. According to Bazaly et al. (2006), logistics costs can be understood as the sum of all the costs associated with organizing, controlling and implementing the logistics process itself, within all the articles in the supply chain. Pražská and Jindra (2002) divide logistics costs into the same groups as Schulte (1994); these authors agree on the definition of logistics costs: supply costs, warehousing costs, transport costs and handling costs. Kučera (2017) argues that logistics managers are usually interested in providing high quality services to their customers at minimum cost.

2. Literature Review and Methodology

Activity-based costing provides a new approach to tracking and assigning costs. Unlike traditional calculation methods, it does not use the cost allocation of a costing unit (such as a product) through cost centres, but through activities that are necessary for the creation of performance. The reasons for this shift in cost allocation can be found in changes (high diversification of product portfolios, service differentiation, short product life cycles, growing customer demands for product diversity and quality, growth of suppliers and customers) that accompany business activity (Bokor and Markovits-Somogyi, 2015; Hansen and Mowen, 2007). Traditional calculations cease to provide relevant driving information in these unstable conditions. They provide an answer to the question as to what costs have been incurred and how they have been allocated to in-house centres, or how each product or product group is involved in the costs, but does not answer the question as to why these costs have arisen (Wang, 2017). The activity-based costing calculation returns to the cause-effect relationship. It abandons the traditional assumption that the causal cost is mainly volume (for example: time consumption, material value) (Gros and Grosová, 2012; Stevenson and Cabell, 2002).

The basic purpose of the activity-based costing calculation is therefore to accurately express the relationship of costs to the cause of their occurrence, especially when the increase in costs is not due to an increase in the volume of the final

[1] Corresponding author: tomas.kucera@upce.cz

outputs. From a methodological point of view, it is basically a full cost calculation (absorption method) that can be combined with a non-absorbent method (Mocanu, 2008). Narsaiah and Chary (2017) claim that activity-based costing has become a tool in the hands of logistics service provider to surmount the problems with regard to cost management.
In terms of origin, the activity-based costing is linked to the 1980s with the names of Kaplan, Cooper and Johnson. At this time in the USA, the first articles are published (dealing with the originators of the emergence of overheads and the deficiencies of traditional costing procedures in the scheduling of these overheads). At the same time, the first concepts of the activity-based costing method were presented as methods for assigning overhead costs as well as for measuring and evaluating costs and process performance (Cooper and Kaplan, 1987; Cooper and Kaplan, 1992; Kaplan and Cooper,1998).
Bokor and Markovits-Somogyi (2015) present that, given the general characteristics and the current adaptation of the activity-based costing method, the costs of certain logistics services consist of four parts (see Figure 1):

- direct costs derived from the accounting system,
- variable indirect costs from primary activities, the allocation is based on performance,
- fixed indirect costs arising from primary activities, the allocation is based on time consuming,
- indirect costs from secondary activities, the allocation is time-based.

Time consuming is the total duration of logistics services (transport, warehousing and sometimes other activities).

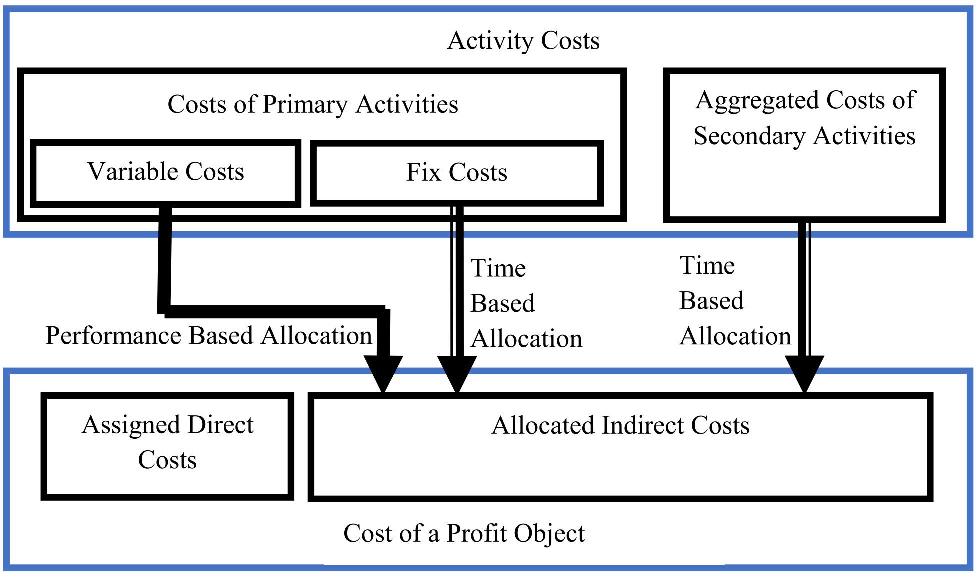

Fig. 1.
Activity-Based Costing Model
Source: Bokor and Markovits-Somogyi (2015)

Primary activities are indexed as i = 1 ... n, while profit objects, i.e. logistics services, are indexed as j = 1 ... m. The formula (1), which consists of four components, is used to calculate costs.

$$C_j = C_j^d + \sum_{i=1}^{n} C_{v_i} \frac{P_{ji}}{P_i} + \frac{T_j}{\sum_{j=1}^{m} T_j} \sum_{i=1}^{n} C_{f_i} + \frac{T_j}{\sum_{j=1}^{m} T_j} C^{sa} \text{ [CZK]} \quad (1)$$

Where:

C_j Cost of profit object j [CZK]
C_j^d Direct cost of profit object j [CZK]
C_{v_i} Variable cost of primary activity i [CZK]
P_i Performance of primary activity i [differently expressed power units]
P_{ji} Performance consumption of profit object j at primary activity i [differently expressed power units]
T_j Time consumption of profit object j [hours]
C_{f_i} Fix cost of primary activity i [CZK]
C^{sa} Aggregated costs of secondary activities [CZK]

The four components can be merged into three components:

- assigned direct cost,
- allocated variable indirect cost, allocation is based on relative performance consumptions,
- allocated fix indirect cost, allocation is based on the relative time consumption:

$$C_j = C_j^d + \sum_{i=1}^{n} C_{v_i} \frac{P_{ji}}{P_i} + \frac{T_j}{\sum_{j=1}^{m} T_j} \left(\sum_{i=1}^{n} C_{f_i} + C^{sa} \right) \text{[CZK]} \quad (2)$$

The cost efficiency, i.e. the average cost of a primary activity (as service generator) can be calculated as follows:

$$c_i = \frac{C_i}{P_i} = \frac{C_{v_i} + C_{f_i}}{P_i} \text{[CZK/differently expressed power units]} \quad (3)$$

Where:

C_i Cost of primary activity i [CZK]

Hansen and Mowen (2007), Mocanu (2008) Langfield-Smith et al. (2015) and Watanapa, Pholwatchana and Wiyaratn (2016) emphasize that the activity-based costing method helps businesses to improve cost management through two views, namely cost and management view (process view).

Table 1

Main Warehouse Activities and Cost Drivers

Activities	**Cost Drivers**
Order receipt	Order volume and order source (electronic data interchange, fax, phone, internet, or post)
Unload incoming goods	Quantity and packaging (pallets or cartons)
Palletize	Quantity of cartons
Check incoming goods	Quantity and quality of supplier (including returns)
Put away incoming goods	Quantity and number of returns
Picking	Number of visits to pick location and percentage of back orders

Source: Gríful-Miquela (2001)

Gríful-Miquela (2001) stated in his article that the cost structure of logistics service providers to third parties was analysed with particular regard to warehousing. Activity-based costing has been shown to be a useful tool for assessing the operating costs of logistics service providers. Main warehouse activities and cost drivers are shown in Table 1.

3. Results and Discussion

The aim of this article is to use activity-based costing as a management method in a logistics service provider with regard to the cost management. The basic advantages of qualitative research are the detailed description and insight into the study of the issue, in addition it responds well to local situations and conditions and can search for local causal connections. The use of an activity-based costing method will be presented on a real case study based on the processes used in the decision-making process of a particular company.

The chosen logistics provider ensures transport services for many customers. In addition to transport, it also provides other logistics services. Such as activities related to warehousing, receipt of goods including their inspection, warehousing according to customer-required systems, or delivery of material and its transportation directly to the customer's production lines.

In recent years, logistics service provider (LSP) has been using a new approach to logistics warehousing cost calculations in connection with increased competition in the provision of logistics services. From the entire calculation system, it uses only preliminary calculations and, within the framework of the calculations, serves to support pricing decisions (for price negotiations, for price advocacy, for deciding whether LSP is interested in accepting the order, whether due to limited warehousing capacities for LSP interesting). The calculations always reflect customer requirements (the specific type and scope of service provided). There is a single cost structure in the calculation of the cost of warehousing (see Table 2). The calculation unit is always one product that customer requires to warehouse.

Calculation costs are structured to accommodate all customer requirements for the service provided.

The calculation includes the items: personal costs, handling equipment, transportation costs, facilities costs, information technology costs, other costs, operating costs and eventually overtime costs.

The LSP has monthly personal costs calculated per worker in a particular job position. In addition to wage costs, welfare costs, statutory insurance and liability insurance, costs include protective equipment, training, contributions to cultural and sporting events, and other company benefits.

Assignment of costs to handling equipment is based on customer requirements for product warehousing and necessary handling equipment that need to be handled with the product. The allocation of transportation costs to order is based on the fact that the LSP has the cost per km and the number of kilometres travelled by the various means of transport per month assigned transportation costs. The allocation of facilities costs is based on a cost per square meter and adequate warehouse equipment. Costs associated with information technology (IT) are focused on printing labels, printer traffic, cartridge costs, costs of IT connection, costs of maintaining IT and costs of communication.

Other costs consist of 100% external warehouse maintenance and the other costs include unexpected costs, which may be costs associated with the delay of the start of production or with the unexpected situations that may arise. Assignment of costs to operating is based on floor tape labelling in warehouse, operation margin in 1% and corporate margin in the height of 10% and the last item is insurance (liability).

Table 2

Logistics Cost Calculation of Warehousing and Other Logistics Services

4. Conclusion

The chain of logistics activities ensures the smooth running of the production process and logistics costs are associated with each logistics activity. These costs are not negligible items that affect to a large extent the overall profit or loss of

an enterprise. The need to monitor costs in terms of logistics activities is a prerequisite for identifying rationalization measures in logistics activities and optimizing the logistics costs of an enterprise.
In order to ensure the synchronization of the individual logistics processes, the availability of the information needed for the individual managerial levels, the assessment of the work of the employees, feedback from the customers and the flexible operation in the event of deviations from the financial plan, in today's competitive environment, provided the required information to the users, i.e. the management of the company. This article showed the possibility of using activity-based costing as the case study in the selected logistics service provider with regard to the warehousing.

SUSTAINABLE DISTRIBUTION LOGISTICS OF RETAIL CHAINS

Dana Sommerauerová[1], Jan Chocholáč[2], Michal Polák[3]
[1,2,3] University of Pardubice, Faculty of Transport Engineering, Department of Transport Management, Marketing and Logistics, Studentská 95, Pardubice 2, 532 10, Czech Republic

Abstract: Distribution logistics of retail chains is very specific, because the network of retail chains is usually very extensive and there are many constraints for distribution of goods, for example time windows of central warehouses (depots) and stores for loading and unloading, more deliveries within the same day to stores or distribution of objects of reverse logistics from stores to central warehouses. There are many flows between stores and central warehouses, for example product flows, information flows, financial flows, reverse flows etc. Sustainable distribution logistics should respect three pillars of sustainability, there are: economic, social and environmental pillars. Sustainable distribution logistics of retail chains should investigate the possibilities of streamlining with consideration to the pillars of sustainability. The article will focus on the distribution planning tools which are being used for planning of distribution logistics for retail chains. There are some algorithms of graph theory, for example: Vehicle routing problem with pickup and delivery with time windows. The aim of the article will be to find an algorithm for this type of exercise which will respect all defined constraints and pillars of sustainability for distribution logistics of retail chains. The algorithm will be simulated on a specific network of retail chain as a case study.

Keywords: distribution logistics, retail chain, vehicle routing problem, sustainability.

1. Introduction

The popularity of retail chains has grown in recent years among customers. Many retail chains have hundreds of stores and many central warehouses (depots). Demands on transport infrastructure and transport system as a whole are increasing. The intensity of traffic grows in the surroundings of individual stores, not only thanks to customers but also through the distribution logistics. The same applies for the surroundings of the central warehouses (depots) because hundreds of suppliers supply every day central warehouses and central warehouses deliver goods every day to hundreds of stores. It is also widely known that transport and distribution have a negative impact on the environment. This makes it necessary to pay maximum attention to distribution logistics. At the same time, greater emphasis is placed on sustainability issues through three pillars of sustainability and especially on the negative impacts of transport and distribution on the environment from the perspective of the environmental pillar of sustainability.

2. Theoretical Background of the Sustainable Distribution Logistics

Sustainable logistics is a research area developed since the 1990s according to Wiederkehr et al. (2004). Davis and Barekat (2002) stressed the terms like eco-logistics because these terms were increasingly used to define a sustainable environmental logistics. Schulte (1999) described sustainable distribution or sustainable distribution logistics as any means of transportation of goods in logistic chain with lowest possible impact on the environment and society. The term distribution includes according to the author the whole distribution process from storage, order processing and picking, packaging, improved vehicle loadings, delivery to the customer and reverse logistics. Sustainable distribution is based on three pillars: environmental pillar, economic pillar and social pillar. Faccio and Gamberi (2015) perceive logistic activities as the necessary condition for the harmonious growth of every urban area, even if they are also the main cause of pollution, noise and accidents. The rapid development of the demand for urban transportation has a negative impact on urban surroundings and on the environment (Wang et al., 2014). Faccio and Gamberi (2015) defined four groups of key players in the field of distribution logistics there are: retailers (stores etc.), carriers and warehouse companies, residents (inhabitants) and administrators (at national, regional and local levels). Karakikes and Nathanail (2017) stressed the importance of the urban distribution of goods because it is the main component of sustainable transport networks and one of the main contributors on traffic congestion and environmental pollution in the cities and agglomerations. Matsumoto et al. (2017) mentioned sustainable distribution or sustainable distribution logistics which considers both facility for distribution supply chain and also the transportation. Authors further emphasized the associated negative environmental impacts of distribution logistics and the need to use quality planning tools for distribution logistics. New challenges have been observed in models of vehicle routing problems which considered basic tools for implementing sustainable distribution channels in urban areas (Carrabs, Cerulli and Sciomachen, 2014).
Retail chains have usually a very extensive network which consists of depots (central warehouses) $D_1 \cdots D_n$ and customers (stores) $C_1 \cdots C_n$. The stores are supplied directly from direct suppliers $SD_1 \cdots SD_n$ or indirectly from depots. The depots are supplied from indirect suppliers $SI_1 \cdots SI_n$. Direct flows of the goods and indirect flows of the goods are depicted in the Fig. 1. Stores produce reverse flow especially transport units (pallets, crates, boxes etc.). These transport units are returned directly to the direct suppliers or indirectly to the indirect suppliers through the depots. The diagram of the distribution and reverse logistics of retail chains are depicted in the Fig. 1.

3. Methods and Data

Methods and data are presented in this chapter. The algorithm of heuristic method for Vehicle routing problem with pickup and delivery with time windows is presented firstly. Then VRP Spreadsheet Solver is paid attention because this Microsoft Excel Workbook is used to solve a case study which is theoretically described at the end of the chapter.
Algorithm of heuristic method for Vehicle routing problem with pickup and delivery with time windows according to Desaulniers *et al.* (2002) uses these types of variables: binary flow variables x_{ijk}, time variables T_{ik} (specifying when vehicle k starts the service at node $i \in V_k$) and variables L_{ik} giving the load of vehicle k after the service at node $i \in V_k$ has been completed. The formulation of Vehicle routing problem with pickup and delivery with time windows according to Desaulniers *et al.* (2002) is as follows formulas 1-15.

$$min \sum_{k \in K} \quad \sum_{(i,j) \in A_k} c_{ijk} x_{ijk} \tag{1}$$

subject to

$$\sum_{k \in K} \quad \sum_{j \in N_k \cup \{d(k)\}} x_{ijk} = 1 \,;\ \forall\, i \in P \tag{2}$$

$$\sum_{j \in N_k} x_{ijk} - \sum_{j \in N_k} x_{j,n+i,k} = 0 \,;\ \forall\, k \in K, i \in P_k \tag{3}$$

$$\sum_{j \in P_k \cup \{d(k)\}} x_{o(k),j,k} = 1 \,;\ \forall\, k \in K \tag{4}$$

$$\sum_{i \in N_k \cup \{o(k)\}} x_{ijk} - \sum_{i \in N_k \cup \{d(k)\}} x_{ijk} = 0 \,;\ \forall\, k \in K, j \in N_k \tag{5}$$

$$\sum_{i \in D_k \cup \{o(k)\}} x_{i,d(k),k} = 1 \,;\ \forall\, k \in K \tag{6}$$

$$x_{ijk}\left(T_{ik} + s_i + t_{ijk} - T_{jk}\right) \leq 0;\ \forall\, k \in K, (i,j) \in A_k \tag{7}$$

$$a_i \leq T_{ik} \leq b_i;\ \forall\, k \in K, i \in V_k \tag{8}$$

$$T_{ik} + t_{i,n+i,k} \leq T_{n+i,k};\ \forall\, k \in K, i \in P_k \tag{9}$$

$$x_{ijk}\left(L_{ik} + l_j - L_{jk}\right) = 0;\ \forall\, k \in K, (i,j) \in A_k \tag{10}$$

$$l_i \leq L_{ik} \leq C_k;\ \forall\, k \in K, i \in P_k \tag{11}$$

$$0 \leq L_{n+i,k} \leq C_k - l_i;\ \forall\, k \in K, n+1 \in D_k \tag{12}$$

$$L_{o(k),k} = 0;\ \forall\, k \in K \tag{13}$$

$$x_{ijk} \geq 0;\ \forall\, k \in K, (i,j) \in A_k \tag{14}$$

$$x_{ijk} binary; \forall k \in K, (i,j) \in A_k \tag{15}$$

The linear objective function (1) minimizes the total travel cost. Constraints (2-3) impose that each request is served exactly once and by the same vehicle. Constraints (4-6) characterize a multi-commodity flow structure and ensure that each vehicle k starts from its origin depot $o(k)$ and terminates its route at its destination depot $d(k)$. Compatibility requirements between routes and schedules are handled by constraints (7) and (8) are the time window constraints. For each request, constraints (9) force the vehicle to visit the pickup node before the delivery node. Constraints (10) express the compatibility requirements between routes and vehicle loads, while (11-12) the vehicle dependent capacity intervals at pickup and delivery nodes. The initial vehicle load is imposed by (13), and no negativity and binary requirements are given by (14-15). Constraint sets (3) through (15), as well as the objective function, are separable for each vehicle $k \in K$ (Desaulniers *et al.,* 2002).
The algorithm for Vehicle routing problem with pickup and delivery with time windows is solved in the Microsoft Excel workbook "VRP Spreadsheet Solver" which is an open source unified platform for representing, solving and visualizing the results of Vehicle Routing Problems. VRP Spreadsheet Solver uses public Geographical Information Systems (Bing Maps) and metaheuristics. The author of the "VRP Spreadsheet Solver" is Güneş Erdoğan and its scientific area covers exact and heuristic optimization methods, ambulance location problems, traveling salesman problems, vehicle routing problems and scheduling problems (Güneş, 2018).
Güneş Erdoğan and other co-authors are the authors of the following scientific articles, for example A Note on a Polynomial Time Solvable Case of the Quadratic Assignment Problem (Güneş and Tansel, 2006), A Branch-and-Cut Algorithm for Quadratic Assignment Problems Based on Linearizations (Güneş and Tansel, 2007), Ambulance Location for Maximum Survival (Erkut, Ingolfsson and Güneş, 2008), Computational Comparison of Five Maximal Covering Models for Locating Ambulances (Erkut *et al.,* 2009), The Traveling Salesman Problem with Pickup and Delivery and First-In-First-Out Loading (Güneş, Cordeau and Laporte, 2009), Scheduling Ambulance Crews for Maximum Coverage (Güneş *et al.,* 2010), The Attractive Traveling Salesman Problem (Güneş, Cordeau and Laporte, 2010), The Traveling Salesman Problem with Pickups, Deliveries and Handling Costs (Battarra *et al.,* 2010), A Branch-and-Cut Algorithm for the Non-Preemptive Capacitated Swapping Problem (Güneş, Cordeau and Laporte, 2010), Formulations and Branch-and-Cut Algorithms for the Generalized Vehicle Routing Problem (Bektaş, Güneş and Ropke, 2011), Modelling and solving an m-location, n-courier, priority-based planning problem on a network (Güneş, Tansel and Akgün, 2012), Metaheuristics for the traveling salesman problem with pickups, deliveries and handling costs (Güneş et al., 2012), The Orienteering Problem with Variable Profits (Güneş and Laporte, 2013) and Exact Algorithms for the Clustered Vehicle Routing Problem (Battarra, Güneş and Vigo, 2014).
The case study will be used for application of Vehicle routing problem with pickup and delivery with time windows in the real retail chain. The case study is the method of the qualitative research based on the study of one or a small amount of situations for application of the findings for the similar cases according to Nielsen, Mitchell and Nørreklit (2015).
The case study data represent the data of the real retail chain in the Czech Republic, but this case study is limited to just one depot (central warehouse) which is located in the Praha-východ and the case study is limited for the one round of distribution within the day. The visualization of the depot and customers (stores) is in the Fig. 2.

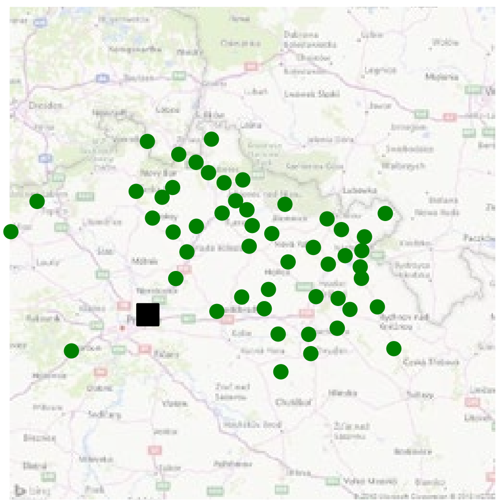

Fig. 2.
The Visualization of the Depot and Customers (Stores)

VRP Spreadsheet Solver applied these limited conditions for this case study: one depot, fifty customers, the fastest route in Bing Maps, the average vehicle speed was set to 70 kilometers per hour, homogenous car fleet with maximum capacity thirty three pallet space, hard time windows type, service time in depot was one hour and customer service time was half an hour.

4. Results

Results of the vehicle routing problem with pickup and delivery with time windows for the case study are presented in the Table 2, there are twenty three vehicles with defined routes to the customers. Every vehicle starts and ends in the depot. The number in brackets indicates the number of pallet space for pickup and delivery in the depot and for each customer. The vehicle 17 serves only one customer (40), other vehicles serve from two to three customers. Three customers serve vehicle number 3, 4, 16, 18 and 21. This is the optimal solution according to entered inputs with the use of VRP Spreadsheet Solver.

Table 2

Solution of the Case Study With Individual Routes and Information About Pickup and Delivery

5. Conclusion

In the future can be expected a further increase of traffic intensity due to population growth and population's increasing demands on mobility. The growing boom of e-commerce will lead to greater pressure on distribution logistics and the rising popularity of retail chains, rising sales and higher sales volumes increase the demand for distribution logistics of retail chains. On the other hand, it is necessary to emphasize the need to reduce the negative impacts of transport. One of the potential to reduce the negative impacts of distribution logistics is to use efficient planning tools to optimize the distribution logistics of the retail chain.

OPEN ACCESS INTERMODAL TERMINALS FOR GREENER LOGISTICS SERVICES

Magdalena Klopott[1]**, Joanna Miklińska**[2]
[1,2] Gdynia Maritime University, Department of Logistics and Transport Systems, Poland

Abstract: The paper builds upon prior research on the potential for the greening of transport and logistics services on the Polish market. The shift from road to rail has often been put forward as the most favourable measure to meet the environmental goals. Although the Polish intermodal transport (rail-road in particular) has been steadily growing, compared to other European countries and taking the existing infrastructure into account, its share could be higher, and the rate of its growth could be faster. Therefore, we conducted a Delphi study to identify the barriers to the development of intermodal transport in Poland. Issues concerning intermodal terminals were consistently indicated as one of the main obstacles, thus becoming the primary focus of the paper. Using the Delphi method, we further determined that the main problems with intermodal terminals are insufficient number and non optimal spatial distribution, inadequate technical standards (IT and equipment in particular) as well as issues with ownership and management structures. The latter are elaborated to a greater extent, showing that the open access to terminals is crucial to ensuring better utilisation of intermodal terminals and further development of rail-road transport. We also present the ongoing process of making the access to terminals open to all railway undertakings, what activities have been taken and what are the experiences so far. The findings are not limited to the Polish market, but have broader implications and can help in understanding the phenomena found in other transport and logistics markets, especially those still developing or less mature.

Keywords: intermodal transport, intermodal terminals, open access terminals, green transport, green logistics.

1. Introduction

The transport and logistics (T&L) industry is a considerable source of negative externalities and its contribution to GHG emission is also substantial. In the face of global environmental problems and climate change every effort (of countries, companies, individuals) towards the greening of T&L services is needed in order to meet targets implied by national or global agreements on preventing air pollution.

Recent studies by Klopott and Miklińska (2017a and 2017b) on the state of greening of the T&L services in Poland revealed that the process of "greening" is at the very early stage of its development and its pace is unsatisfactory. Authors identified the scope and types of green initiatives and practices implemented by logistics services providers (LSPs) on the Polish market and examined the factors behind the (non)implementation of green solutions. They also focused on the purchasing phase and explored the correlation between green requirements of customers, if any, and the readiness of logistics providers acting in Poland to satisfy such needs. These studies revealed, among others, that (Klopott & Miklińska, 2017a and 2017b):

- there is a rather low green awareness among stakeholders of the T&L market in Poland,
- the demand for green transport and logistics services is not noticeable,
- there is a shortage of green initiatives on the Polish market implemented by logistics services providers (LSPs),
- there is a lack of readiness (organisational, technical, as well as financial) to fulfil the green requirement of LSPs' customers,
- influence on the environment as a buying criterion is a factor of no or very low significance,
- the green criterion is not considered by LSPs when choosing a subcontractor, unless it is expressly required by the customer,
- only a small number customers noticed the potential for intermodality and requested reducing the share of road transport in favour of railways,
- LSPs rarely encourage their customers to choose a greener transport mode and to take advantage of intermodal solutions.

These findings cannot be disregarded, considering the projected rapid development of the Polish T&L market and its high share in the total EU market (e.g. in 2015, this market was ranked as 7th biggest in Europe (Kille et al., 2015)). Especially interesting are the findings regarding the intermodal transportation. Indeed, despite the potentially favourable conditions, the share of intermodal transport in Poland is disappointingly low and road transport is still predominant. There are many reasons and explanations as to why the modal shift has not yet occurred, and the issue concerning intermodal terminals is one of them. Therefore, the aim of this paper is to highlight the status quo of intermodal terminals in Poland and to present the ongoing process of making the access to these facilities open to all railway undertakings, in order to foster better utilisation of terminals. This is important to ensure the growth of intermodal transport share and, thereby, the development of green logistics services in Poland.

2. Intermodal Transport in the Greening of T&L Services

[1] Corresponding author: m.klopott@wpit.am.gdynia.pl

Transport operations account for a large share of logistics systems' emissions (Eng-Larson&Kohn, 2012). According to the European Environmental Agency, the EU transport sector is still responsible for 46% of total EU-28 emissions of NO_x and constitutes a rising source of GHG emissions that in 2015 exceeded 1990 levels by 21% (EEA, 2015). On a global level, the international trade-related freight transport had a carbon footprint at around 1600 Mt CO_2 emissions from fuel burn in 2015, and it is projected that, along with rising volumes of transported cargoes, CO_2 emissions could increase by 120% by 2050 if no reduction measures are taken (OECD/ITF, 2017). The road freight transport was responsible for a large portion of these emissions (at around 40 %) (OECD/ITF, 2017).
Within the array of suggested measures to make transport and logistics greener, and to reduce their environmental impact, is a shift to intermodal transportation (e.g. McKinnon, 2008; European Commision, 2001 and 2011; Eng-Larson & Kohn, 2012). The potential of a modal shift from road transport to less polluting modes has been raised by European politicians since the late 1990s. The modal switch was presented as a promising way to reach the target reductions in CO_2 emissions from transport operations agreed under national and international agreements (see e.g. European Commission, 2001).
However, despite political ambitions and substantial EU financial support (with a flagship Marco Polo programme), transport statistics do not mirror these efforts and only a minor progress has been observed. Road transport continues to dominate the transport market in Europe, accounting for nearly 75 % of the total inland tonne-kilometres performed, while rail transport for a little above 18 % and inland waterways for about 6 % (Eurostat, 2016). The share of road and rail transport (28 EU countries) has remained almost unchanged since 2009: road transport decreased by 2.2 %, while rail transport recovered slightly, increasing by 1.5%, compared to 2009 (Eurostat, 2016). There is a number of explanations as to why the intermodal transport has not yet achieved a desired share, with the low quality of intermodal service supply and demand inertia being among the most commonly cited (e.g. McKinnon, 2008; Eng-Larsson & Kohn, 2012).

3. Intermodal Transport in Poland

3.1. General Overview

Since 2007, the intermodal transport (rail-road in particular) in Poland has been growing steadily, although the pace of its development is unsatisfactory. The total volume of transported cargo increased from 4,8 million tonnes in 2008 to 14,7 million tons in 2017 (UTK, 2018), which represents the growth at CAGR 13,2 %. In 2017, for the first time in history, the total volume of cargo transported by rail operators surpassed 1 million of intermodal units, mostly containers, thus marking an increase of CAGR 10,9 % from 2008 (Figure 1). Nevertheless, the share of intermodal transport in overall railway freight transport remains very low, accounting for 4.53 % and 8.8 % (measured by transport output) in 2011 and 2016, respectively. It needs to be emphasized that the related European average (by transport output) was at 17.6% already in 2010 (UTK, 2012, 2017). Nevertheless, the number of rail carriers (rail undertakers) has been consistently increasing: from 6 in 2007, 9 in 2012, to 18 in 2017 (UTK, 2018).

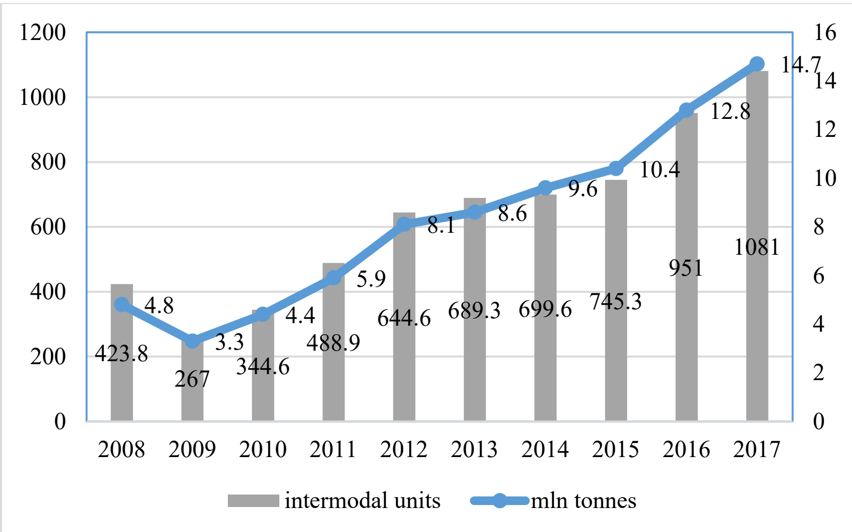

Fig. 1.
The volumes of intermodal freight transport in Poland over the period 2008-2017 (in million tonnes and number of intermodal units)
Source: own elaboration based on the Office of Rail Transport data (UTK, various issues)

At present, there are 19,330 km of railway lines in operation (fourth rank in Europe), of which 62% are electrified (higher than European average for 22 EU countries - 54,6%) (IRG-Rail, 2017). However, the length of railway lines has been significantly reduced within the past 20 years, and ca. 4 755 km of railway lines have been withdrawn from operation (Miklińska, 2017). About 98% of railway networks are standard gauge lines (1435 mm), while approximately 2% are wide track (1520 mm). The average density of railway lines in 2016 amounted to 6,1 km/100km^2 (CSO, 2017). The majority of railway lines (95,8 %) are managed by the main infrastructure manager, PKP PLK (IRG Rail, 2017) who provides conditions for rendering services in intermodal transport (being responsible, e.g., for modernisation of railways and imposing charges on rail carriers).

Although the Polish intermodal transport has been steadily growing, compared to other European countries and taking the existing infrastructure into account, its share and the rate of its growth are disappointing. As mentioned above, Poland has a sufficient length of railway lines (9,4 % of all European railway lines in 24 EU countries), but the share in total volume of cargo transported by intermodal transport within the EU (measured by transport work) was only 3,56 % in 2011. To compare: Germany accounts for 18,9 % of railways in length, but its share in intermodal freight transport is considerably higher (about 13 times as high), going above 47,53% in 2011 (UTK, 2013; Eurostat, 2016; IRG Rail, 2017). Therefore, there are reasonable grounds to believe that further and faster development of intermodal freight transport in Poland can potentially be achieved, and solutions to support its growth should be sought.

3.2. Main Barriers to Better Utilisation of Intermodal Transport in Poland

In order to identify the barriers that hinder satisfactory utilisation of intermodal transport in Poland, an empirical study using the Delphi method was conducted (Considering the limited length and the main purpose of the paper, an in-depth elaboration of the study, its methods and research proceedings have been omitted). The Delphi method can be used to help identify problems and their potential solutions, in forecasting, in decision-making, as well as to set goals and priorities (Dalbecq et al., 1986), being a suitable technique that allows to aggregate expert opinions on a given topic. 16 experts were chosen to participate in the study, in such a way as to reflect opinions of different stakeholders related to the transport and logistics market who are involved (directly or indirectly) in the intermodal operations. The coefficient of variation was used as a measure of consensus as well as stability, and, as suggested by English and Keran (Van der Gracht, 2012), its value at or below 0.5 was established as a cut-off point, indicating the acceptable degree of consensus (no need for additional round). Finally, the Delphi process was divided into three rounds: Round 1 took place early October, Round 2 - mid-November, and Round 3 - late November and early December, all in 2017.

The experts achieved a very high level of agreement for a number of factors hindering better utilisation of intermodal transport in Poland. Those with the highest scores of consensus were listed below and divided into seven groups for more clarity. These groups were: liner infrastructure, nodal infrastructure, rolling stocks, transport policy, market & organisational issues, costs & prices, awareness & cooperation.

Linear infrastructure:

- The poor condition of railway infrastructure, being a consequence of years of neglect (and inherited after the period of the centrally planned economy). It is only in recent couple of years that rail infrastructure has been modernized and its condition is slowly but systematically improving, although it still lags behind Western European standards.
- Investments in road infrastructure (increasing density of motorways) have improved conditions for road freight services.

Nodal infrastructure:

- An insufficient number and nonoptimal spatial distribution of intermodal terminals in Poland to ensure growth of intermodal transport in different parts of the country and on different routes.
- An inadequate technical standard of many intermodal terminals. It refers, especially, to the limited handling and storage capability, stacking and handling yard pavement, length of railway trucks, handling equipment.
- The fragmented ownership and management structures of intermodal terminals is an impediment to coordination of intermodal services.
- The lack of non-discriminatory rules with regard to access to intermodal terminals to all railways undertakings.
- Uncoordinated process of development of intermodal terminals. As a result, there are some locations where there were too many of them (all were under-performing).
- The lack of dedicated IT systems coordinating utilisation of inland intermodal terminals.

Rolling stocks:

- There is a lack of appropriate rolling stocks, while the condition and age of the existing ones is very poor.
- In particular, there is a lack of special locomotives of relevant parameters dedicated to the intermodal transport, as well as a lack of a special railways wagons.

Transport policy:

- In the long term, the lack of consistent and coherent policy as well as the lack of a comprehensive vision with regard to intermodal transport development; empty promises in the national strategy for transport development, which did not translate into action.

- The lack of stability of policy of intermodal transport development (e.g. with regard to financial support (subsidies) for intermodal alternatives; no one knows whether it will continue or not).
- The lack of competent and continued (i.e. regardless of changing central governments) administration body responsible for development of intermodal transport.

Costs & prices:

- Too high track access charges paid by railway undertakings; the level of these charges is considerably higher compared to road transport as well as to track access charges in other countries.
- The price for intermodal carriage is not attractive for shippers, and, as it is the main criterion for choosing the mode of transport – intermodal is at a disadvantaged position.
- Intermodal "subsidies" (rebates) are too low to counterbalance the cost differences between modes (rail-road); the selections of beneficiaries of intermodal "subsidies" is arguable, and it is a consequence of a lack of a clearly defined meaning of intermodal transport (and intermodal terminal as well).

Market & organisational issues:

- The lack of sufficient flows of goods that may enforce the use of intermodal transport.
- The quality of intermodal services is insufficient; to some extent this is a result of the condition of linear infrastructure (speed limitations; limited permissible axle load; too slow timetable speed).
- The lack of proper organisation of road feeder services to and from intermodal terminals.
- Railway carriers fail to adapt to contemporary market structures as well as to customer demands.

Awareness & cooperation:

- The environmental awareness is almost non-existent, except some global LSPs; the eco-awareness diminishes against the issues of costs and profitability.
- Reluctance of different stakeholders to cooperate and the lack of mutual trust.
- Mental barriers and habits, reluctance to changes among various stakeholders, which are not always rational.

The issues concerning intermodal terminals in Poland have been consistently indicated among the main obstacles, and therefore, they require further elaboration.

5. Intermodal Terminals in Poland and the Issue of “Open Access”

Over the past years, the number of intermodal terminals in Poland has increased to more than 30; on average, there is one terminal per 10,000 km^2 of the country’s area. In Western European countries, this figure is higher, at 4.2 terminals per 10 000 km^2 (in Germany more than 4, in Belgium over 7, and in the Netherlands over 11, per 10 000 km^2) (UTK, 2012 and 2016). As mentioned previously, Delphi panellists indicated problems with the spatial distribution of these terminals, also pointing to the inadequate technical standard of many of them. Indeed, a significant number of intermodal terminals in Poland, especially older ones or recently modernized, fail to meet Western European standards, making it impossible for them to handle larger flows of containers or other intermodal units. A diverse ownership structure of intermodal terminals in Poland constitutes a significant obstacle in their effective utilisation. These terminals are owned or managed by various entities; in Poland by: intermodal operators, railway carriers, infrastructure managers, operators of sea container terminals, companies with more shareholders, and others. A similar situation exists in other European countries (UIRR, 2016). The issue of terminal ownership is also directly linked to their funding, as various entities have access to various sources of financing. This may result in uneven terminal development on a national scale. An UIRR report emphasizes that: “The diverse ownership and financing background of transhipment terminals mean that they constitute a unique category of transport infrastructure” (UIRR, 2016). Therefore, intermodal terminals should be of special interest. Without their sufficient number and spatial distribution, as well as without open access provided to all operators, further development of intermodal transport will be jeopardised. Hence, it is necessary to take all possible actions leading to a better utilisation of existing facilities, but also in line with the EU policy. Already in the EU White Paper 2011, it was stressed that: „Infrastructure shapes mobility. No major change in transport will be possible without the support of an adequate network and more intelligence in using it” (European Commission, 2011). Although this statement refers to the mobility of people, its meaning can be extended to freight terminals and cargo transport. The intelligent utilisation of the existing intermodal terminals may be facilitated with the policy of "open access" in place.

The issue of "open access" as a response to problems related to the utilisation of intermodal terminals is not suggested only by Delphi panellists, but it is also the opinion of specialists from the European intermodal sector. In a 2014-2015 UIRR report, we read: “The lack of a European definition for "open access terminal" - ideally contained in legislation, as well as the conditions that they must fulfil, creates an uncertain situation as today each Member State may, or may not, set different requirements. Subsequently, CT stakeholders must "learn" the conditions from terminal to terminal and from country to country (…) The differences in the conditions of accessing terminals are emerging as an obstacle to devising new CT connections” (UIRR, 2015, 11).

In order to redress this situation, some steps were initiated at the EU level in 2017. Then, a new regulation regarding service facilities was adopted, i.e. the Commission Implementing Regulation (EU) 2017/2177 of 22 November 2017 on access to service facilities and rail-related services. It constituted a kind of general terms also for freight terminals and other categories of rail service facilities. These rules must be complied with by 1 June 2019 (UIRR, 2018). In Poland, new solutions regarding access to the railway infrastructure facilities have been proposed by the amendment to the Rail Transport Act of 2016, which came into force in 2017 (Act, 2016). The facilities listed in the Act include, among others, freight terminals and hence also intermodal terminals.

A question arises as to what conditions must be met for a railway undertaking to obtain access to an intermodal terminal and how is this access regulated in Poland. In accordance with the provisions of the abovementioned Act on railway transport, the manager of the service infrastructure facility prepares its statute, which specifies whether the facility is intended to be shared or not. The facility may not be shared only when it has not been in use. Rail carriers, including those from other Member States, have access to infrastructure facilities on equal and non-discriminatory terms. In order to acquire the right to access an infrastructure facility (e.g. an intermodal terminal), a railway undertaking must conclude an agreement with the terminal operator, specifying the rights and obligations of both in the scope of the services provided. Further, the operator of the facility also develops Regulations for access to the facility, in which the terms of making the terminal available, technical conditions, and the amount of charges are stipulated, among others. These Regulations must be published on the operator's website. The national register of the service infrastructure facilities (including intermodal terminals) is maintained by the President of the Office of Rail Transport (ORT - Polish abbreviation UTK) and it contains information about the owner of the facility, the facility manager and the operator, the railway network to which the facility is connected, as well as the scope of services (Act, 2016). Currently (July 2018), 37 intermodal terminals are listed on the ORT website (Table 1), along with a map of terminals (and other service facilities) in Poland (Fig. 2) (terminals marked by blue boxes) (UTK website, 2018a).

Fig. 2.
Map of intermodal transport facilities in Poland
Source: UTK website, 2018b <http://www.utkgik.home.pl/mapa_obiektow_kolejowych/>

In reference to the data presented in Table 1, it should be added that there are substantial differences between terminals regarding lifting and handling equipment. The biggest intermodal terminals, especially those located in seaports, are very well equipped, such as with: Shore to Ship Super Post Panamax Cranes, Shore to Ship Post Panamax Cranes, Rubber Tired Gantry Cranes, Internal Movement Vehicles, forklifts etc. However, there is still a lot of terminals (13 out of 37) characterized by a very basic handling equipment, e.g. with just Reach Stackers (sometimes only 1 or 2 of them); in the case of three terminals, there is no information on the ORT website regarding the handling equipment that they use.

Considering the specificity of intermodal transport in Poland, equipment of terminals and services offered concern, mainly, the handling of containers, but also, to a lesser extent, swap bodies, big bags, iron ore, grain or dangerous goods.

The biggest and most modern are terminals provide a bigger range of services and more regular connections to other intermodal facilities. Apart from basic services such as loading and discharging or storage of containers, these terminals offer: the stuffing and stripping of containers, warehouse services, customs clearance, weighing (VGM/SOLAS), container repairs, depot services, and last mile delivery services. Some of them work on a 24-hour basis, 7 days a week, and some on business days only (7 a.m. to 3 p.m. or later), holidays excluded (UTK website, 2018a; Terminals Catalogue 2018). Basic information about intermodal terminals are gathered in Table 1.

Table 1
Intermodal terminals in Poland

No	Name of the terminal	Owner/manager	Total area/the current maximum annual transshipment capacity/storage area	The number and size of railway tracks for loading and unloading
1.	BCT – Baltic Container Terminal Ltd.	International Container Terminal Services, Inc.	66,2 ha/1 200 000TEU/ 20 000+storage yards for 6500 cars	3x675m 2x300m
2.	Gdynia Container Terminal S.A.	Gdynia Container Terminal S.A./ HPH GROUP, CK HUTCHISON HOLDINGS	19,6 ha/636 000TEU/ 2 536 slots for 20ft/ max storage capacity 112 000TEU	4 tracks, 520m 3 tracks,638m
3.	Deepwater Container Terminal Gdańsk	DCT Gdańsk S.A.	71 ha/3 000 000 TEU/ 55 000 TEU	4x618m

Source: own elaboration based on: UTK website, 2018a, Intermodal terminals, <https://www.utk.gov.pl/pl/dostep-do-infrastruktur/dostep-do-infrastruktur/mapa-obiektow-infrastru/terminale-intermodalne>; Terminals Catalogue 2018.

How does the implementation of new legal provisions work in practice? Operators of intermodal terminals in Poland, in accordance with legal provisions, were required to publish the terminal regulations on their websites by 9th December 2017 and most of them have fulfilled this obligation. Moreover, they were also obliged to submit the facility to the register of the President of ORT. According to information provided by representatives of ORT during the intermodal conference held in Gdańsk in April 2018, there are still managers who have failed to submit their facility or have provided incomplete information (Kozłowska UTK, 2018). The process of creation of the register of infrastructure facilities continued until the end of June 2018 and it currently contains information about 37 intermodal terminals (UTK website, 2018a).

It should be emphasized that the President of ORT ensures the non-discriminatory and equal treatment of carriers by terminal operators. In the case where e.g. the Regulations of a particular facility do not meet the requirements of the Act, and this fact results in difficulties for the railway carrier to obtain access to the terminal, the carrier may submit a complaint to the President of ORT (UTK website, 2018a).

6. Conclusions

Intermodal transport in Poland develops slowly but steadily. However, it is difficult to specify to what extent exactly stakeholders take advantage of the existing potential in order to utilise the intermodal alternative on a larger scale and offer more environmentally friendly T&L services. The findings derived from the Delphi study confirmed that there are still a lot of obstacles hindering the desired development of this market and intermodal terminals are among the most important ones.

A large number of terminals in Poland differs unfavourably from standards met in Western European terminals, requiring substantial improvements (and, in consequence, a significant financial contribution). It is also necessary to undertake other measures, e.g. based on a wider cooperation on the intermodal market participants, which could lead to a better utilisation of terminals in the future.

Recent changes in the policy regarding intermodal facilities and making them "open" are an example of such measures. Given that the lack of open access to terminals was considered problematic by all Delphi panellists and achieved a high score of consensus, it may be assumed that this measure, although taken with much delay, was welcomed with enthusiasm by the intermodal transport stakeholders. The process of making terminals in Poland open is ongoing, but this is only the first step on the long road to improvement and results are difficult to forecast. Undoubtedly, however, a change in perception with regard to this issue can be observed.

It also must be recognized that potential development of intermodal transport may also bring new challenges for intermodal terminals, as rising cargo handling volumes would require further improved cooperation and dedicated IT solutions.

The findings of this study are not limited to the Polish market, but have broader implications and can help in understanding the phenomena occurring in other transport and logistics markets, especially those still developing or less mature.

It would be interesting to investigate in the future the influence of the new "open access" policy on operational performance measures of terminals (e.g. changes in handling volumes, number of connections/calls, number of rail undertakings with access to terminals), as well as to research to what extent it could influence the process of greening T&L services.

Abstract: In goods delivery process there are lots of activities such as: order processing, order preparation, transport, control of the delivered goods, etc. In this paper, process of goods handover at the delivery point was analysed in detail. Analysed data was collected from a logistics provider, who is supplying markets at the gas stations, for a period of 22 days. During these days, provider had 1783 deliveries. Based on duration of certain activities it was concluded that the most savings can be achieved by optimizing delivery time. Main cause for longer handover is the large number of order lines, as well as quality and quantity controls. Efficiency of this process is crucial since saving time during this process, saves cost as well. In order to determine whether process is statistically controlled, in this paper, Statistical Process Control (SPC) was used. When delivering, goods are placed on pallet which must be checked at the delivery point. Processes of quality and quantity control are done simultaneously with goods handover, and were also analysed. Process was controlled in most of the analysed days, except one when handover time was longer than usual and influenced on process to go over the control limits. Determined day when uncontrolled process occurred was than analysed in detail. Some corrective-preventive actions in order to improve delivery process are also defined. Based on the results it can be concluded that the proposed methodology is very useful for improving process time.

Keywords: Statistical Process Control, control chart, unloading time, quality control, quantity control.

1. Introduction

Distribution process besides picking is one of the most intense and most demanding processes since lots of resources in terms of people and vehicles are required. Unlike picking process, distribution is characterized by the fact that it allows direct contact with the customers, which based on this process can create perception of the quality of the provided service, since everyone wants the right goods, in the right amount, in the right place and in the right time. Based on previous sentence it can be concluded that time component is one of the most significant in distribution process. For this reason monitoring distribution time component is of great importance, since the delay in distribution causes a number of problems such as complaints, the dissatisfaction of the customer, additional costs, creating wrong perception of the service quality and others.

Distribution is characterized by a series of interconnected and conditioned activities and processes. These processes are receipt of the order and processing of the same, issuance of the picking order, preparation of goods and delivery of the goods to the customer. Monitoring realization time of the above mentioned processes is of great importance if increased efficiency of the process and cost savings are desired. In this paper, distribution times from the retailer's distribution centers (DC) to the stores on gas stations were observed. The observed times were then analyzed using a control chart to determine on which days an uncontrolled process occurred. After the application of the control chart for all observed days, the same was applied for the day that was uncontrolled to determine when the uncontrolled process occurred during the day. Reasons for the longer distribution time can be numerous and will be analyzed in this paper.

The paper is organized as follows. In first chapter a problem description is provided. In the next chapter tools for time controlling were analyzed. In the final chapter results of the analyzed problem are provided as well as prepositions for the process improvement. At the very end of the paper final conclusions and directions of the future research have been made.

2. Problem Description

The distribution process represents a link between ordering and goods delivery, which is realized through its channels. A distribution channel can defined as a system of individuals and organizations aimed at directing the flow of goods and services from producers to the consumers. Depending on the relationship between the seller and the buyer, there are different types of distribution channels. The basic type of distribution channel is a direct channel where there is no intermediary between the manufacturer and the end consumer. This type of distribution channel represents the shortest and simplest form of product distribution. Mostly smaller and more frequent deliveries are realized through this type of channel. The next type of distribution channel implies the participation of distributors in distribution process through manufacturer's network. The characteristic of this type of channel is that manufacturer has a certain amount of final products in stock in their distribution centers, from where it is then transported to the retail. It is important to note that deliveries to the distribution center are carried out with larger vehicles of higher capacity with homogeneous load while distribution is carried out with vehicles of less capacity. The disadvantage of using this type of channel lies in the fact that all logistics resources are owned by the manufacturer. As a mediator, beside distribution network of the manufacturer, the distribution network of seller can be present, which is the third type of distribution channel. This type is identical to the previous one with only one difference, and that difference is that all logistics resources are owned by

[1] Corresponding author: m.kilibarda@sf.bg.ac.rs

the seller. The disadvantage of this type of channel is reflected in lower dedication in core business by the seller. The fourth type for intermediary has wholesalers which are purchasing products from manufacturers and then selling them to the retailers. In order to eliminate lack of the third type of distribution channel a 3PL provider is introduced as an intermediary who carries out logistics activities for the manufacturer. The advantage of this type of channel is reflected in the fact that a logistics provider can perform distribution at a lower cost. The last type of channel as a intermediary has a broker. This type is rare and is mostly used in trading channels (Andrejić, 2015).

As previously mentioned, subject of this paper is distribution of the goods to the markets on gas stations. The distribution process itself is organized as follows. Before the distribution process there are certain processes that precede and must be realized in order to realize the distribution process. Namely the entire process begins by customer sending its order in accordance with its needs. Upon receipt order is processed and picking order is issued. After picking the goods are loaded and are distributed to the end-users. The described processes are shown in Figure 1.

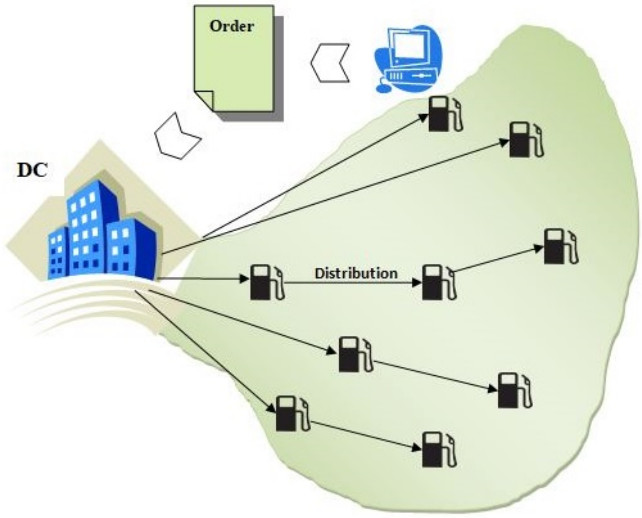

Fig. 1.
Distribution process

In the analyzed case, it can be concluded that this is a type of distribution channel where the network of the seller appears as an intermediary. In this case, the goods are being delivered from 5 DCs to 300 markets on gas stations. In the process of delivery 100 vehicles of different categories and capacity are used.

3. Tools for Time Control During the Process of Delivery

The tools for monitoring certain distribution processes are numerous, however in most cases the statistical process control (SPC) is used in the literature where the process capability indices are calculated and the control chart is used to visualize the uncontrolled process. In logistics, control chart can be used to monitor numerous parameters, both time as in this case, as well as other parameters. A common goal in all these different applications is to improve the process and to make it more efficient. Thus Sousa et al. (2017) applied SPC to improve the production process and thereby improve product quality. By applying these tools, the authors came to the conclusion which are the main causes of product quality variation. The SPC can also be used to determine capability of certain processes (Kilibarda and Andrejić, 2014). Costantino et al. (2015) applied SPC and control charts to improve inventory replenishment in supply chain thus lowering uncertainty and improving supply chain performance. In this paper SPC and control charts were also used since the aim of the paper was to determine if and when uncontrolled process occurred, and to determine capability of delivery as well.

3.1. Statistical Process Control (SPC)

Statistical Process Control (SPC) represents tool used to determine process capability, in order to improve quality of the product thus lowering cost of the production lower quality products or damaged ones. Three methods are used to determine process capability: diagram of dispersion, control charts and index method used to represent process capability. Applying the SPC determines whether the process is statistically controlled or it is necessary to apply some of the corrective-preventive actions in order to improve process. Diagram of dispersion and control charts give a graphic representation of the process control using control limits, given that if the process is within the control limits, then it is also controlled. Otherwise it is uncontrolled process that needs to be monitored and improved. In contrast to these methods, the index method examines the ability of the process over a set of indexes such as:

- Potential Capability index - Cp;
- Process Capability index - Cpk.

Relationship between these two indexes is shown in Figure 2.

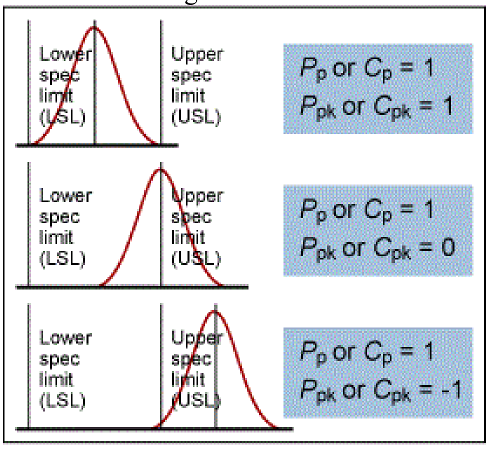

Fig. 2.
Relationship between Cp and Cpk
Source: (*Berardinelli, 2018)*

It is important to note that when calculating the Cp and Cpk indexes, following conditions must be met: the observed sample is large, normal distribution of the sample, the process is stable. When these conditions are not met, the obtained data are not valid.
Cp and Cpk indexes in this paper are calculated using formulas (1) and (2) shown below. Based on formula (1) it can be concluded that Cp index was obtained by dividing the difference between the upper (UCL) and the lower (LCL) control limits by 6σ. Sigma in the formulas represents a standard deviation that is counted for the observed sample. In the case of Cpk index a minimum value is obtained, either as a fraction of a difference between the upper control line and mean value divided by 3σ or as a difference between the mean value and lower control line divided by 3σ.

$$Cp = \frac{UCL-LCL}{6\sigma} \quad (1)$$

$$Cpk = \min\begin{cases}\frac{UCL-\bar{x}}{3\sigma}\\ \frac{\bar{x}-LCL}{3\sigma}\end{cases} \quad (2)$$

Based on the value of Cp and Cpk, process can be:
- Cp < 1 – process should be redesigned
- Cp around 1,33 – process should be controlled
- Cp > 1,6 – process is non-critical

3.2. Control Charts

As already mentioned, control chart is one of the way of showing process capability. A control chart can be defined as a chart used to determine how the process changes over time. This chart consists of 3 lines, which represent the upper control limit, the mean value and the lower control limit (Pajić *et al.,* 2018). If a process that is being monitored by its value exceeds the control limits, then the process is considered statistically uncontrolled and needs to be improved.
When analyzing the processes, a wider tolerance zone was first used, where the lower and upper limits were determined on the basis of 3σ, after which the zone of tolerance with the limits determined on the basis of 2σ was used. When it comes to a wider zone of tolerance, all processes are within the limits, which implies control, but when observing narrower tolerance zone, the days with uncontrolled processes were observed. The obtained average values are shown on the control chart. On the basis of these values, the values of the upper, lower control limit as well as the mean value and standard deviation were determined. In determining the upper and lower control limit, the 2σ approach was used, for the above mentioned reason. This means that the value of the upper control limit was obtained as the sum of the mean value and standard deviation multiplied by 2. The lower control limit was obtained as the difference between the mean value and standard deviation multiplied by 2. Observing the control chart in order to determine an uncontrolled day, it was determined that this was on the 18th day when the delivery lasted longer than usual, which led to the appearance of an uncontrolled process (Figure 3)

Fig. 3.
Delivery times per days

Based on Figure 3 it can be seen that besides 18th day, the process was out of the control limits and on the 17th day, but it was not observed considering that it went over lower control limit, which means that this is even better result, i.e. shorter delivery time than lower control limit.

4. Results

In this paper, times of goods handover in the markets on the gas stations were analyzed. The data was collected from retailer who provides logistics activities to the markets at the stations and a total of 1783 handovers during 22 days were analyzed. In order to determine on which day(s) the uncontrolled process occurred, control charts were used. The values on the control chart were obtained as the average time of all realizations during that day. The number of realizations as well as duration of each varies depending on the day (Figure 4).

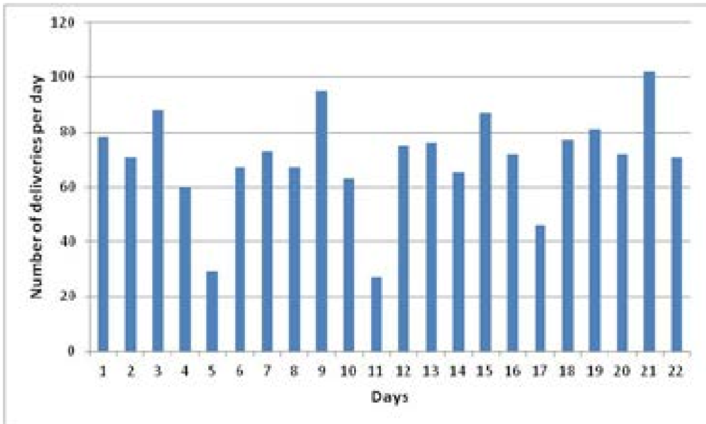

Fig. 4.
Number of deliveries per day

When comparing Figures 3 and 4, it can be seen that even though the 18th day is not the most affected day by the number of deliveries, it was still the day which was uncontrolled. In order to determine the capability of the process, Cp and Cpk indexes were calculated according to the formulas shown earlier in the paper. Based on these formulas, the following values were obtained: Cp=1.28 and Cpk=1.28, and based on these results, it was concluded that the process should be controlled (Kilibarda and Andrejić, 2014).

After defining the day that was statistically uncontrolled, the same was analyzed in detail. Given that there were 72 deliveries on that day, the total number of deliveries was divided into three charts, each containing 24 delivery times (Figure 5). And in this case the control limits are determined in the manner described earlier. However, in order to obtain the relevant value of the standard deviation used to calculate the control limits, the entire sample was taken into consideration and based on it the standard deviation was calculated and then applied to all three charts. In this way it was achieved that the value of the standard deviation is identical, since otherwise the value would be different in all three charts and obtained data would not be relevant.

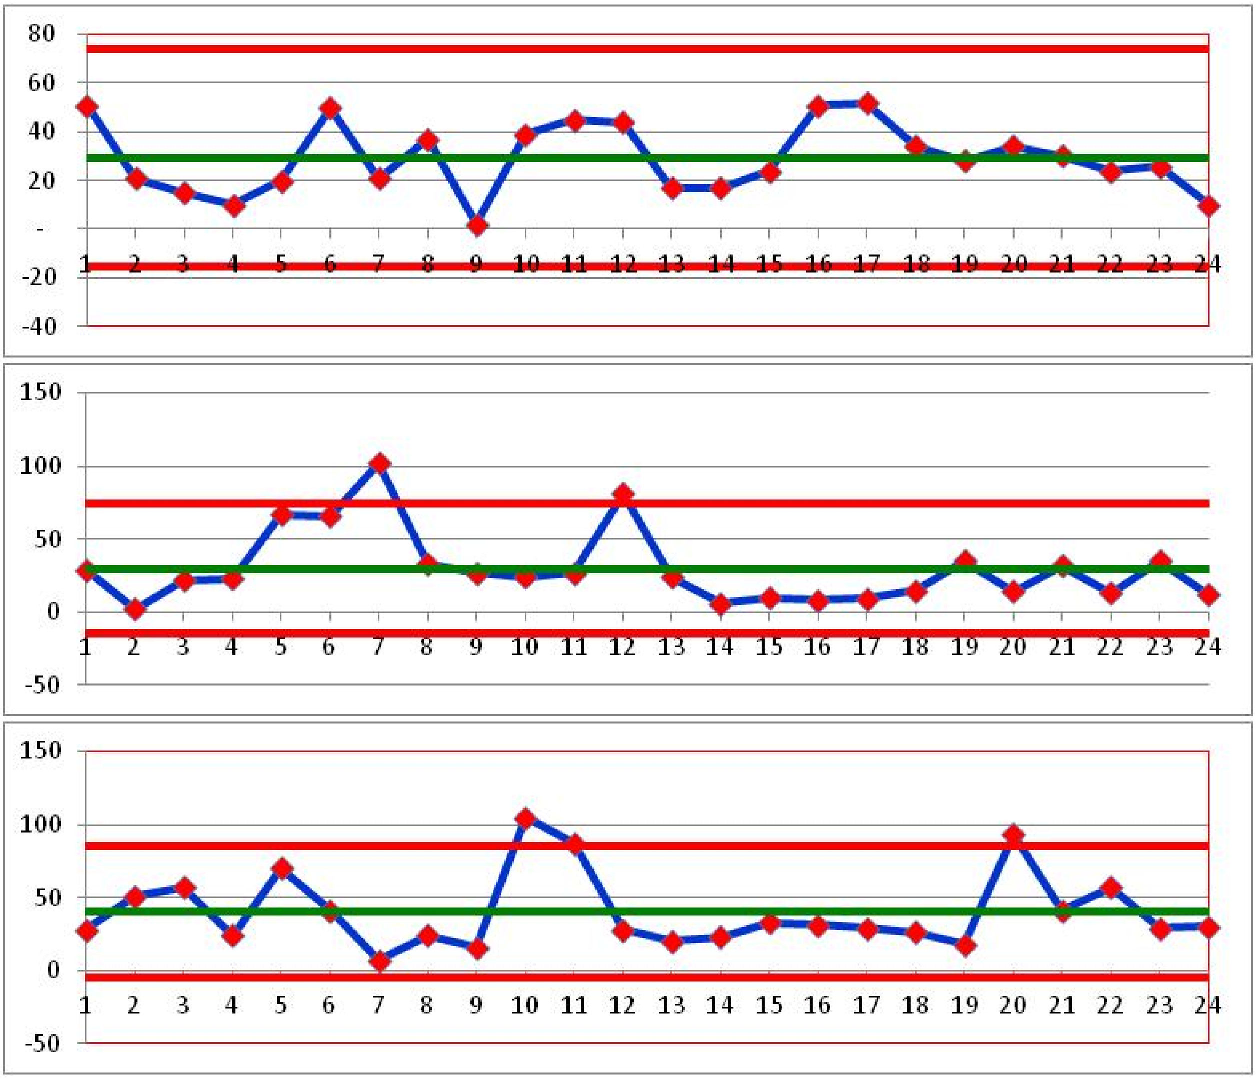

Fig. 5.
72 deliveries during the uncontrolled day

Of the total number of crossing over control limits on the displayed control charts, in two cases, crossing occurred in the morning hours (9:30 am and 10:09 am) while the remaining three occurred in the afternoon hours (13:51, 14:30 and 16:01 pm).

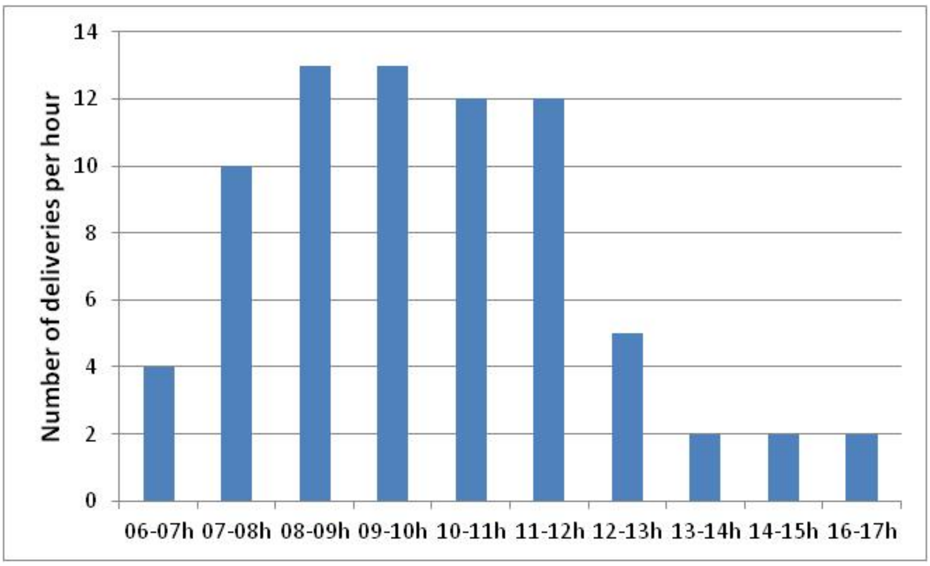

Fig. 6.
Number of deliveries per hour on the uncontrolled day

The reason for this may be the fact that there is a greater demand in the afternoon hours than in the morning hours, as confirmed by Figure 6 from which it can be seen that although there were much less deliveries in the afternoon hours than in the morning hours, the afternoon ones lasted longer. Also during the handover of goods, the presence of the employees of the gas station is necessary since the quantitative and qualitative control is carried out. Qualitative control refers to the shelf life of the product, while counting delivered products represent quantitative control which lasts longer. The reason for the long quantitative control is in fact that gas station stores require smaller quantities of products (often less than the unit of packaging). Another reason for the increased delivery time may be the crowd at the gas station itself, and as the presence of the workers during unloading is necessary, this may result in extended delivery time.

As a potential corrective measure in this case, the delivery time frame may be defined, in order to carry out delivery in periods of the day when the smallest crowd is at the station and when there are a greater number of workers who could receive the delivery. Also another solution can be night delivery in order to avoid crowds and thus speed up the delivery process. Reducing the duration of the quantitative and qualitative control could be achieved by using boxes that would be closed after picking and which could not be opened until the moment of the receipt of the goods, using a seal or a padlock. In this way, for any disagreement in quantity and/or quality retailer would be responsible, which would speed up the acceptance of goods at the gas stations thus shortening the delivery time.

5. Conclusion

Based on the analyzed case the importance of monitoring the time of certain logistics activities during the process of goods delivery can be seen. By reducing the time of realization of certain activities, many savings can be achieved, both in time and in costs. In order to determine the process control as well as the assessment of capabilities, control charts and statistical process control (SPC) were used. During the observed 22-day period, only one uncontrolled process occurred, which was then analyzed in greater detail. This more detailed analysis actually refers to the observation of that day to the hour level in order to determine in which moment during the day the uncontrolled process occurred, i.e. when the delivery lasted longer than usual. Only one day was uncontrolled, which speaks of the quality of the logistics service provided by the retailer. Finally, certain corrective and preventive measures that could be implemented to improve the delivery process are proposed.

Future research could be conducted in several different directions. The first direction relates to the research of new technologies (vehicles without drivers, drones, etc.) that would perform more frequent and less deliveries. The second direction refers to exploring the possibility of applying advanced information achievements and better linking of all participants of the supply chain. At the very end, there is a study of the human factor and the elimination of errors that arise as a consequence of the mentioned factor.

LOGISTICS CENTRES IN POLAND FROM THE PERSPECTIVE OF EUROPEAN STANDARDS – STATUS QUO AND DEVELOPMENT OPPORTUNITIES

Joanna Miklińska[1]
[1] *Gdynia Maritime University, Department of Logistics and Transportation Systems, Poland*

Abstract: For several decades, the Logistics Centres (LC) (also known as freight villages) have constituted an important element of the logistics systems in numerous countries. In Europe, there are over 240 facilities of this type. In each country, we can observe certain specificity of the Logistics Centres. It refers to the terminology and the applied organizational and legal solutions, as well as the number of premises. Despite some differences, the European LC have been developing based on a common set of criteria promoted by EUROPLATFORMS (related, *inter alia*, to the service offer, issue of intermodality and managing entity). Thanks to their attributes, the Logistics Centres satisfy the requirements of the sustainable development of transport. Many stakeholders in Poland have already shown interest in the Logistics Centres. At present, Poland is one of the most desirable logistics locations in Europe. However, we can observe here only several typical Logistics Centres where small share of modern warehouse space is located (today, in Poland, the resources of commercial space amount to more than 13 million square meters). Therefore, the aim of this paper is twofold 1) to present the current state of Logistics Centres development in Poland and analyse to what extent they meet the European standards 2) to identify determinants for the development of Polish Logistics Centres. In order to fulfil the main objectives of the paper a review of literature as well as analysis of statistical data, reports, documents published by the governmental agencies, real estate agencies and consultants have been conducted. In addition, comprehensive content analysis of websites, newsletters of Logistics Centres in Poland has been performed. The paper provides characteristics of the Logistics Centres existing in Poland, taking into account, *inter alia*, their structure, organizational and legal form and service offer. Factors affecting the development of LC in the Polish seaports and inland have been indicated. The paper also includes SWOT analysis of the Logistic Centres in Poland. The conclusions resulting from the analysis may constitute guidelines for other countries where Logistics Centres are planned and developed.

Keywords: logistics centres in Poland, freight villages, sustainable transport development.

1. Introduction

Logistics Centres are transport and logistics infrastructure facilities which have constituted important elements of macro-logistic systems of numerous European countries for several decades. In some of them (e.g. in Germany) LC were build in the second half of the 1990s. In Poland, the issue related to their development appeared in discussions of theoreticians and practitioners almost at the same time - at the end of the 1990s. At that time, the first significant planning works began. In 2000, the analysis results were published indicating the location for six Logistics Centres in the country (situated at the intersection of the existing and planned infrastructure of various modes of transport) (Krzyżanowski, 2000, 17). It must be mentioned that Poland at that time was at the beginning of economic transformation and development of market economy. The lack of modern warehouses in the country and the development of TSL market and trade represented opportunity for LC development, generated demand for such facilities. At the same time, due to years of negligence, in the country there were almost no highways, there was a shortage of railway lines of proper standard and intermodal terminals. The ownership issue of numerous plots of land was also problematic. In the country, the bodies of local government were only brought into being and there was a shortage of good practices and rules regarding Public-Private Partnership. Till today, only a few Logistics Centres have been established in Poland, and they meet the European standards to various degree. The present stage of LC development in Poland has been affected by numerous factors of different nature. In time, new determinants have occurred and will provide the direction for LC development in Poland. They will be specified further in the article.
The aim of this paper is: to present the current state of Logistics Centres development in Poland, analyse to what extent they meet the European standards and to identify determinants for the development of Polish Logistics Centres. The author has already conducted research on the concept of Logistics Centres (Miklińska, 2008), selected problems related to LC (Miklińska, 2015a), and the development of LC in the Polish seaports (Miklińska, 2015b). Today, after several years and subsequent changes which provided new requirements, it was decided to extend research and perform analysis of the current state of LC in Poland. In order to fulfil the main objectives of the paper, a review of literature as well as analysis of statistical data, reports, and documents published by the governmental agencies, real estate agencies and consultants have been conducted. In addition, comprehensive content analysis of websites, newsletters of Logistics Centres in Poland has been performed. The paper also includes SWOT analysis of the Logistics Centres in Poland.

2. European Standards and Attributes of Logistics Centres - Literature Review

In particular European countries, to define logistics facilities which constitute the subject of analysis in this paper, the following concepts are used, e.g.: freight villages, Güterverkehrszentren, Interporti. Despite terminological differences, in the development of European LC we can indicate some common features. They include a set of general criteria – attributes. They have been included in the most popular, in reference literature, definition of Logistics Centre concept

[1] Corresponding author: j.miklinska@wpit.am.gdynia.pl

(earlier - freight village) provided by EUROPLATFORMS: „A Logistics Center is a center in a defined area within which all activities relating to transport, logistics and the distribution of goods – both for national and international transit, are carried out by various operators on a commercial basis. The operators can either be owners or tenants of buildings and facilities (warehouses, distribution centres, storage areas, offices, truck services, etc.), which have been built here. In order to comply with free competition rules, a Logistics Center must be open to allow access to all companies involved in the activities set out above. A Logistics Center must also be equipped with all facilities to carry out the mentioned operations. If possible, it should include public services for the staff and equipment for the users. In order to encourage intermodal transport for the handling of goods, a Logistics Center should preferably be served by a multiplicity of transport modes (road, rail, sea, inland waterway, air). To ensure synergy and commercial cooperation, it is important that a Logistics Center is managed in a single and neutral legal body (preferably by a Public-Private-Partnership). Finally, a Logistics Center must comply with European standards and quality performance to provide the framework for commercial and sustainable transport solutions" (EUROPLTFORMS EEIG).

Under this definition, as well as other studies of the said organization (EUROPLATFORMS EEIG, 2015, 4), the main features of LC have been distinguished: multi-stakeholder approach, defined principles regarding LC property (usually, ownership or lease), open access, multimodality, modern LC facilities, management body (preferably PPP), cooperation of entities within LC, achieving synergy effects, compliance with sustainable transport requirements. The requirements LC should meet have been analysed further in reference literature. Recently, numerous publications have been dedicated to the issues of green solutions in LC – the issue of greening LC (Altunaş&Tuna, 2013, 59-80) and their sustainable development (Baydar, Süral, Çelik, 2017, 1214). The issue of Logistics Centres location and methods to determine them has been analysed as the idea of fundamental importance for the success of LC (Kayikci, 2010, 6297; Özceylan et. al., 2015, 38). Moreover, reference literature provides numerous mentions on synergy effects achieved, e.g. in German LC (Winkler&Seebacher, 2012, 399-410), significant attention is also devoted to the structure of entities managing these LC (Nestler&Nobel, 2009, 332-333). Furthermore, already in the 1990s, city-logistics projects completed with the participation of LC constituted a significant area of interest in Germany; it was the hallmark of those centres (ISL&LUB Consulting GmbH, 2010, 4). Over the years, under the changes in environment the Logistics Centres have been facing new requirements. Today, the challenges ahead of them include: digitalization, e-mobility and introduction of autonomous vehicles (DGG, 2018).

The previously specified attributes constitute a very general set of criteria. In the case of each country detailed solutions are determined by the existing economic and legal conditions or technical and technological ones, e.g. conditions within transport infrastructure. It is difficult to enumerate unambiguous requirements and technical standards LC should meet. Under the document developed by EUROPLATFORMS we can indicate particular regularities in the development of LC in Europe. In 28 EU countries there are ca. 240 LC, and countries with the largest number of them include: Germany (35 LC), Spain (33 LC), France (26 LC) and Italy (21 LC) (EUROPLATFORMS EEIG, 2015, 16). The average area of the European LC amounts to 108 ha; however, their size in particular countries is very diversified and fluctuate from several to even several hundred hectares (EUROPLATFORMS EEIG, 2015, 16). We need to mention that LC from Italy, Germany and Spain rank among the top ten in the European LC from 2015 (ISL&DGG 2015, 5). It is worth focusing on Germany – a country which ranks first in Europe regarding the number of LC. In this country the total area of LC amounts to 6,132 ha, which generates the average size of LC - ca. 175.2 ha (EUROPLATFORMS EEIG, 2015, 16). The German LC are also characterised by multi-stakeholder approach since already in 2010, in all facilities there were ca. 1,300 enterprises (there are on average 37 enterprises per one LC) (ISL&LUB Consulting GmbH, 2010, 4). From the perspective of meeting the principles of sustainable development it is important that all German LC have direct access to the infrastructure of at least two transport modes, and 20 of them are trimodal LC. Furthermore, in almost all LC or in their vicinity intermodal terminal is located. In this respect, data of all European LC is not so optimistic. The majority of LC meet the requirement of multimodality, 100 LC have direct access to two modes of transport, 105 LC – to three and 15 to four transport modes. We also need to indicate that 20 LC from among the 240 specified in Europe have direct access to the infrastructure of only one transport mode. The location of the majority of European LC complies with the location of key nodes of the Trans European Transport Network (EUROPLATFORMS EEIG, 2015, 18-50).

3. Requirements and Determinants for the Development of Logistics Centres in Poland

From the initial plans till today, only several typical Logistics Centres have been established in Poland (they are characterised in Table 1). Their development has been affected by numerous factors, mainly economic and geopolitical ones related to international trade, development of the national transport system, including mainly the development of linear and nodal transport and logistics infrastructure. Significant factors have been indicated below.

As mentioned before, the construction of LC was planned in Poland only several years after the beginning of political and economic transformation and development of market economy. Economic relations changed and new trade partners became important. Before the transformations of 1980, the main trade partners of Poland included: Soviet Union, Federal Republic of Germany, East Germany and Czechoslovakia. Already after the transformations significant change was observed; at that time, the countries with the largest share in trade with Poland included (in 2000) Germany, Russia, Italy and France, and recently (2016) they include, in the import of goods: Germany, China and Russia, and in export: Germany, Great Britain and Czech Republic (Central Statistical Office, 2008 and 2017). Such fact affected the change in the directions of cargo transport and the new requirements regarding the location of nodal infrastructure facilities. In Poland, as in other European countries, the change was affected by the development of globalization and offshoring – moving the production to Far-East markets. Today, e.g. thanks to geographical location, Poland, by means of trade with China, as well as location on the cargo transit route constitutes an important European point on the map of New Silk Route - One Belt One Road (OBOR) Initiative. The fact provides opportunity for intense cargo handling and may generate the need to establish another modern LC in the future. While discussing global cargo transport we need to indicate that today over 80% (by volume) and over 70% (by value) of global trade cargo is carried by sea; the volume of containerized cargo transport has still been increasing (UNCTAD, 2017, 1-12), which generates requirements also for the Polish seaports and LC located in these ports.

Taking account of infrastructural requirements, we need to indicate that in recent years the situation in transport infrastructure in the country has been improving. In the case of road transport – in 2000 in the country there were 250 000 km of hard surfaced roads, in 2005 - 254 000 km and in 2015 already 420 000 km. Moreover, we need to indicate that in 2000 there were only 358 km of highways, in 2005 - 552 km, and in 2015 – 1 559 km. In the case of railway infrastructure the situation regarding the length of tracks deteriorated since in 2000 there were 22 560 km of tracks in operation, in 2007 – 20 107 km, and in 2016 – 19 132 km (Central Statistical Office, 2008 and 2017). We need to emphasize that since 2000 nearly 3 500 km of tracks were taken out of operation, due to lack of financial resources for their modernization. However, at the same time numerous main rail roads were modernized, which contributed to improving the situation on important transport routes. In relation to the opportunities for LC development, in particular trimodal ones, we also need to pay attention to inland waterway transport. In Poland, this mode of transport is characterized by extremely low share in the total volume of transport and amounts only to ca. 0.3% related to the weight of transported cargo. The situation results, *inter alia*, from infrastructural negligence. Over the last several decades, the length of waterway recognized as navigable has decreased - in 2000 there were 3 813 km and in 2015 – 3 655 km (Central Statistical Office, 2008 and 2017). Unfortunately, the majority of inland ports are also in poor technical condition. One of few exceptions can be found in Gliwice port, located at the Oder River, which constitutes part of Silesian Logistics Centre (Table 1); similar situation can be observed in Szczecin.

In recent years, various stakeholders take actions supporting the development of intermodal transport in Poland. From 2008, the volume of railway intermodal transport increased from 4.8 million tons to 14.7 million tons in 2017; moreover, more and more railway carriers decide to handle such transport (in 2017 there were already 18 of them) (UTK, 2018, 2). However, the share of intermodal transport (measured by transport performance) in the railway sector amounts only to 8.8% (in 2016); to compare - in Germany in 2015 it is 37.9% and in Switzerland 50.7% (UTK, 2017, 6). Therefore, there is still significant potential for development.

Today, in Poland there are over 30 intermodal terminals. The experience of many European countries proves that close vicinity of terminals inland as well as those located in seaports constitute one of the main factors affecting the LC location. Therefore, attention should also be paid to the development of sea container terminals in Poland. Over the last several years, some new facilities of such type have been established and their role has strengthened, and even the world largest sea-going container vessels call at one of them, namely Deepwater Container Terminal (DCT) in Gdańsk. Recently, we can observe significant increase in the volume of containerised cargo handling in the Polish seaports. In 2000, 448 655 TEU was handled in total, in 2012 already 1 656 927 TEU, and at the end of 2017 - 2 384 785 TEU (at the above mentioned DCT 1 580 508 TEU) (Matczak&Ołdakowski, 2010; Rozmarynowska-Mrozek&Ziajka, 2018, 4). At each of the three largest Polish seaports there is a Logistics Centre, although each developed as per slightly different model (Tab.2). Unfortunately, too few LC are established in seaport hinterland area, connected with intermodal terminals already located in that area, to play the role of dry ports, e.g. as per German model (Olah&Nestler&Nobel&Popp, 2017, 2). In conclusion, over the past years the situation regarding the development of transport infrastructure in Poland has improved. For several years, significant efforts regarding the construction of new infrastructure and modernization of the existing one focus on facilities located along two core network corridors TEN-T in Poland: Baltic-Adriatic and North Sea-Baltic.

One of the main factors affecting the current position of LC in Poland involves the development of modern warehouse space market. Warehouse facilities constitute basic elements of the European LC. Unfortunately, in Poland modern warehouses are predominantly located outside the typical Logistics Centres. It results from the fact that during the construction of warehouses the Logistics Centres in Poland failed to provide such opportunity due to their low number. Therefore, the question arose why typical LC in Poland were not established although it was known there were needed and there were plans for their locations. The factors which caused such situation were numerous, e.g.: lack of financial resources, issues with the development of linear transport infrastructure (leading to LC), ownership issues regarding land and transfer of ownership, lack of optimal regulatory solutions and good practices regarding PPP (the first act enacted as late as in 2005, and another in 2008). Therefore, what was the history of the development of modern warehouse space market? We need to indicate that still in 1996 in Poland there were virtually no modern warehouses. Over several years, the situation changed significantly. It happened thanks to a number of factors generating demand for modern warehouses, *inter alia*: development of chain stores in Poland, development of logistics services market and in recent years the development of e-commerce market, with rather low labour costs and costs of warehouse construction. As a result of those and other determinants, at the end of 2017 market resources reached ca. 13.5 million m^2. On the Polish market, there are warehouses of the largest global and European developers (e.g. Prologis, Panattoni, Segro, Logicor and Goodman) (JLL, 2018). As mentioned before, in the years of dynamic development of the modern warehouse space market, there was (and still is) a shortage of Logistics Centres and developers located their warehouses in places of their choice. Therefore, a significant number of modern warehouse space in Poland fails to meet the

requirement of multimodality – most of warehouses have access only to road transport infrastructure and fails to have direct access to intermodal terminals. From the perspective of sustainable development of transport it is very unfavourable. We also need to indicate that locating warehouses outside typical LC makes it impossible to include them into IT systems, connecting various users, e.g. similar to Port Community System (Marek, 2017, 457). It also limits the possibility to achieve synergy effect, which is possible in typical LC thanks to the cooperation between enterprises.
However, we need to look to the future. Today, Poland is one of the most wanted logistics location in Europe (Prologis, 2017,1); significant increase in warehouse space is predicted. Together with the construction and development of another LC it would be possible to locate the newly built warehouses within the structure of LC. There is no doubt that the development of warehouse space market and potentially also LC will be affected by new determinants, at least the ones resulting from the need to build warehouses for e-commerce customers, where warehouses must be located closer to final clients as well as more and more important warehouse automation.

4. Characteristics of Logistics Centres in Poland

As indicated above, the criteria for distinguishing logistics centres from among other logistics facilities are not precise. Consequently, the nature of existing facilities is disputable and, therefore, in some countries it is difficult to indicate the actual number of LC. In Poland, there are several areas and facilities (e.g. in Mszczonów and Żurawica-Medyka) that develop into typical LC. While discussing the stage of development of Logistics Centres in Poland, the author provided characteristics of facilities specified as LC in the publication of EUROPLATFORMS, 2015, which include: Pomeranian Logistics Centre, Logistics Centre in Port of Gdynia, Logistics Centre in Port of Szczecin, Silesian Logistics Centre, Multimodal Logistics Centre CLIP Group, Euroterminal Sławków. Moreover, one additional facility was analysed - Wielkopolska Logistics Centre, which, according to the author, features important attributes, making it possible to recognize the facility as Logistics Centre (and is recognized as such in literature -Lipińska-Słota, 2008- and in practice). The analysis was conducted mainly under information provided by Logistics Centres (on their websites and in publications). Due to limited length of this study, the author selected and presented several main groups of LC features (Table 1), crucial from the perspective of European LC concept. They include attributes which enable presenting the stage of development of particular LC in Poland and their comparison.

Table 1
General Information on Logistics Centres located in Poland

Logistics Center	**Location / surface**	**Transport modes / intermodal terminal**	**Management body/ management function**	**Entities operating within LC, their specialty / type of LC services**	**Additional information**
Pomeranian Logistics Centre	in the northern part of the country, by the Baltic Sea, in the vicinity of the Port of Gdańsk and Deepwater Container Terminal (DCT); 9 km from the centre of Gdańsk; the total area of LC ca. 187 ha in area, on area of 110 ha Goodman developer will build warehouses of 500. 000 m^2	road/rail/sea - direct access to DCT, near A1 highway, S6 and S7 express roads, near intermodal terminal at DCT and railway infrastructure	Gdańsk Economic Development Agency (InvestGDA) (100% City of Gdańsk) – total area of LC; warehouse facilities managed by Goodman developer	dominant are warehouse leaseholders in LC from logistics sector; high-tech industry, petrochemical, cosmetic industry	near Tricity – ca. 1 million inhabitants – large market
Logistics Centre in Port of Gdynia	in the northern part of the country, in Gdynia, by the Baltic Sea, in the Port of Gdynia; LC covers the area of ca. 30 ha incl. ca. 20 ha for planned manoeuvre and storage yards;	road/rail/sea - direct access to Baltic Container Terminal (BCT) and Gdynia Container Terminal (GCT) (Port of Gdynia), 40 km to A1 highway, 6 km to S6 expressways, near intermodal terminal at BCT, access to railway infrastructure	Port of Gdynia Authority S.A. (PGA S.A) (shareholders: State Treasury about 99%, Municipality of Gdynia 0.2%, other shareholders)	warehouses (developer - PGA S.A) leased by: Logistics Service Providers, customs agencies and other entities, in LC also industrial properties of other enterprises from various sectors	new intermodal terminal planned within LC
Logistics Centre in Port of Szczecin	in the northwest part of the country, by the Baltic Sea, within the Port of Szczecin near DB Port Szczecin Container Terminal; LC 20 ha in area – internal infrastructure built by port authority; new operator – developer from Waimea Holding group will build warehouses of total area of 45 000 m^2	road/rail/ inland waterway- 8 km to A6 highway and E-65 road – access to railway infrastructure C-E59 and E-59	Waimea Logistic Park – Szczecin Seaport - developer under agreement will manage warehouse facilities	within LC there are several entities from various sectors, additionally bonded warehouse will provide services, Duty Free Zone, logistics services and light manufacturing	recently warehouse market of this region is developing dynamically
Silesian Logistics Centre JSC (SLC JSC)	in south of Poland, in Gliwice - the largest and most universal inland waterway port in Poland; at the beginning of Oder River Waterway; SLC area is divided into two parts 47 ha in Gliwice and 12.58 ha in	road/rail/inland waterway - close to intersection of A1 and A4 highways, access to railway infrastructure, station Gliwice Port and inland waterway Gliwice Port;	Silesian Logistics Centre JSC - Shareholders: Gliwice City (77.78%), DB Cargo Polska S.A. (20.55%),	SLC JSC provides services for: dangerous goods, mineral fertilizers, industrial, neutral and paper goods, food products and	LC located attractive for OBOR Initiative; the new class A warehouse is bimodal –

Logistics Center	Location / surface	Transport modes / intermodal terminal	Management body/ management function	Entities operating within LC, their specialty / type of LC services	Additional information
	Gliwice Sośnica, 59.58 ha in total; total storing area in five class A warehouses equals 28 000 m2	intermodal terminal (area of 5 hectares and capacity of 2.900 TEUs) managed by PCC Intermodal	OT Logistic S.A. (1.32%), other (0.34%)	containerized cargoes; Duty Free Zone and Customs Agency	available for road and rail transport;
Multimodal Logistics Centre CLIP Group	in the central part of the country, near Poznań, at intersection of two TEN-T corridors, North Sea – Baltic and Baltic – Adriatic; LC warehouse facilities include six warehouses A class of total area of 300.000 m^2, another under construction	road/rail- LC located close to S5 expressway and A2 Berlin–Warszawa highway, at E20 railway; near intermodal terminal – total area of terminal 10 ha and storage area 4500 TEU, equipped with dedicated IT system	logistics centre is part of Clip Group	Clip Group offers: logistics and storage services; bonded warehouse services; road and railway transport services; services for containerized cargo; Operator - STS Logistic-services for automotive industry	Member of EURO-PLATFORMS; 15th place in the ranking of European LC; regular transport to/from China within OBOR Initiative
Euroterminal Sławków	in the south of the country, on the outskirts of Silesia Agglomeration; the main part of logistics facility is intermodal terminal of 90.28 ha in area; from 2008 high storage warehouses of 8 000 m^2 were built	rail/road- -direct access to Broad-Gauge Line LHS (1520 mm) of ca. 400 km towards East; connection with CE30 and CE65 lines, road connections: to highways: A1 - 8 km, A4 -10 km, to E40 road - 5 km, intermodal terminal – handling capacity, 284 000 TEU/year	Euroterminal Sławków Sp. z o.o.- shareholders: CZH S.A., PKP Cargo S.A. and PKP LHS Sp. z o.o.	handling of containers, semitrailers and other types of cargo (loose, liquid); services: forwarding and storage (bimodal warehouse); comprehensive customs services – Customs Agency	in 2008 Euroterminal Sławków began the construction of International Logistics Centre
Wielko-polska Logistics Centre	in the central part of the country, LC has the area of 100 ha separated for business activity	road - (unimodal LC); close to intersection of A2 highway and road no 25; railway terminal at E20 railway line in preparation	Wielkopolska Logistics Centre Konin – Stare Miasto S.A.; stakeholders: City of Konin, Stare Miasto municipality and 13 private companies	within LC there are industrial facilities for companies of various sectors; LSP provides forwarding services (road and sea), warehouse and customs services; construction of custom-made warehouses, lease of class A warehouses	one of the first LC in Poland (2001)

Source: own elaboration of the author based on: Port Gdańsk. 2018. http://www.portgdansk.pl; Clip Group. 2018. http://clip-group.com; Gdansk Economic Development Agency. 2018. http://investgda.pl/pcl; Port of Gdynia Authority S.A. 2018. https://www.port.gdynia.pl; Silesian Logistics Centre JSC. 2018. https://scl.com.pl; Wielkopolskie Centrum Logistyczne Konin-Stare Miasto S.A. 2018. http://www.wcl.pl; Port Szczecin-Świnoujście. 2018. http://www.port.szczecin.pl; „Euroterminal Sławków" Sp. z o.o. 2018. http://www.euterminal.pl; Terminals Catalogue 2018; Goodman, Warehouse Space…; ISL, DGG 2015, Positioning and Establishment….

Due to limited length of this study it is difficult to analyse in detail the specificity of each LC indicated in Table 1. With reference to the European standards, we need to indicate that in terms of the number of LC in the country, taking account of the area of Poland, their number is lower than the number of LC in countries of similar area. Whereas, referring to the volume of LC we can indicate that particular LC in Poland, in terms of volume, does not differ from the standards observed in other countries. The largest LC in Poland covers ca. 180 ha and the smallest, several hectares. Taking account of the principles of sustainable development, we need to indicate that apart from one facility, all Polish LC are serviced by at least two modes of transport and two are trimodal. Almost all LC in Poland have access to intermodal terminal. In the facility which fails to provide such solutions, the terminal is already planned.

The service offer of Polish LC is very diversified. In each of them there are mainly handling and storage services as well as a wide offer of forwarding and logistics services. We can also observe certain specialization of services in some LC, for example these located in seaports, near container terminal. They handle containerized cargo carried in international transport. The services rendered by LC in Poland result from the activities of enterprises who run their business activity in LC and, as it is in many cases, rent warehouse space in LC. In some cases, services are rendered by the LC main operator and its leading entity.

With regard to the issues of entities managing the Polish LC, it is difficult to indicate only one model. In some cases, this is the operator as well as the owner and manager of warehouse facilities. At the same time, we need to remember that in some cases, the entity has a complex structure of shareholders including, *inter alia*, railway carriers, city and private entities (e.g. Silesian Logistics Centre) or city, municipality and private entities (e.g. Wielkopolska Logistics Centre). Thanks to such solutions in some cases we can conclude that Polish LC take the form of PPP.

In publications on the activities of Polish LC it is difficult to find any information on cooperation projects between enterprises in LC, on typical City Logistics projects with the participation of LC, or on many green solutions in LC (on the Polish market of logistics services such solutions are already in place – Klopott&Miklińska, 2017). In other countries, e.g. German LC, we can find numerous examples. One of the reasons for such situation in Poland, apart from those related to particular enterprises, may include lack of organization of national character connecting Polish LC and defining significant cooperation projects supporting innovation programs, following the German model of DGG. There is no doubt that such organization should be established.

3. SWOT Analysis of the Logistics Centres in Poland and Conclusion

The previous analyses on factors affecting the actual and future stage of LC development in Poland lead to conclusion providing that they involve areas of different nature. The following, simple SWOT Analysis for Logistics Centres in Poland, instead of conclusion, indicates strong and weak points of LC in Poland and opportunities and threats for their development.

Table 2
SWOT – Analysis of the Logistics Centres in Poland

Strengths	**Weaknesses**
- favourable location of existing LC relative to infrastructure of basic modes of transport and TEN-T, - location of LC in places of high demand for their services, - good condition of transport infrastructure leading to LC, - multimodal character of LC and access to intermodal terminals of almost all LC, - developing service offer of LC, - PPP-related solutions in LC.	- too small number of LC in the country, - uneven spatial distribution of LC in the country, - numerous modern warehouses in the country outside LC, - lack of cooperation projects in LC and poor awareness of their advantages, - lack of significant number of green solutions in LC.
Opportunities	**Threats**
- central location of Poland in Europe and high demand for modern warehouses in Poland, - improved transport infrastructure in Poland and its development within TEN-T corridors, - development of intermodal transport, - increase in the number of PPP projects in the country, numerous good practices of PPP, - development of sea container terminals in Poland, - development of cargo transport within OBOR Initiative.	- construction of new warehouses outside typical LC, - increase in attractiveness of warehouse markets of neighbouring countries, - lack of sufficient interest among enterprises to locate their activities in LC, - lack of current plans for LC development in Poland, - lack of dedicated organization supporting the development of LC in Poland, - changes in economic conditions and trade relations.

Source: own elaboration of the author

The history of Logistics Centres development in Poland was not easy. It involved difficulties common in many countries that went through political and economic transformations and where market economy was established much later than in many neighbouring European countries. Due to negligence in infrastructure, lack of financial resources and first of all unstable formal and legal conditions, today there are only few typical logistics centres in the country. Other countries, in terms of area only slightly larger than Poland have over twenty or thirty LC. Due to unfavourable conditions, in the period of dynamic development of the modern warehouse space market there was a shortage of LC in Poland, where such warehouses could have been located. It is predicated that the resources of the Polish warehouse market will double in the nearest future; therefore, there are opportunities to build some of them in LC and construct another facilities of such type in Poland. We need to emphasize that in 2015 one of the Polish LC – CLIP Group in Poznań succeeded and was ranked 15th among the European LC (ISL&DGG 2015, 5); it is also a member of EUROPLATFORMS. Such good examples regarding Polish LC give hope for their further successful development.

PROBLEMS REGARDING INTERMODAL TRANSPORT IN THE DANUBE REGION

Snežana Tadić[1], Slobodan Zečević[2], Danijela Milenković[3]
[1,2,3] University of Belgrade, Faculty of Transport and Traffic Engineering, Belgrade, Serbia

Abstract: With the efficient use of intermodal transport for solving the issue of sustainable development and environmental protection, one of the main goals of the international community has been realized, and therefore, it is an important factor in the economy functioning. Apart from these areas, the problems of intermodal transport also reflect on the problems of functioning and connecting globally and locally, and it is important to study, treat and solve them. By reviewing and analyzing national strategic documents, the key problems of intermodal transport in the Danube Region were identified. The areas that needed greater attention were identified, the biggest problems of a different nature (financial and non-financial) were highlighted, as well as those that were not recognized. By analyzing the identified problems, the space for more effective and efficient definition of priorities and measures for solving the shortcomings in the system is opened for the purpose of overall economic development.

Keywords: intermodal transport, problems, Danube Region, national strategic documents.

1. Introduction

National strategic documents are different plans created with the aim of development a certain area within a specific period. They contain defined goals and measures for their realization. For improving the area, it is necessary to identify the problems and link them to the purposeful and targeted actions in order to solve them. This paper presents an analysis of strategic documents that directly or indirectly refer to transport, i.e. intermodal transport (IT) in the Danube Region (DR) countries. The aim of the analysis is to identify the key problems described in the plans - the existing shortage requiring intervention.

The identification of critical areas (the greatest number of problems, the biggest obstacles to the functioning of the system) helps decision-makers to define the proper measures, actions, and direct them to solving the problem. The slightest progress in the area that boosts the problem will be significant. In addition to providing an overview of IT issues, this paper focuses on areas that require greater attention, and are often common to many countries. At the same time, it identifies issues that are not included in the plan, and exist in everyday business. Separating the problem is necessary given the constraints of the different resources and the effectiveness of the proposed actions.

The main goal of IT is applying different modes of transport in order to reduce overall costs and improve the quality of services. Savings in energy, costs and time, less environmental pollution, and other positive effects of IT applications gain increasing attention in developed European countries (Caris et al., 2013). The goals of a competitive and efficient European transport system (EC, 2011) can only be achieved by more intensive development of IT (Zečević et al., 2017). Solving IT problems increases its efficiency and enables its higher market share, and thus the growth of the economy in general. The unit increase in the share of intermodal transport gives rise to the third degree of the unit value of GDP/capita (FTTE, 2018).

The Danube region encompasses 14 countries (EC, 2010), which are mutually different from the aspect of socio-economic indicators, representation and quality of IT, volume of flows and its treatment. Based on these characteristics, in order to analyze the situation in different parts of the Danube region, the countries have been grouped into functional micro-regions (FTTE, 2018).

2. The Biggest Obstacles to Intermodal Transport

In the analysis of the national strategic documents in DR countries, the 43 problems have been identified. Their representation in different countries differs and is the greatest in the strategic documents of Croatia (MoSTI, 2014), Serbia (MoCTI, 2008, MoCTI, 2015), Ukraine (Dornier at all, 2016) and Moldova (GovMD, 2013), while it is the least in the documents of Austria (Lakatos et al., 2015; BMNT, 2002; MBVIT, 2011a; BMVIT, 2011b) and Germany (BMVI, 2010).

The biggest obstacles to IT development are the problems that directly affect the potential user. They relate to subsystems, elements of the IT system (intermodal units, transport means, transport infrastructure, terminals and terminal networks, operators, service providers, organizations, telematics), regulation and institutional framework. The problems that have the strongest impact on the development of IT make 41.72% of the identified ones, and are shown in Table 1.

Table 1
The most important problems of IT in strategic documents of Danube Region countries

Problem	Participation in	The number of

[1] Corresponding author: s.tadic@sf.bg.ac.rs

	all identified problems (%)	countries in which it was recognized
Lack of information and communication technologies (ICT)	5.69	12
Railways	4.74	10
Lack of (appropriate) terminals	4.27	9
Obsolescence and lack of vehicles	3.79	8
Time of travel	3.32	7
Unregulated law in the field of intermodal transport	2.84	6
Outdated technology in terminals	2.84	6
Customs formalities and offices	2.37	5
Permitted axle pressure (min. 22.5 tones/axle)	2.37	5
Connection of other hubs	2.37	5
Institutional framework	1.90	4
Sailing conditions	1.90	4
Delays at border crossings	1.90	4
Connection of city terminals/hubs	1.42	3

The outdated vehicles, especially those in rails and in water transport, are common problem faced even by the developed countries. These assets are more expensive than road ones, which compensate for their longer lifespan and permeability. It is not a rare situation that there cannot be found the required number of R rail truck, intended for the transport of intermodal units, in the European network. In addition to transport vehicles, the lack of intermodal transport units (ITUs) was also observed. Besides, there is a significantly smaller number of ITUs owned by a service provider (they are mostly owned by a sender/recipient of goods). In this field there is a considerable space for saving and improving efficiency.

Constraints at border crossings can be conditioned by the duration of customs formalities, but also by traffic density and volume. Customs formalities can be complicated (require additional documentation, etc.), but using the advanced information systems, implemented in a short period. The procedures and organization of the intermodal transport chain, especially in the system involving the railways, can have a greater share in the time structure of the chain (up to 60%), starting from the period of performing transport.

Problems at border crossings, congestion and waiting (according to the measurements in Serbia, in road traffic up to 4h (Republic of Serbia, 2017)) and complicated procedures (railway bill of loading (CIM) demand more attention and information than a bill of loading in the road transport (CMR)) and significantly obstruct the functioning of IT. According to the European Agreement on Important International Combined Transport Lines and Related Installations, AGTC (UN, 2010), retaining on the borders for compositions from ITU should not be longer than 30 minutes, the procedure should be simplified and should enable fair competition between rail and road transport.

The problem of legislation relates to the unregulated business and working conditions of operators in IT. In some countries, stimulating measures for this branch of economy are clearly stipulated (BMVIT, 2018), as well as are restrictions and permitted concessions to operators. The undeveloped IT in DR is also confirmed by the fact that hardly any strategic document treats this area as a separate entity. Ministries dealing with transport issues, mainly IT area, in an organizational sense, add it to the railways. This is also an issue of the institutional framework.

The institutional framework implies different authorities, societies, coordination agencies and national and international issues in the field. They can play an important role on the international scene; they can provide significant support to operators on the international scene, but also lead, improve the business conditions and perform promotional and other activities, everything in the favor of IT development. Such authorities or societies may be the first point of contact to a foreign company which wants to deal with the provision of IT services or claims this service in another country. Also, vice versa. The least such an institution can do is to provide useful information and guidance that will lead to the development and greater representation of IT with its promotion. The lack of institutions is mostly reflected in the low representation of IT technologies in the transport market, lack of awareness of its abilities, ignorance of the system, but also the lack of an adequate supply of services.

3. Critical Areas and Nature of the Problem

All identified problems of DR countries (43 problems) have been grouped in 16 areas, according to the type and character. Their number (in all DR countries) is shown in the table 2. Regardless the area of belonging, the problems can be divided into financial and non-financial. Solving problems of a financial nature requires significant investments (for example, the development of a transport infrastructure or intermodal terminals). Unlike them, the problems of a non-financial nature can be solved with much less money invested.

Table 2
Number of problems per area

Area	Number of problems (all countries)
Business	45
Transport infrastructure	36
ICT	22
Finance	20
Ecology	14
Projects	13
Terminal	11
Border crossings	9
Terminal network	9
Vehicles	8
Workforce	6
Law	6
Institutions	4
International cooperation	3
Politics	3
Flows of goods	2
Total	**211**

Over one fifth of all identified IT problems in DR is related to business problems. These problems are non-financial ones in their nature, and account for 48% of all financial problems. Typical representatives of the business problem are the unbalanced market, bad practice in companies, poor resource utilization and non-transparent business, primarily of the national railway operator. Apart from business problems, the significant problem of non-financial nature is the lack of plans for development/investment in intermodal transport (3.32% of the total identified problems).
The bad practice of companies, as the biggest problem, in addition to the non-liberalized market, refers to the following: irrational use of resources and their allocation; lack of cooperation between companies; inefficient choice of supply and placement of products; railway operators who do not endeavor in a competitive fight (where, regardless relatively good transit time, much is lost in initial/final operations), and also other companies that do not run their business efficiently, effectively and ecologically (EEE, Efficiently Effectively Ecologically). An irrational and inefficient business includes the insufficient use of available resources, mainly in the area of railway circuits and resources in terminals. This problem was observed separately from bad business since the latter can be in the scope of the first one, but not necessarily. The non-financial problem, identified in eight DR countries, is also the non-liberalized market. This refers primarily to services in rail transport, where the primacy is usually given to a national carrier holding the monopoly. Besides, problems of the non-liberalized market also relate to unequal conditions of access to the services of some logistics centers, intermodal terminals, and it is considered that the market is not "free", i.e. that, under the same conditions, the services are not available to all potential users. It is clear that a large share of problems has business-to-business relations, but insufficient participation of qualified staff also plays a big role.
Service offer (identified as a problem in three countries) refers to inadequate, non-existent or poor service offered by logistics providers or carriers, primarily in the rail and water transport. It can be the result of lack of understanding of market needs, inadequate competition (because companies do not compete for a "piece of cake") or company ignorance. This problem has been identified in Hungary (MoTTE, 2007; MoTTE, 2014), Croatia (MoSTI, 2014) and Moldova (GovMD, 2013). The problem may also be related to the absence of a complete range of services, or the absence of VAL (Value Added Logistics) services, especially when involving rail transport in the intermodal chain (specifically prominent in Hungary (MoTTE, 2007)). This problem is conspicuous in Moldova, as there is a lack of appropriate intermodal topics (GovMD, 2013). The situation has been additionally made difficult by the bad influence of the national railway operator, which was previously described.
The problems of financial nature make up 52% of identified problems in national strategic documents of DR countries. Typical representatives are traffic infrastructure (17.06%), intermodal terminals (5.21%), terminal network (4.27%) and vehicles (3.79%). The problems directly related to these IT subsystems make around 30% of identified problems. In addition, significant financial problems are related to ICT (7.59%). In order to solve the lack of funds in the budget, traditional approaches are mainly used. These are additional roadside payment charges, excise increase, external costs and likewise. Alternative approaches, such as the development of different forms of public-private partnership (PPP) (e.g. in the Czech Republic, MoT, 2014) or concessions (e.g. in Bosnia and Herzegovina, MoCT, 2016), are significantly lower in use and in plans.
The strategic documents of the more developed countries are dominated by problems that require significant financial resources (Germany - 89%, Austria - 80% of identified problems). Of those non-financial nature in Germany, PPP is allocated, and in Austria, insufficient resource utilization. Non-financial problems make up the majority of identified problems in Ukraine (65%), Hungary (64%) and Serbia (60%).

4. Situation Across Micro - Regions

Given that DR countries differ significantly in terms of their economic characteristics, the level of development and application of IT technologies, and for the purpose of comparative analysis of the problem, their grouping was carried out in three Danube micro regions (DMR):

- DMR 1: Austria, Germany and Slovenia;
- DMR 2: Czech Republic, Slovakia, Romania, Hungary, Moldova and Ukraine;
- DMR 3: Bulgaria, Croatia, Bosnia and Herzegovina, Serbia and Montenegro.

The number of problems identified in strategic documents by DMR varies, among other things, due to the varying number of countries that they cover. Only 12.80% of the total identified problems are in DMR 1 countries, of which 2/3 are in Slovenia. The rest of the problems have been almost evenly distributed in DMR 2 (94 problems) and DMR 3 (90 problems). Transport infrastructure and business issues are the most critical areas for the number of identified problems in all three DMRs (table 3). In DMR 1, problems related to terminals (especially the problem of outdated technology in terminals) are distinguished, DMR 2 issues related to ICTs and projects, primarily IT development plans, and in DMR 3 problems related to finance.

Table 3
Areas and problems across DMRs

Areas of problems	DMR 1		DMR 2		DMR 3	
	No. of problems	Frequency (%)	No. of problems	Frequency (%)	No. of problems	Frequency (%)
Business	4	14.81	23	24.47	18	20.00
Transport infrastructure	7	25.93	16	17.02	13	14.44
ICT	3	11.11	10	10.64	9	10.00
Finance	3	11.11	5	5.32	12	13.33
Ecology	3	11.11	5	5.32	6	6.67
Projects	0	0.00	9	9.57	4	4.44
Terminal	4	14.81	5	5.32	2	2.22
Border crossings	1	3.70	3	3.19	5	5.56
Terminal network	1	3.70	4	4.26	4	4.44
Vehicles	0	0.00	4	4.26	4	4.44
Workforce	1	3.70	1	1.06	4	4.44
Law	0	0.00	2	2.13	4	4.44
Institutions	0	0.00	2	2.13	2	2.22
International cooperation	0	0.00	1	1.06	2	2.22
Politics	0	0.00	2	2.13	1	1.11
Flows of goods	0	0.00	2	2.13	0	0.00

By analyzing the problems in micro regions from the aspect of the necessary investments for their solving, it can be concluded that financial problems dominate in the DMR 1 (77.78%), while in the other two micro regions, non-financial problems have a slight advantage (DMR 2 - 51.06%, DMR 3 - 52.22 %) (Figure 1).

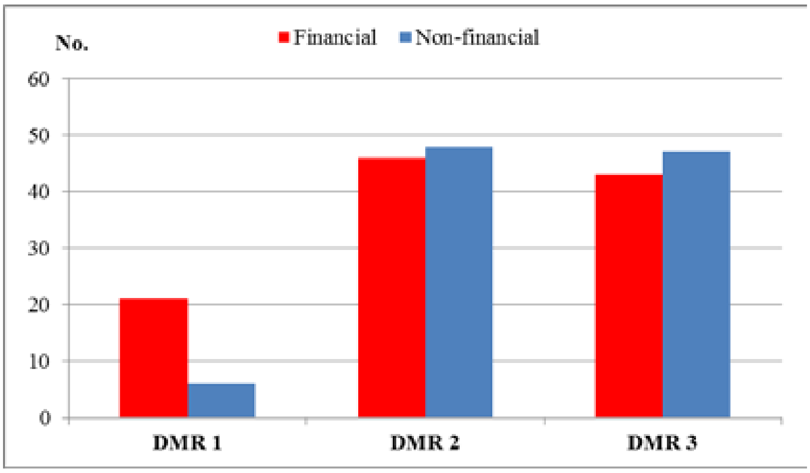

Fig. 1.
Non-financial and financial problems in micro - regions

In addition to the previously described business problems, corporate transparency has also been recognized in six, mostly less developed countries. The resolution of the problem is perceived as the adoption of the rules that will "force" companies and authorities, mainly the state, to make more transparent operations that will provide insight into their availability of resources, employment of new employees and similar (MoTMA, 2010).

Representatives of the problems in the field of transport infrastructure are railroads, travel time (caused by poor infrastructure) and connection of hubs (it can also be treated as a problem in the terminal or terminal network area, but it is closer to a particular area of the infrastructure since it directly refers to the connection, primarily railways). Railway transport makes most of the problems in the field of financing - financial sustainability of railways, financing of railway rolling stock and non-profitability of railway companies.

The lack of ICT systems has been recognized in all DR countries except in Bosnia and Herzegovina and Ukraine. Application of the European Rail Traffic Management System (ERTMS), River Information System (RIS), Intelligent Transport Systems, and the New Computerized Transit System (NCTS) have been mentioned. Since digital, e-logistics is the most important component of competitiveness, the applying of these, often expensive, systems does not belong to the VAL service domain, but is the necessary one. It is important to note that it is not enough to provide ICT support to individual modes of transport, but also more importantly - to ensure the connection between them, i.e. coordination, information sharing, response, synchronization and mutual cooperation.

The issues of a non-financial nature that are often neglected are those related to the law and the institutional framework in the field of IT (together, they make up less than 5% of identified problems). Intermodal transport requires the same treatment as other types of traffic (road, rail, water or air), since it represents a system for itself. If the EU goals are sustainable development, greater use of environmentally friendly forms and transport technologies, then the development of all individual aspects, should be in the function of IT. The law and regulations need to be updated and adapted to the needs of society in order to preserve the environment, but without imposing unjustified obstacles and restrictions on the work of the operator.

When it comes to critical areas for IT development, it is also necessary to mention the problems that are specific or omitted in the national strategic plans. Among the specific problems, there are the lack of projects for addressing bottlenecks, the lack of research and studies (recognized only in Hungary (MoTTE, 2007; MoTTE, 2014) and the lack of freight transport centers (FVs), as the largest form of logistics centers (Zečević, 2006) (identified only in Bulgaria (MoTITC, 2010)). Although they have been rarely recognized as problems of IT development, the mentioned problems are consistent in a much larger number of countries, especially developing countries. The problem of using subventions (therefore, subventions exist) is recognized only in the Czech Republic (MoT, 2014) and Hungary. Similarly, the problem of centralized railway management was identified only in Slovakia (MoTCD, 2016) and Serbia (MoCTI, 2008; MoCTI, 2015).

The number and category of problems that exist, but were omitted in the strategic documents, vary by country. However, at the level DMR 3, among others are the following: the use of subventions and the connection of city terminals, projects addressing solving bottlenecks and the impact of the national strategic operator. In the DMR 2, no novelties were found regarding the maintenance plans and the lack of FVs, space in the ports, and the lack of skilled workers. Germany and Austria as the most developed countries of the DR have the least IT problems, but in Slovenia, as a DMR 1 member, they are not identified, and there are problems of lack of FVs, IT development plan, navigation conditions and obsolete and insufficient vehicles.

5. Conclusion

Knowing the problem enables the setting of targeted actions and more efficient and effective realization of goals. Without identifying the problem, it is not possible to remedy the deficiencies and improve the situation, which can lead to multiple resource spending, prolongation of the moment of benefits realization and their reduction, and generating

losses in terms of failure to meet requirements in the areas that would otherwise have priority. In order to maximize the benefits and efficiency gains, while defining the problems, it is necessary to determine the priorities for solving. The risk of problems is increasing if it is not recognized, as a result of lack of attention and knowledge of the situation.
Research into strategic documents has shown insufficient knowledge of IT systems and inadequate treatment of areas in most DR countries. Critical areas of the whole region are business problems, transport infrastructure and ICT, of which at least the last two can be treated in a similar way, or have similar solutions in different countries. Examples of interventions in the field of transport infrastructure would be, among others, the removal of bottlenecks and modernization of railways, the stimulation of the reuse of industrial tracks, in which case the connection with ports is justified, and also with all categories of logistics centers.
In general, it can be concluded that better knowledge and promotion of IT systems, especially in countries in which it is not satisfactory, would bring significant benefits to both providers and service users. It is important to note that IT problems are not only at the operational level (such as the choice of means and/or proper use of the system) but also at somewhat higher levels (where the emphasis is on cooperation, networks, terminals and services, awareness raising), to the level of institutions and regulations.

MODELLING SECURITY OF INTERMODAL TRANSPORT BY APPLICATION OF PETRI NETS

Nermin Čabrić[1], Snežana Tadić[2], Slobodan Zečević[3]
[1] Ministry of Communication and Transport B&H, Railways Regulatory Board, Doboj, Bosnia and Herzegovina
[2,3] University of Belgrade, Faculty of Transport and Traffic Engineering, Belgrade, Serbia

Abstract: The security of intermodal transport (IT) depends on the level of security of all links of the intermodal transport chain (ITC). The basic element of the IT system is the intermodal transport unit (ITU). ITU is a token, and its movement through the intermodal network makes a dynamic change in the system. An analysis of a secure IT system that is complex, dynamic, and targeted towards a particular goal requires the modelling of the structure and the transfer of units in the chain links. These analysis can be performed using Petri nets which is a convenient tool for displaying a complex system and validating the characteristics of its subsystems. This security modelling approach allows you to see the functioning of the ITC in a real environment.

Keywords: intermodal transport, intermodal transport chain, security, modelling, Petri nets.

1. Introduction

Intermodal transport (IT) is a very complex process, involving multiple modes of transport and different participants with different interests and goals. The security of an uninterrupted transport chain, or end-to-end security, is one of the key problems IT is facing with. Achieving a certain level of security, or protecting the system from stealing goods or vehicles, attacking drivers and illegal transport of people and goods, are the constant challenges that all participants in the continuous transport chain face with. The intermodal transport chain (ITC) is exposed to illegal activities and the risk that the intermodal transport unit (ITU), transport vehicles or traffic infrastructure will be exposed to crime or used by terrorists and become the object of a terrorist attack. Weaknesses are becoming increasingly apparent at connecting points of different modes of transport - intermodal terminals. In order to protect them, various security checks of transport means and ITUs are undertaken. In this paper, using Petri net, a sub-module of unobtrusive checks was developed in the intermodal terminal in which there is ITUs transfer load.

2. Petri Nets and Intermodal Transport

Petri Nets are recognized as a convenient, direct and efficient tool for modelling, analyzing and evaluating systems with discrete events. They give graphic and mathematical support to simulation, quantitative and qualitative analysis and system synthesis (Dong & Chen, 2001). They can systematically display all activities, shared resources, synchronized or parallel processes, etc. (Murata, 1989; Peterson, 1981). Numerous possibilities of application have influenced the development of various types of Petri nets: ordinary, black and white, colored, weather, stochastic, modular, etc. In an uninterrupted transport chain, IT is included in the category of systems with discrete events. The behavior of a complex system, such as the IT system, can be described on the basis of the system state and the change in the application of Petri nets. Although Petri nets can not present the complexity of operations in IT, their graphic aspect gives some advantages in displaying and testing the model. Cities represent resources, capacities or conditions, while crossing represent the flow and activities in the terminal. Tokens represent the ITU or the means by which the factory units are transported. ITC is a chain of events, and each link of a chain is a place of potential threat to security and safety. Since all chain links are not as secure and safe as possible, the Petri nets method provides the ability to identify critical points and control discrete chain activities.
By reviewing the literature, a large number of papers were observed with Petri nets for modelling logistic systems and intermodal terminals as a system with discrete events. The application of the stochastic Petri net is common in the process description in intermodal terminals (eg, Fischer & Kemper, 2000; Gudelj et al., 2010), modelling and analysis of logistic systems and chains (e.g., Labadi et al., 2008; Chen et al., 2005; Chen et al., 2003; Chen et al., 2002). There are also numerous examples of the implementation of the Petri net planning and resource managemen, the assessment of operational perfomances, the level of efficiency, and the identification of bottlenecks of the intermodal terminal based on the corresponding system performance indicators (e.g., Di-Febbraro et al., 2006; Dotoli et al., 2006; 2010; Dotoli et al., 2014; Cavone et al., 2017). Time Petri Nets have proven to be a good tool for analyzing logistic systems (eg. Labadi & Chen, 2010) and assessing the performance of the intermodal transport net (Boschian et al., 2011).

3. System Description

Most of the trade that is being realized by ITCs is repeated. These chains include large and well-known operators working on predictable templates and which customs can easily control. In order to secure customs chains, customs should be familiar with terrorist operatives, false companies, zones of action and certain threats.
Efficiency of ITC implies unhindered flow of goods without stopping and slowing down ITU trends. In each of the links of the continuous intermodal supply chain (road transport at short distances, in the initial and final phases of the

[2] Corresponding author: s.tadic@sf.bg.ac.rs

chain, intermodal road-rail terminal, rail transport, port container terminal, maritime transport) there are certain tools and measures to reduce the security risk. Every measure and intervention to increase security in the chain should be well thought out. The number of manual interventions and the duration also. Each additional minute for the processing time of the ITU would be problematic due to their number in the supply chain. In order to avoid duplication of operations in the chain phases and shorten the timing of customs operations, security enhancement measures should be integrated and located at intermodal terminals. This would not only shorten the timing of the chain realization, but would also reduce the risk of the possibility of using ITU for illegal purposes. Intermodal terminals are an important link on the transport route of goods from the manufacturer to the consumer and represent the so-called 'Black spots', places of increased risk for the security of the intermodal supply chain. Since security is more endangered when the ITU is stationary, or when it is waiting for loading, overloading or unloading, the goal is for processes in the intermodal terminal to run fast.
In all chain links, periodic checking of the security system should be carried out, in order to detect weak points. In accordance with the checks, but also technological development, the unit review procedures are also proposed and proposes the application of new, economically acceptable technologies.

4. IT Graphical Security Model

The paper presents the application of Petri nets for monitoring the secure movement of ITUs (tokens) in a complex, stochastic and dynamic ITC system. Petri net of complex systems is obtained by joining Petri nets of its subsystems. Merging can be accomplished by joining common sites of the Petri subsystem nets, which would mean that subsystems share resources; and by merging common transitions of Petri nets of the subsystem, which would mean that the subsystems change with the occurrence of the same event.
In the intermodal supply chain, different modes of transport and various intermodal terminals are included. All the links of the complex ITC system (sub-systems) can be presented to Petri nets as sub-modules. Given that subsystems share resources such as ITUs (container, interchangeable transport court, etc.) and a vehicle (truck, railway wagon, ship, etc.), Petri net of systems is obtained by merging common sites of Petri subsystem nets. Connection points are also the points of transport of ITU from one way to another.
In order to increase ITC security, each sub-module (chain link) can have an ITU security sub-module. The sub-module of the unobtrusive internal ITU test in the road-rail intermodal terminal is shown in Figure 1. A container loaded on a road vehicle is transported to the terminal where the checking of accompanying documents is carried out at the entrance gate. The vehicle then goes to the zone of the security check where an unobtrusive method - scanning and gamma rays – is used for checking possible presence of unauthorized content (people, radioactive materials, etc.). The procedures vary depending on the results of the scan test. If the control result is positive, the container is opened and the visual inspection of the interior is performed. If everything is correct, the container is closed, sealed, and directed to loading. Transitions t4 and t5 (Figure 1) allow adjustment of the time so that the scanning process can only be performed during the terminal working hours. The NetDraw program, version 3.4.2-10.9.15, was used to view Petri nets.

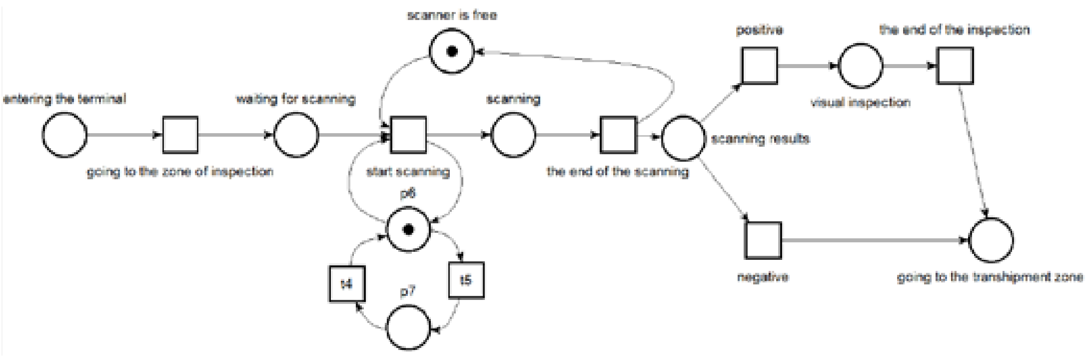

Fig. 1.
Sub-module of unobtrusive ITU checks

Figure 2 shows the complex ITC system obtained by joining Petri nets of the subsystem (chain link) with a submodel of unobtrusive check in the rail-road, intermodal terminal.

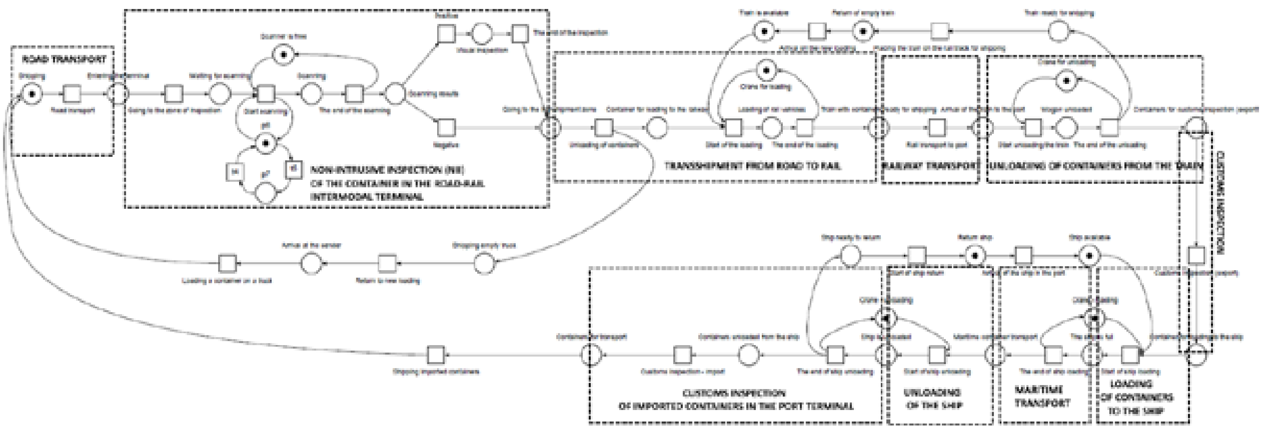

Fig. 2.
Sub-systems of the complex ITC system (Čabrić, 2017)

5. Modelling the Procedure of Unobtrusive Checking

The ITU that moves through the ITC can be treated as secure or as a potential threat, i.e. as a 'trojan'. The term 'trojan' is used as an association to the Trojan Horse which is run by a corporation established with the intent to deal with illegal, terrorist, and similar activities. When incepted, the corporation works in accordance with the law for a long time, until it has gained the trust of the customs, the police and other competent authorities, and then switches to illegal actions in the international transport of goods.
It is considered that the ITU is secure when, in accordance with national rules and international agreements, all participants in the processes of packing, loading, sealing, transhipment and shipping carry out the procedures related to increasing the level of security of the intermodal transport chain of supply. In accordance with international standard ISO 17721, after loading of goods, the ITU is closed and sealed with a unique identification number. If one of the following codes and standards apply in the ITC:

- ISPS code (security or ship, port and port equipment);
- Standard SAFE (developed by the World Customs Organisation, facilitates customs processes and procedures);
- CTU code (security during loading, CTU security seals - information document IM9),

and if all participants, and therefore providers of services, are granted the status of an authorized economic entity, one can speak of a secure intermodal supply chain. The status of an authorized economic entity is obtained by checking through certain procedures applied by the Member States of the European Union.
The security of the transport chain is based on efficient risk management based on the exchange of information between participants, in order to create a synergy of customs administrations and joint efforts to combat illegal activities in the supply chain. By establishing an adequate system for collecting information about ITC participants, the security check of the ITU is strengthened. The objective is, based on the information gathered, to separate potentially dangerous and potentially safe ITUs, which will reduce the security risk, thereby increasing the ITC security.
The discovery of ITUs with unauthorized content (migrants, chemical and biological weapons, explosive devices) is based on previous information, so the place of dispatch of goods, or the starting point of ITC has a special significance. Timely identification of the ITUs with a security risk recognized at the starting point of the chain makes it impossible for its arrival to intermodal and port terminals. In addition, checking the unit at the beginning of the chain makes it possible to know what is going through the ITC before the shipment arrives at the destination. By detecting problematic shipments and preventing their arrival at the end of the chain, Europe's internal security and the security of international trade are increasing.
Modelling the security of intermodal transport in the way that the ITU is viewed as certified or safe, and as a possible trojan, can be done with the CPN Tools, the tool for modelling colored Petri Nets. The tool provides the ability to check the layout of the terms involved in creating the code that defines the form of the net 'step by step'. A quick simulation allows the management of colored Petri nets, and the addition of a time component enables simulation of the time Petri nets. Complete and partial conditions can be analyzed, and standard results and reports contain information about the properties of Petri nets, such as limitation, liveness, reversibility, covertability and persistance.
An example of a colored Petri Net, made using the CPN Tools, as a submodel of an unobtrusive security check in the terminal, is shown in Figure 3. Let us assume that, at the entrance of the scanner ('Entrace scanner'), there are two types of units (UTIs in the figure): A – 'trojan', potentially dangerous, has a certain level of safety hazards, and B – 'certified' safe. Units range from 'Entrance Scanner' to 'Choice' where the type check is performed, after activating the 'Select' switch that is operated by 'Traffic_light' by turning on the light at the traffic light. By identifying the unit type, UTI is defined. After identifying the type, the unit is directed to one of two processes. Units that carry the attribute 'trojan' go for further checks (scanning, sealing, opening the door, visual inspection of the interior, measuring the level of CO_2 in the interior, etc.). Units that are based on previous information are considered safe, carry the attribute 'certified' and continue to move through the ITC. When the time component of the time is introduced, the colored Petri grid passes

into the time-colored Petri net. Assuming that the movement of the unit from the 'Entrance scanner' position to the scanning site takes 3 minutes, and the process of marking/assigning the unit to 'certified' or 'trojan' takes 8 minutes, then the activation of the passage is not current, but is timed by the length of the process.

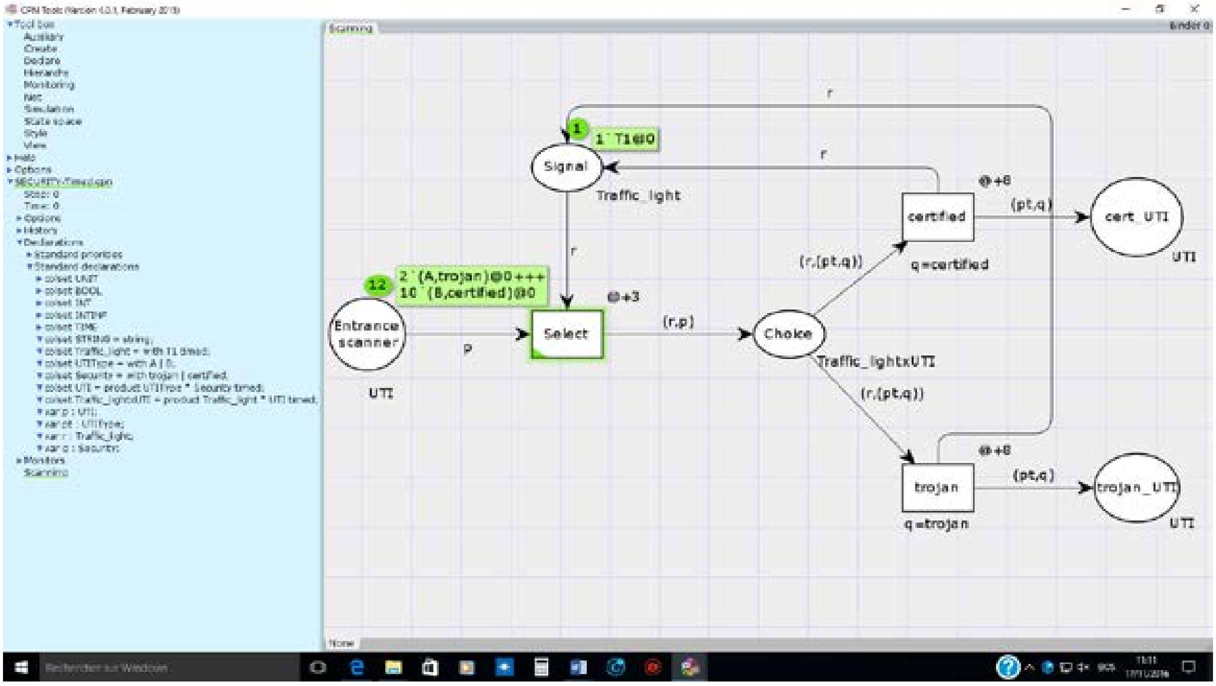

Fig. 4.
Modelling security for coloured Petri Nets using the CPN Tools (Čabrić, 2017)

6. Conclusion

Complex systems require the development and application of efficient methods and tools for their planning, optimization and management. Petri nets, as a graphic-mathematical tool, are suitable for modelling and designing various types of dynamic, discrete and distributed systems.

Planning and management in the intermodal transport chain, as a complex and dynamic system, requires simultaneous and comprehensive monitoring of all subsystems that are linked by the chain. The paper presents the possibility of modelling the security of the chain using Petri nets. Petri nets of systems are created by joining the common sites of Petri nets of his subsets. It is possible to develop sub-modules of ITU security checks in each of the subsystems. Considering that the danger of compromising security is greatest at the points of crossing different types of transport, the paper presents the model of unobtrusive security check in the road-rail intermodal terminal using the time-colored Petri nets. Terminals take all measures of directing ITU subject to security checking procedures at the very entrance, and before shipping from the terminal, latest.

Abstract: CELP - The Central European Logistics Portal has solved the problem of a complete solution for editing and trading a system of international logistics portals over several years. Within this research study, team focused on the correct definition of the scope and utility values of the managing editorial system. The needs of the content management system have been defined as the providing information content, the booking of paid portal content, the economic system of cross-billing of business activities, the marketing support of individual logistics portals involved, the emphasis on the importance of mutual communication between editorial offices and the automation of shared content. After work on individual input analyzes of national logistics environments, the team proceeded to design the portal structure and to program the target SW itself. In the last phase of the project, the research team focused on supporting the basic logistics portal by developing native mobile applications that have enabled portal users to access the daily access to daily information from a logistics environment. The entire project has been implemented within the framework of the Eureka International Program and has been supported through the Ministry of Education of Youth and Physical Education of the Czech Republic.

Keywords: Logistics, Information Portal, Data Exchange, Sharing the Information.

1. Introduction

The project responded to the situation within logistics sector in Central Europe and to the absence of an integrated logistics information center for collecting, sorting, storing and distributing proven and up-to-date information from the logistics field. Outcome of this project *The development of the Central European Logistics Portal* should take over the role of this logistics center in Central Europe. The uniqueness of this solution consists in its operability, timeliness and, last but not least, integrity. The result of the project is to unify SW platform which allows research users to identify and maintain logistics information on the basis of research findings of entry constraints in individual participating countries by involving individual national logistics information portals in an integrated European multilingual environment.
This solution contributes to the greater competitiveness of logistics companies, their greater cooperation and the awareness of logistics users about the most suitable solutions for their needs and enables to make a decision to managers of individual companies based on correct and comprehensive information in the field of logistics processes. The solver position on the Czech and European market has given the assumptions not only for the successful solution of the project, but also for the commercial success of the solution results. The application of the solution results has been applied in the market in a partial way already during the project solution. The use of solution results has already been used in the verification process, first of all, with existing local customers using other information channels offered by the solution, and subsequently, with new transnational customers who will be able to make full utilization of the project European dimension (Bartuska *et al.,* 2016), (Kampf *et al.,* 2017).

2. The Central European Logistics Portal

The purpose of the project has been to research and develop the comprehensive European Information Logistics Portal, which addresses by the mutual information exchange among each other in the field of logistics, logistics processes and all elements of the logistics chain in the European region with an emphasis on the development of this sector in the Central European micro-region. This information is especially important for the optimal planning the logistics processes across 3PL logistics companies, transport companies, production plants, retail chains and other entities that are implementing the principals of logistics services. This information exchange is related to transport securing the logistics needs of individual entities, the safety of the operators involved in the logistics chain and the economic benefits of the entities using the portal services. Furthermore, it will actively contribute to the mutual cooperation of the already neglected logistics sector, to its development and to raise awareness of such an important sector of the national economy in the context of entire Central European region development (Buková *et al.,* 2016), (Kubasakova *et al.,* 2014). Advantages of the solution are, as follows:

- the proper up-to-date information for which the portal operator guarantees in one place,
- expertise,
- interconnection the industry news with the current offer of advertisers and particular database:
  - logistics providers,
  - carriers,
  - safe suppliers.

The portal, as a result of the project solution, serves:

[1] Corresponding author: jiri.kalensky@mdcr.cz

- to logistics operators for trade with given suppliers of the sub-logistics services in a region, which are not known well enough by them, and thus allows for a greater security of their own investments in the Central European region,
- to suppliers of equipment and technology for individual logistics chain members in order to be able to verify the existence of the given entity in the country, including the core credit rating of customers and other suppliers,
- to logistics customers, in a field of partners suitability assessment to meet their logistics needs in other European countries.

The portal is oriented towards top and middle management of the above-described companies in their decision-making process and for a broad logistics audience that provides free access to the latest logistics information in their country and other European countries. In this respect, the Central European Logistics Portal (CELP) has a positive impact on the logistics training development, and thus enables schools providing logistics education to access the most up-to-date information in the field, to the latest technological innovations, but also to raise awareness and involve their students in the production professional information within the portal.

In the future, individual involved national portals will be operated in the form of franchise using software support in this project of the developed communication environment, which ensures the editorial activity of the portal and the data transfer between the individual national portals that will be involved in the system. A properly set environment allows for simpler information exchange between the transnational part of CELP and individual national portals, which also contributes to linguistic multifunctionality, where the transnational part of CELP is implemented in English mutation and individual national portals are operated and will be operated in combination of English mutation and national language mutation.

It also allows direct verification of the logistics entities reliability incorporated into the portal through any national portal, or directly through the transnational part of CELP. The precondition for the target state after the completion of the project is to involve as many national portals as possible. It will be possible on the basis of established communications platform after the completion of all the project phases. The gradual engagement speed of the other national portals will depend on the business potential of the given field and the choice of a suitable partner for the franchise CELP. As part of the project outcomes, it is not only to reach readers and customers with the help of a web service (it is meant by the network of the news portal visible and readable on computers), but also its transmission and visibility on mobile devices (Jurjens, 2005), (Lizbetin *et al.,* 2016).

Status after the end of the project is depicted in Fig. 1.

Fig. 1.
Status after the end of the project
Source: Authors, based on the final report of the project

3. Project Objectives and their Accomplishment

The main partial objectives of project are summarized in following Table 1.

Table 1
The main partial objectives of project

Title	Start the solution	Ending the solution
Analysis, research and development of the application platform /environment and the content management system	10/2015	12/2015

Title	Start the solution	Ending the solution
Implementation, construction and launch of the portal for the web environment and implementation and putting into operation of individual national versions of the portal	01/2016	12/2016
Research and development of mobile applications and routine operation, including the connection of databases to national registers	01/2017	12/2017

Source: Authors, based on the final report of the project

3.1. System and Data Analysis

At this phase, the research team analyzed all the key conditions and circumstances that are important and influence the way of the project solving. Within this framework, all the initial conditions of the project solution were determined; system architecture and individual modules were designed. A diagram of classes emerges from the described links in process analysis. Further, a data model was developed and the system platform was defined. Data with respect to the HW project support was collected and analyzed. The HW demand of the SW was determined and the individual HW components required for long-term sustainability of the project were defined. At this phase, data and information was also associated, described and analyzed with regard to the communication and user environment of the project (Sýkorová and Čverhová, 2011).

3.2. Research and Development of Application Platform, Editorial System and Basic Application Modules

Already in the first year of the solution, the research team performed the preparation for programming and testing the the environment, the editorial system and individual application modules. Following the analysis, it was decided to start the administration modules development, news, users, business and marketing. Next year, the research team continued its work on implementing the portal in a web-based content management system and implementation and commissioning the individual national portals in a web environment. The results consist in platform/environment/editorial system, administration module, news module, module users, module store, marketing module, and user guide in the online application environment.

By these, work on an editorial and publishing system suitable for the administration of information portals in a web environment was completed. When implementing national portals, the research team conducted localization for individual language mutations. For each national version, national SEO (Search Engine Optimization) strategies and keywords for each environment were added. Following the implementation, the first phase of national portals testing was to carry out the communication testing national portals with the central transnational environment of the CELP.

Timing the individual objectives was spread over the second year of the solution. Researchers' capacities were regrouped according to immediate needs of solved partial requirements and within the determined objectives, analyzes of web environments and portal strategies including SEO strategies, communication environment test records, records of updating the programming documentation, and user manual were prepared.

Portal design for communicating with the web environment includes the following results (Bai, Y. 2011), (Chan, 2014):

- data model design,
- user interface design,
- specific address book and event calendar,
- programming documentation development.

Suggestions for national portals to communicate with the national web environment include the following result:

- Defined .po. and .mo. files containing translation for individual language versions of portals.

During the project solution, the researchers worked on partial requirements of internal procedures. To manage the programming documentation, cloud tools for managing GITHUB source code were used. The analytical documentation was kept in the prescribed form in the cloud of MS, its Office 365 - sharepoint and the document management server. UML data models for designing data structures and processes have been created and stored in the enterprise architect modeling tool (Rosenberg and Stephens, 2007).

3.3. Implementation and Design of Web Portal

In this sub-phase, the research team focused on web environment analysis, the design of a portal strategy including SEO strategy and keyword definition, the design of a graphical interface for the portal and the implementation and programming of the web interface portal in the new content management system.

In order to create a graphical interface for the portal in a web environment, a graphic template was defined and selected and the appearance of the website portal and the content portal were implemented and programmed.

The results were, as follows (Naumov and Kholeva, 2017):

- web site analysis, portal strategy development including SEO strategies and keyword definitions,
- portal graphical interface,

- portal implementation in the content management system.

At this phase of the project, a number of consultations were carried out. Based on these consultations, requirements and comments have arisen to the individual modules of the content management system and new requirements for plug-ins. Following the negotiations and evaluation of the comments, a comprehensive review of the proposed solution was carried out which altered the visual and enriched functionality of the application. The following plug-ins were added to the original solution:

- business directory,
- event calendar,
- advertising space.

Besides modifying and adding modules, it was necessary to solve the development team with more general features, including:

- logging,
- administration of the application,
- sharing content between individual portals,
- emailing portal messages,
- data synchronization.

Last but not least, the graphic design and portal layout was made. This proposal was converted to HTML5 with the necessary functionality. The research team focused on debugging the portal and applications for most of the IE9, IE10, IE11, Firefox, Safari, Opera, Chrome and Edge browsers, a responsive three-column look, a page load speed of 2.63 seconds; page size 1.42 MB; number of requests 93. AJAX search service and Google analytics support also were implemented by the team.

After successful implementation of the CELP transnational environment, the research team focused on research on national environments, selection of national portals operators, research and analysis of the communication environment, programming the communication environment between the transnational CELP environment and national portals. The testing communication environment functionality, the testing operation and the debugging portal were followed. During solving the Eureka project, the scope of involving national environments in the project, and thus all the works on national environments, were determined to be national portals:

- Czech,
- Slovak,
- Hungarian,
- Polish.

As a result of this phase, four national portals for web-based environments were put in place according to individual locations. Unlike solutions in a transnational environment, the following features were developed, programmed and complemented based on a series of consultations in each of national environments (Bradford, 2012):

- communication between portals,
- sharing published content among portals,
- sharing the advertising space and placing it among portals.

The graphic design and its functionality were implemented in the editorial system and the result was shown, first of all, in the transnational environment of CELP and its website www.eurologport.eu. The pages were successfully tuned and run in trial mode.

3.4. Research and Development of Mobile Applications and Routine Operation, Including the Connection of Databases to National Registers

In the last year of the project, works on the project solution continued with the native mobile applications development for the largest and the most important mobile operating systems. During the mobile applications development, the research team emphasized native development using modern technologies and standards and a simple, user-friendly environment with easy control. The analysis of individual national environments for the use of national general registers, their use for determining the creditworthiness of the involved entities and the mutual communication of the individual portals and their links to the individual national portals was carried out in parallel. At the end of the project, works to run the whole solution into routine operation were made. From this phase on the project participation, the following partial objectives were obtained (Sklar, 2016), (Tupas et al., 2016), (Williams et al., 2015):

- mobile environment analysis,
- mobile app testing records,
- new registry module,
- records of updating the programming documentation,
- a processed user guide,
- a final technical report.

Results of this phase formed the prerequisites for the successful project sustainability and its further development within the business and strategic options of the investigators.

3.4.1. Research and Analysis of the Mobile Environment

This phase had the aim to describe all the key conditions and circumstances that were important to influence the development of CELP's mobile applications from an analytical point of view. Within this phase, all uniform starting conditions of the solution were determined. A uniform process and functional diagram was created for all mobile applications. Also, a single data model was developed and mobile app platforms were confirmed. This phase was also intended to gather, describe and analyze data and information with respect to the communication and user environment. The result was to process analysis in printed and electronic form in the structure described above in this chapter.

3.4.2. Development of Native Android and iOS Apps

First of all, the solution analyses and specification were done. In addition, graphical design of individual screens (GUI) and communication protocol (API) were made. Implementation itself and application programming were performed. At the end of this phase, the team tested mobile apps, debugging and releasing them on Android Market and the iTunes/App store for free download. The results of the phase were, as follows:

- native Eurologport for Android,
- native Eurologport application for iOS.

Applications have been successfully tuned and run in trial mode. The Eurologport Android mobile app selling page on Google Play is illustrated in Fig. 2.

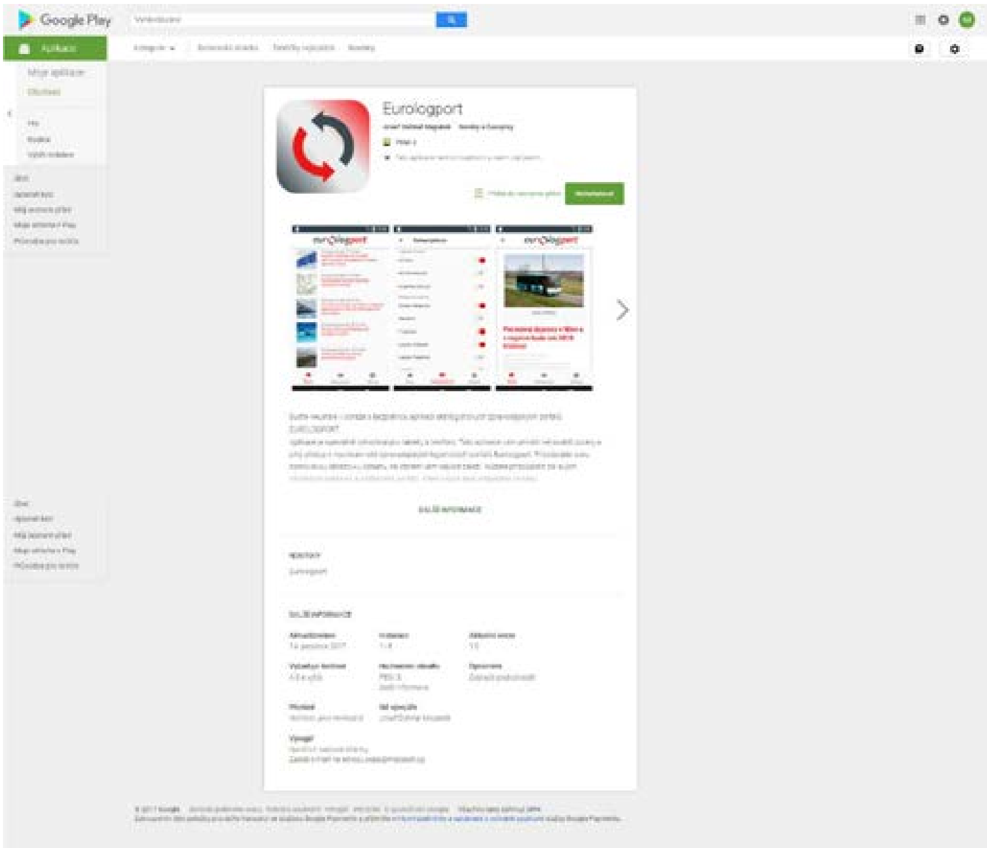

Fig. 2.
The Eurologport Android mobile app selling page on Google Play
Source: Authors, based on the final report of the project

3.4.3. Bindings of the Databases to the National Registry

First of all, the research team prepared user workstations and streamlined communication with real IS users. In addition, an analysis of the national legal restrictions for entries into public registers, the development and programming the communication interface between the CELP application modules and the national registers were carried out. Trial operation with selected system users represented the completion of this phase of the solution. A number of consultations were conducted at this project phase and, based on these consultations, a number of requirements and comments were developed for each module of the registry module. The registry was programmed to display information both in the application and on individual portals, such as viewing information for the corporate directory plug-in reader. In the first phase, it was programmed for existing portal sites. The results were, as follows:

- enhanced registry module in the application for individual portals,
- linking and validating information entered into the corporate directory with each relevant national registry,
- view information about validating data about the observed company in the corporate directory.

After the first phase, the next phase smoothly continued while it was intended to investigate the differences in other national environments, analyze the needs of programming the differences in national environments, develop and program a universal communication module for different national environments, specify the structures of the required databases for national portals. After programming the necessary connections, the research team proceeded trial operation and tuning of the universal national module. This phase represented a prerequisite for the subsequent operation of the information system itself. Module Registry was modified to make it easier to connect to other national and transnational registers (Polgar and Adamson, 2013), (Rajlich, 2011).

3.5. Launch into Routine Operation

At this phase, the research team focused on deploying the developed and tested solution in routine operation and verifying individual communication links. Within this phase, the final report of the project was processed as well. The objective was to implement the final integration and stress tests of the CELP information system designed in the project previous phases. From the authentication process, recommendations to modify individual functionalities to optimize the operation of CELP's information system and its transnational communication environment were made. The results were, as follows (Krásenský, 2010):

- prepared project final technical report,
- processed test protocols,
- documentation and records from authentication and testing operations.

3.6. Testing, Debugging, and Bug Fixes

During the project, the research team used and tested several of the following logical SW areas:

- programming verification of the SW and its parts in following areas:
    - platform,
    - content management system and publishing system,
    - applications,
    - web template and its components,
    - mobile application,
- user operational testing:
    - user application testing,
    - user web portals testing,
    - user mobile apps testing.

During testing, tools available in the SW environment were maximized. The cloud tools for managing GITHUB source code were used to manage and store the test documentation. Testing was performed in a group of the following experts:

- Josef Dohnal (Chief Programmer and System Architect),
- Lenka Dohnalová (Web Specialist),
- Michal Drha (Sales and Marketing Specialist),
- Jiří Kalenský (Logistics Specialist).

4. Discussion

Throughout the project, following systems and applications were gradually started to run in routine operation (CodePeer, 2013), (Fauzi, 2012):

- universal platform and editorial and publishing system for managing websites and applications,
- project applications,
- individual web portals for the Internet environment in the target markets of Central Europe, the Czech Republic, Slovakia, Hungary and Poland,
- mobile applications for Android and iOS operating systems.

All systems and applications have been deployed and run without major operational problems.

4.1. Universal Platform

The result was to design a universal programming platform for editorial and publishing systems and web applications including source codes (specimen, see Fig. 3).

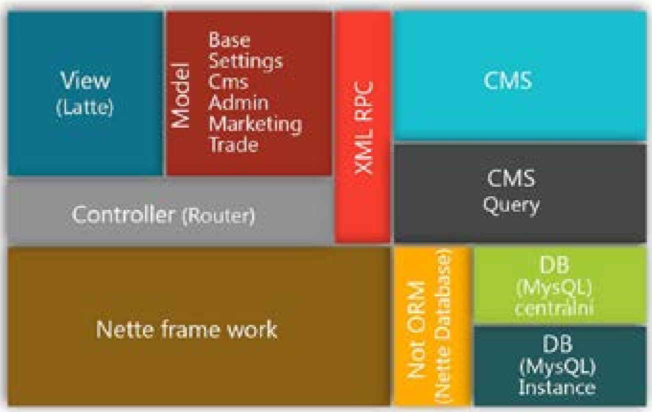

Fig. 3.
A universal platform for creating web applications
Source: Authors, based on the final report of the project

4.2. Editorial and Publishing System

The result was to design an editorial and publishing system suitable not only for the information portal administration processes in a web environment including source codes (Jurjens, 2005), (Kampf et al., 2017).

4.3. Project Applications

The result was to design web application including individual user modules for managing and running the application. The application has been implemented and running on individual web portals with the following path http: //www.eurologport.XX/elp/. During the project implementation, the application was implemented and installed in a transnational CELP environment, and in individual, national environments for the Czech Republic, Slovakia, Hungary and Poland on individual national domains of the Eurologport (specimen, see Fig. 4).

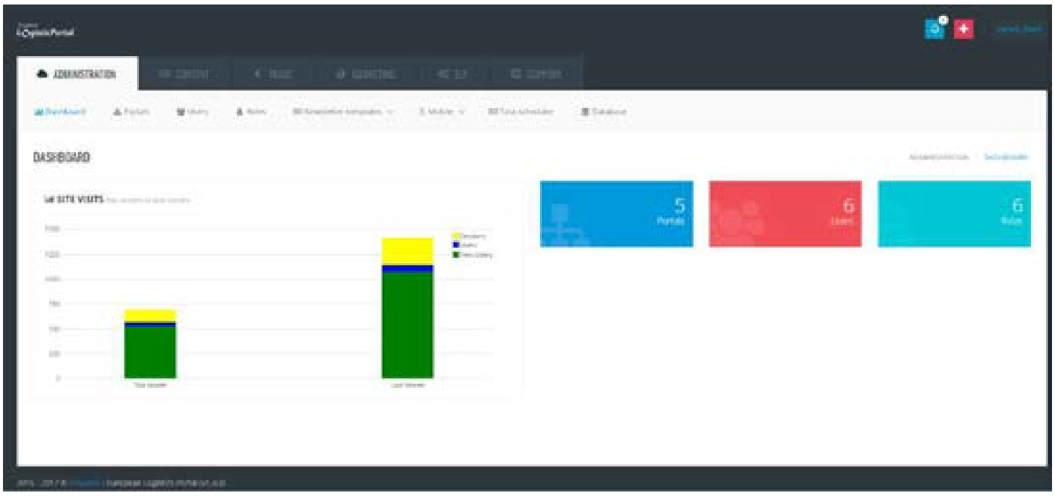

Fig. 4
Logistics portal Eurologport.eu application
Source: Authors, based on the final report of the project

4.4. Web Portals and Mobile Applications

Graphic designs and their functionality were implemented in the content management system. The result was implemented on the following websites: www.eurologport.eu, www.eurologport.cz, www.eurologport.sk, www.eurologport.hu and www.eurologport.pl. Webpages were successfully tuned and started in trial first, and then, in routine operation according to the project planned schedule.
The information system design has represented the result of all the project solution. A software solution for the content management system has been created to enable safe and seamless data exchange between national portals involved in the franchise project and the CELP - Central European Logistics Portal, including an operational and functional native

mobile application for the iOS and Android mobile operating systems. Implemented national information portals in the web environment represent other results.
The ultimate objective of the researchers was to develop such an information system that is capable of further research and development, and it is possible to respond to it, based on a modular structure in order to allow for its users, logistics, transport, forwarding and other companies to use it. It is brought to them in the form of validated up-to-date information from the field of logistics, and possibly, resulting cost savings based on logistics processes management arising from the correct input information (Buková *et al.,* 2016), (Chan, 2014), (Conger, 2012).
During solving the project, the research team worked according to the best practices used for other solved projects. Analytical and programming documentation has been stored in the cloud or on researchers' servers (McQuaid, 2015), (Sýkorová and Čverhová, 2011).

5. Conclusion

Works on the whole project were divided into three successively phases. The first phase included processing the initial analyzes for the correct definition of the designed logistics information portal final structure and related information system structures including its modular setting. At this phase, the solution involved parallel works of several groups of researchers, especially analysts, programmers, examiners, consultants and project manager. The editorial system architecture design and individual function models of the information system special modules were the most important results of this phase.
The objective of the second phase was to implement the web portal into the content management system and implement all the individual national portals into the web environment based on analyzes from the previous phase and based on the comprehensive detailed analysis of national environments. These environments mainly solved the selection of a suitable partner for the national portal operation, the content management system communication range between the national portal and the transnational CELP environment.
The CELP information portal design implemented and tested as well as its national version in the national web environments of the Czech Republic, the Slovak Republic, Hungary and Poland represented the results of this phase.
The objectives of the final phase project participation were the following activities: to analyze the mobile environment for effective work on programming of mobile application, the design of mobile applications for Android and iOS operating systems, the restriction analysis of the system possible connection to the national registers, the development of connection including trial operation with the selected Czech portal. Based on this testing, a particular solution to connect other national registers was prepared. During the project participation, the research team worked according to the best practices used for other solved projects. The analytical works were based mainly on data collection, data modeling, the system object-oriented design and the proposed system modular structure. All the planned objectives and project results have been successfully fulfilled.

Acknowledgment

Acknowledgments include the Czech Republic, from whose budget this research project was co-financed throughout its solution. It also includes acknowledging the entire team of researchers for responsible and professional approach to research and development tasks and for opponents and members of the Opponent Commission to participate in project evaluation.

The paper is published in the framework of the LF - EUREKA CZ - LF15010 - "CELP - Logistics Portal for Central Europe".

IMPACT OF CRM ON THE QUALITY OF THE NEW POSTAL SERVICE - BH POSTEXPRESS

Amel Kosovac[1], Azra Ferizović[2], Abidin Deljanin[3]
[1,2,3] University of Sarajevo, Faculty of Traffic and Communication, Sarajevo, Bosnia and Herzegovina

Abstract: Modern postal companies cover a complex area that is intertwined with communications, logistics and advertising, and its process activities consist of three phases: the process of communication, logistics processes and advertising processes. New concepts of decision support in decision-making postal-logistic traffic rely mainly on useful information and the application of various IT technologies (BI, SCM warehouses, ERP, CRM) used to avoid and predict unexpected events that are rapidly occurring on a dynamic postal market. Today's business cycles of modern postal operators are compressed, faster, contain more data, and a faster and more efficient decision-making system that represents the real competitive advantage of postal companies. Competent organizations aware that performance management processes and relevant flows of data, information and knowledge have a decisive impact on their success. The focus on postal service users, based on quality and timely customer service, is the basis for successful postal operators. The paper analyzes the impact of the call center as CRM tool on the quality of providing new postal service - BH PostExpress in PE BH POST Sarajevo.

Keywords: CRM -Customer Relationship Management), call center, BH PostExpress, customer satisfaction, business performance, quality.

1. Introduction

Under the conditions of deregulation and full liberalization of postal traffic, public postal operators are confronted with competition every day, which in every way tries to take as many services as traditionally provided by public postal operators.. In order to survive in the open postal market and respond to these challenges, public postal operators pay close attention to the quality of service delivery and the application of modern technologies to new and value-added services.The World Postal Union's Congresses of the past years pay special attention to the quality of services provided by postal operators. The quality of postal traffic is reflected in the quality of postal services. In order for the postal operators to provide quality service to their users they must properly plan, design and build the postal network to ensure the planned traffic capability. In this paper, we have come to know the essence of customer relationship management with the aim of improving the quality of postal services, all of which are based on the example of the call center business on the new postal service BH PostExpress in PE BH POŠTA.

Today, when markets become saturated, and competition is getting bigger and more serious, it is no longer easy to attract and even less retain users. Greater customer care and the development of long-term personalized relationships become the cornerstones of every business. The concept - "customer care" becomes the only correct solution if public postal operators want to survive and succeed on the postal market.

Customer relationship management takes more significant place in the company's business strategies, especially with postal operators where it is necessary to continuously communicate and share information with its users. The contemporary business of modern and successful companies is based on the Customer Relationship Management (CRM) concept. This is the concept of a newer date, which completely changes the current approach to customers, more focusing on them and their needs that are nowadays individualized, as opposed to far-reaching focus on service and sales. Technological innovations and especially development of information technologies and computer technologies, have led to changes in the lives of individuals, the world around us, and so on the business environment, which has caused changes in the way business transactions are performed and the customer's position change in the value chain.

The problem of developing and maintaining long-term relationships with consumers CRM analyzes deeper, taking into account all the internal and external elements that touch this problem. The purpose of the CRM concept is to enable a more efficient implementation of the set business strategy and goals through the consideration of consumer needs. CRM as a concept represents the alignment of business strategies, organization structures, behavior, collection, processing and use of information, in order to meet their needs at all touch points with customers and achieve business profit of company. This strategy, which puts the customer into the center of business events and activities, solves the institution's doubts about who their clients are, and which are the most valuable ones. In order to improve the quality of postal services, PE BH POŠTA introduces the new postal service BH PostExpress (fast mail). This is an added value service that enables the transfer of consignments to legal entities and individuals in the territory of Bosnia and Herzegovina.

2. A General Model for Quality of Postal Services

If the postal operator is able to properly define the quality of its services, it will be able to combine its economic interest and the expressed and undisputed customer requirements for a certain degree of quality. A good level of quality of postal services directly influences pricing policy, increases the interest of users for further use of services, or increases business performance of postal operators. Post Operators must properly plan, design, build postal networks and continually innovate their offer with new services so their offerings can meet the needs of their customers. The quality of postal

[1] Corresponding author: amel.kosovac@fsk.unsa.ba

services is seen as a common effect of several characteristics that all together determine the degree of user satisfaction. In order to adapt to the needs and demands of its users, postal service providers should look at quality first and foremost from the customer's point of view..

Postal operators in an increasingly liberalized market are striving to provide an acceptable level of postal network quality for users at minimal cost, and in that case achieve the maximum possible financial impact, taking into account the more effective strategic planning, design, construction and maintenance of the postal network. The user's quality-related observations point to the effects rather than the causes. That is why the postal operator aims to strike a balance between the quality of services which users needs and the quality of services whose strategic planning, design, implementation and maintenance needs to be the most economical.

Measures leading to quality improvement can be classified as:

- Availability of postal units and means;
- Availability of capacity;
- Efficiency in the connection process;
- Continuous innovation and introduction of new service and value added services;
- Knowledge of each level of organization for quality management;
- Innovative program to achieve the anticipated quality of services;
- Strengthen internal marketing within the company.

The main objective of the postal service quality model is to provide a detailed description of the characteristics and parameters related to the quality of service from the point of view of operator, user and manufacturer of necessary service equipment. This model should combine features and service parameters related to the development, design and exploitation.

The general model of quality of postal services can make:

- Provision of the postal operator with the necessary technical equipment or the ability to rent and install certain technical equipment that provides the desired type of service;
- Automation of equipment on which the user can handle independently to achieve the desired service;
- Availability of the service - the ability of the operator to enable the provision of the service at any time required by the user;
- Reliability of postal service delivery - probability that there will be no interruption during the service period that could permanently terminate the requested service;
- Incompatibility of service - users' resistance to the interference that occurs when connection is established.

2.1. Quality as a Survival Factor in the Postal Service Market

The need to reduce inventory in the overall supply chain and reduce delays in the process of distributing material goods directly affects the increasing complexity of postal traffic. New challenges such as globalization, liberalization and privatization of the postal sector, the necessity of incorporating into European integration processes, and demands for high-quality traffic services create a new ambiance of postal operators' business, which requires innovative approaches to business in order to strengthen the postal operator's position on the liberalized and open postal market. Postal operators in modern society must necessarily improve their efficiency and competitiveness by simultaneously reducing their resources to survive in the market of modern technologies.

Postal operators depend and will increasingly depend on the integrity, reliability, security and applicability of information systems and processes and data in the organization as a whole. The information gained from the available data of postal system through Data mining is the basis for guiding both the reactive and proactive future behavior of the postal operator. Therefore Postal operators have to listen every day to customers and adapt their services and operations to their needs and requirements, not neglecting their public service role as well. The focus on postal service users, based on quality and timely customer service, is the basis for successful postal operator operations. The requirements for quality of postal services include a hierarchical organization processes based on the user principles that relate to (accountability, security, planning, accuracy and reliability, information, availability of mobile capacity, after-sales service), followed by the use of high technology transport equipment supply chain as well as a postal process management system with the use of modern information technologies based on management practices.

Today's business cycles of modern postal operators are compressed, faster, contain more data and a faster and more quality decision-making system that represents the real competitive advantage of postal companies. Traditional postal services can no longer provide the prosperity of this system, but new services and new markets with new technical and technological achievements are needed. Postal operators must be paid to particular attention to the quality of the services they provide. Under the conditions of unfair competition to which postal systems are exposed, improvement of quality is set as a basic competitive advantage. That is why the European Union has mandated the standards of universal postal services that the public operators of other European countries follow and apply depending on the level of their development and capabilities.

2.2. Quality in the Strategies of the World Pact's Congress

Over the last twenty years, various factors have influenced the postal sector to re-examine its role in the communications market. The combined action of direct and indirect competition, privatization, liberalization, separation of operator and regulatory functions, user demand for better and more reliable services, and new technologies, convinced postal sectors to change their operational and financial strategy to remain competitive.
Developed European postal operators rapidly reach enviable standards in upgrading postal services as well as redesigning business processes by applying business intelligence to improve business efficiency and survival on a liberalized postal market. The application of business intelligence does not only include the full range of postal services, but also the framework for all the management, logistical processes that take place within the operator. The focus on postal service users, based on quality and timely customer service, is the basis for successful postal operator operations.
One of the elementary indicators of the economy's impact on postal activity is the level of consumption that is expressed in the number of postal shipment per capita per year. Analyzing competition on the postal market, it has been shown that the basic strength of postal sector is in its ability to monitor service and quality control "from the beginning to the end" based on powerful information systems and the application of their technologies.
The Universal Postal Union has defined the basic principles that a postal operator should apply if it wants to successfully counter market competition:

- Get acquainted with the market in which it operates (user needs, competition, new service, etc.);
- Meet customer needs in all aspects and adopt the concept of total quality for all offered products and services;
- Automate the technology and service management offered on the market.

The main goals of the Strategy adopted at the XXV Universal Postal Congress are:

- Improve the interoperability of the international postal network;
- Provide technical knowledge and expertise in the postal sector;
- Promote Innovative Products and Services;
- Promote sustainable postal sector development.

Postal Traffic has so far been concerned with quality through the assessment of the functioning of postal traffic and through improving the quality by changing the existing state of the organization in order to increase the effectiveness and efficiency of all activities and processes, in order to gain additional benefits for the organization and for its users. However, in the new business environment of postal sector, which comes with deregulation and liberalization, when it enters the process of continuous changes, a quality system must be established by establishing and maintaining the state of change in organizational structure, procedures, key and business processes and resources for quality management.
That is why for the postal sector the ultimate goal is to approach the Total Quality Management-TQM, which represents a broadly standardized, contemporary management approach for achieving quality goals. TQM is the process of system, accurate, complete and continuous changes in the management of the entire company with 218 quality aids in the direction of continuous improvement of overall business. TQM is based on ISO 9000 Series standards and represents a permanent and infinite process of improving overall performance across the company..
The basic principles of TQM can be expressed through the following processes:

- Continuous fulfillment of customer requirements to achieve its satisfaction;
- Continuously improving the overall performance of the postal organization;
- Continuous growth and development of postal organization with the satisfaction of all interested parties (owners, employees, society).

In order to provide quality in the company, it is necessary to make certain procedures and documentation. Acceptance solutions (guidelines, guidelines, models) for quality management through the quality system were provided by the ISO 9000 series. The quality system in postal traffic implies the determination of procedures to determine the requirements for characteristics of all service delivery processes, including marketing processes, service delivery as well as feedback that contribute to improving the quality of postal services. This also includes evaluations of the service performed by the user and the quality control of the implementation and efficiency of all elements of the quality system.

3. Competitive Benefits of Using CRM Methods Relating to Clients

Successful organizations know that performance management processes and relevant streams of data, information and knowledge have a decisive impact on their success. Such organizations note that performance management knowledge is the one that drives business and the most important knowledge of the organization.
CRM (Customer Relatioship Management) represents the integration of all business processes and technologies used to communicate with existing and potential customers and business partners across all available communication channels. CRM can be seen as a wider business strategy designed to reduce costs and increase profitability and efficiency by creating total loyalties for users. It represents every possible aspect of company interaction with its users, whether it is a sale or service. The basic objective of this business strategy is to personalize business with each user individually.
This means that every user will have a separate treatment and offer of those services that are most needed at the given time and which will only apply to him.

The beneficiaries have the opportunity to have available suppliers at all times of the day and at night, choosing and buying products or services, making inquiries and making payments without any direct physical contact, leaving their workplace or home. On the other hand service providers have the ability to provide twenty-four-hour online customer-tailored offerings that are available at any time, in every location, with consummate computer equipment.
The basic philosophy of the CRM concept in postal traffic is based on the claim that if a company has certain information about its user (what it wants, what kind of postal service it requires, what needs it meets, etc.) sales of such postal service will be much more successful and the user will be more satisfied. The most important CRM factor is timely and useful information.
This strategy, which puts the customer into the center of business events and activities, solves the institution's doubts about who their clients are, and which are the most valuable ones. Market and consumer access, marketing methods can no longer be implemented without the use of information-communication technologies, leading to significant changes in marketing, planning, strategy development and development. The CRM concept is a set of institution options, approach methodologies, and purposeful application of technology, enabling the commercial functioning of institutions. Through information-communication technologies, and especially the Internet, direct connection is made possible through the use of computer networks, supply and demand.
Using the CRM concept has multiple goals:

- detailed customer identification;
- segmentation of clients according to their needs and potential values for the institution;
- establishing quality and sustainable interaction with clients;
- creating an organization oriented towards the client;
- customizing products and services to customers and their needs.

The introduction of CRM does not represent the technological equipment and implementation of technical logistics in financial institutions, but changes in approach and thinking of all employees from top ranked managers to executive operatives. Today, this is the biggest problem and the key to the success of those who have decided to apply this concept. Customer Relatioship Management is a marketing process (marketing one by one) that directs the business orientation of an enterprise towards an individual consumer. Basically the CRM concept lies in a simple idea, which is "differently treated different consumers". The efficiency of the CRM process, which needs to be integrated through marketing, sales and through consumer relationship, implies:

- identification of factors that contribute to a successful relationship with consumers;
- developing practices in consumer relations;
- developing a process that will benefit consumers;
- formulation of issues that would best assist the solution of potential consumer problems;
- recommendation of solutions for consumers who have a complaint about the product / service;
- track sales as well as consumer support.

3.1. The Impact of CRM on Customer Satisfaction, Loyalty and Business Performance of the Postal Operator

An important reason for CRM (Customer Relationship Management) is that it enhances business performance by improving customer satisfaction and increasing customer loyalty, as shown in Figure 1. There is an appropriate logic of the model called the "satisfaction-profit chain ".

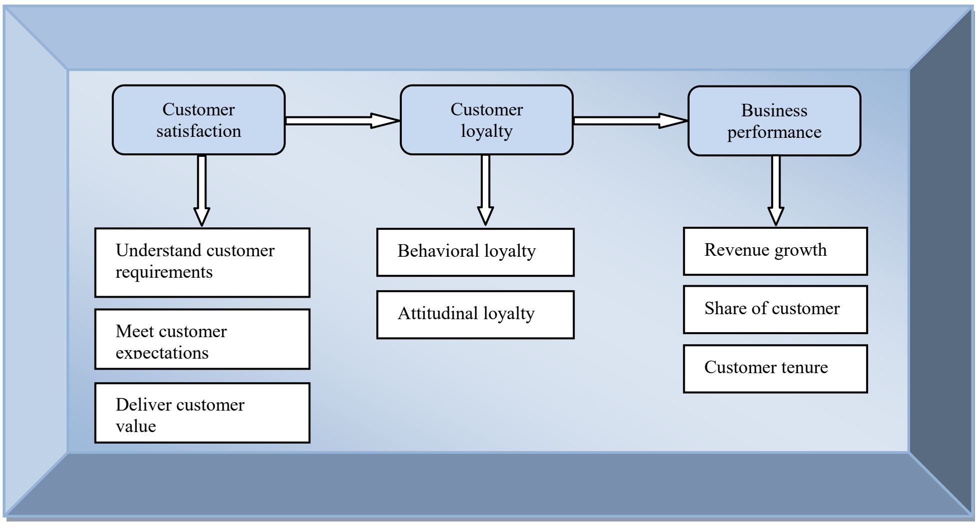

Fig.1.
The satisfaction– profit chain
Source: (Buttle, 2008), page 68-72

Satisfaction increases because customer insight allows companies to understand their customers better, and create improved customer value propositions and better customer experiences. As customer satisfaction rises, so does customer intention to repurchase. This in turn influences actual purchasing behaviour, which has an impact on business performance. We'll examine the variables and linkages between them. First we'll define the major variables of customer satisfaction, customer loyalty and business performance.

3.2. Customer Satisfaction

Customer satisfaction has been the subject of considerable research, and has been defined and measured in many ways. We define customer satisfaction as follows:
Customer satisfaction is the customer's fulfilment response to a customer experience, or some part thereof. Customer satisfaction is a pleasurable fulfilment response. Dissatisfaction is an unpleasurable fulfilment response. The 'experience, or some part thereof' component of the definition suggests that the satisfaction evaluation can be directed at any or all elements of the customer's experience. This can include product, service, process and any other components of the customer experience. The most common way of quantifying satisfaction is to compare the customer's perception of an experience, or some part of it, with their expectations. This is known as the expectations–disconfirmation model of customer satisfaction. This model suggests that if customers perceive their expectations to be met, they are satisfied. If their expectations are underperformed, this is negative disconfirmation and they will be dissatisfied. Positive disconfirmation occurs when perception exceeds expectation. The customer might be pleasantly surprised or even delighted. This model assumes that customers have expectations, and that they are able to judge performance. A customer satisfaction paradox has been identified by expectations–disconfirmation researchers. At times customers ' expectations may be met but the customer is still not satisfied.
This happens when the customer's expectations are low. 'I was expecting a shipment late and late. I'm unhappy!'
Many companies research customer requirements and expectations to find out what is important for customers, and then measure customers ' perceptions of their performance compared to the performance of competitors.

3.3. Customer Loyalty

Customer loyalty has also been the subject of considerable research. There are two major approaches to defining and measuring loyalty, one based on behaviour, the other on attitude.
Behavioural loyalty is measured by reference to customer purchasing behaviour. Loyalty is expressed in continued patronage and buying. There are two behavioural aspects to loyalty. First, is the customer still active? Secondly, have we maintained our share of customer spending?
In portfolio purchasing environments, where customers buy products and services from a number of more-or-less equal suppliers, the share of customer spending question is more important. Many direct marketing companies use RFM measures of behavioural loyalty. The most loyal are those who have high scores on the three behavioural variables: recency of purchases (R), frequency of purchases (F) and monetary value of purchases (M). The variables are measured as follows:

- R - time elapsed since last purchase;
- F - number of purchases in a given time period;
- M - monetary value of purchases in a given time period.

Attitudinal loyalty is measured by reference to components of attitude such as beliefs, feelings and purchasing intention. Those customers who have a stronger preference for, involvement in, or commitment to a supplier are the more loyal in attitudinal terms. Recently, researchers have combined both views into comprehensive models of customer loyalty. The best known is Dick and Basu's model, as shown in Figure 2.
These authors identify four forms of loyalty, according to relative attitudinal strength and repeat purchase behaviour. 'Loyals' are those who have high levels of repeat buying and a strong relative attitude. 'Spurious loyals' have high levels of repeat purchase but weak relative attitude. Their repeat purchasing can be explained by inertia, high switching costs or indifference. Latent loyalty exists when a strong relative attitude is not accompanied by repeat buying. This might be evidence of weakness in the company's distribution strategy, the product or service not being available when and where customers want. From a practical point of view, the behavioural definition of loyalty is attractive because sales and profits derive from actions not attitudes.
However, taking the trouble to understand the causes of weak or negative attitudes in customers can help companies identify barriers to purchase. It is equally true that knowledge of strong or positive attitudes can help companies understand the causes of competitor-resistant commitment. However, it is not clear from the Dick and Basu model whether attitude precedes behaviour or behaviour precedes attitude. Researchers generally accept that causation is circular rather unidirectional. In other words, attitudes influence behaviour, and behaviour influences attitude.

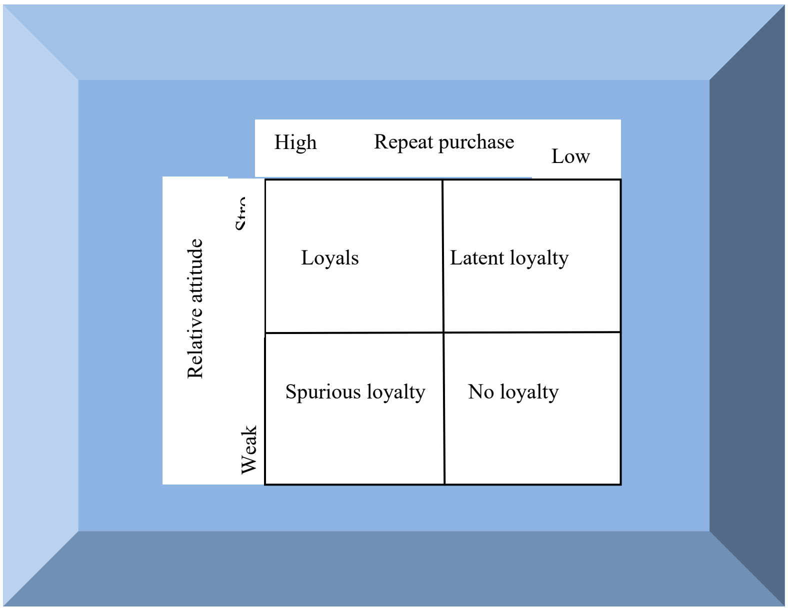

Fig. 2.
Two-dimensional model of customer loyalty
Source: (Buttle, 2008), page 68-72

3.4. Business Performance

Business performance can be measured in many ways. The recent trend has been away from simple short-term financial measures such as quarterly profit or earnings per share. Leading companies are moving towards a more rounded set of performance indicators, such as represented by the balanced scorecard. The balanced scorecard employs four sets of linked key performance indicators (KPI): financial, customer, process and learning and growth. The implied connection between these indicators is that people (learning and growth) do things (process) for customers (customer) that have effects on business performance (financial). Customer-related KPIs that can be used to evaluate business performance following a CRM implementation include: customer satisfaction levels, customer retention rates, customer acquisition costs, number of new customers acquired, average customer tenure, customer loyalty (behavioural or attitudinal), sales per customer, revenue growth, market share and share of customer (wallet). The balanced scorecard is highly adaptable to CRM contexts. Companies need to ask the following questions. What customer outcomes drive our financial performance? What process outcomes drive our customer performance? What learning and growth outcomes drive our process performance? The satisfaction–profit chain suggests that the customer outcomes of satisfaction and loyalty are important drivers of business performance.
Share of customer (share of wallet or SOW) is a popular measure of CRM performance. If your company makes a strategic CRM decision to serve a particular market or customer segment, it will be keen to measure and grow its share of the chosen customers ' spending. As indicated in Figure 2.8 , share of customer focuses on winning a greater share of targeted customers ' or segments' spending, rather than market share.

4. Packet-Courier Service BH POST EXPRESS

In order to improve the quality of postal services, PE BH POŠTA introduces the new postal service BH PostExpress (fast mail). It is an added value service that enables the transfer of consignments for legal and natural persons in the territory of Bosnia and Herzegovina.
The delivery of BH PostExpress services is transmitted from the reception site to the delivery time within the deadlines depending on the BH PostExpress type service for a fee, determined by the BH PostExpress Pricelist in the internal traffic. Consignments can be sent as individual, total consignments of a total mass of up to 50 kilograms and as a pallet of a maximum weight of 500 kilograms. Shipment may be with or without a marked value, and the maximum marked shipment value may be up to 5,000 BAM. The price of the service depends on the weight of the shipment and the time it will be delivered. A mass of up to 10 pounds and delivery on the same day costs 12 BAM, while it will cost 8 BAM within two days. A delivery of 150 to 200 kilograms, if delivered on the same day until 12 o'clock, would cost 80 BAM while within two days the cost of delivery would cost 65 BAM.
Users across the territory of BiH have four types of new service transfer available:

- today delivered, today handed down;
- today delivered, today delivered until 18 o'clock;
- today delivered, tomorrow delivered; and
- (D + 2) today handed over, delivered for two days.

The reception of BH PostExpress consignments is made on a call at the address of the user, or in the business premises of the sender and at the mail counter, every working day (including Saturday), from 08:00 to 18:00 on the call center number 1417.

4.1. Implementation of the Call Center in the BH Post Express Parcel/Courier Service

The Contact Center is a business system that combines voice and electronic communication with users, and modern data processing technology, enabling:

- adequate customer support;
- support for marketing activities;
- improvement, automation and increased sales of services;
- successful management of contacts with users;
- improve overall image of the company.

Physically, this is the place where a group of agents / operators manages a large number of incoming and outgoing calls/contacts with users, by phone, web site, email, etc. and routing requests to the Mail Centers through an appropriate application solution. Contact Center PE BH Post d.o.o. Sarajevo is a central place for customer care, through activities and activities that imply:

- provide relevant information on the services of PE BH POST in internal and international traffic;
- resolving reception, dispatch and delivery of mail and other services;
- receive announcements for BH Post express, ems and tg services.

The Contact Center is to be seen as an independent project that will enable business processes and tools to enhance Customer Relationship Management (CRM) and Public Relations (PR).
Implementation of the BH POST EXPRESS Contact Center is also an innovative approach in terms of increasing customer loyalty and implies an effort to design a business system that will enable unified and decisively defined technological delivery procedures for "BHPost Express", with simultaneous control and reporting, in order to redefine and correction of possible irregularities management.
The introduction of new BH POST EXPRESS services does not depend on the implementation of the Integrated Contact Center system, but this service uses the resources of the Contact Center and is an integral part of the order / announcement management, monitoring of consignments and providing information and complaints. The task is to ensure the same and sufficient quality of communication with the users, through the unified ways of answering the operator, and a precisely defined distribution information procedure in the open work order.
In order to achieve savings and optimize service delivery processes, a well-organized Contact Center should have been enabled:

- Easy ordering services;
- Receipt and delivery of consignments agreed on a precise location and the responsible user.

The implementation of this solution implies activities of integration of business / technology processes that will enable the monitoring of each individual shipment, from the moment of the shipment notification, to the physical delivery to the recipient. It is important to define the procedures and ways of acting agents in the Contact Center, and dispatchers at the Post Centers and other participants in the BH POST EXPRESS service process technology. Also, the BH POST EXPRESS Application Center solution has an integral unit / module integrated GPS tracking system .Global Positioning System), which enables proper route design and routing of vehicles, and optimizes and reduces the cost of fuel.

4.2. The Organizational Chart and Human Resources of the Contact Center in the BH Post Express Parcel/Courier Service

The Figure displays the Contact Center BH POST EXPRESS, which is an integral part of the Corporate Contact Center of PE BH POŠTA d.o.o. Sarajevo offers unified services such as BH POST EXPRESS, EMS and service telegrams, real-time process monitoring, control of delivery deadlines and stable point detection in the system.
BH POST EXPRESS parcel / courier services segments in the Contact Center:

- Contact CENTER BH POST EXPRESS - Centralized with operators, located at GPC, connected to the number 1417.
- DISPERSERS AND DISTRIBUTORS - Dispatcher, Dispatcher system and other technology vendors, as a BH POST EXPRESS service segment, by Mail Centers.

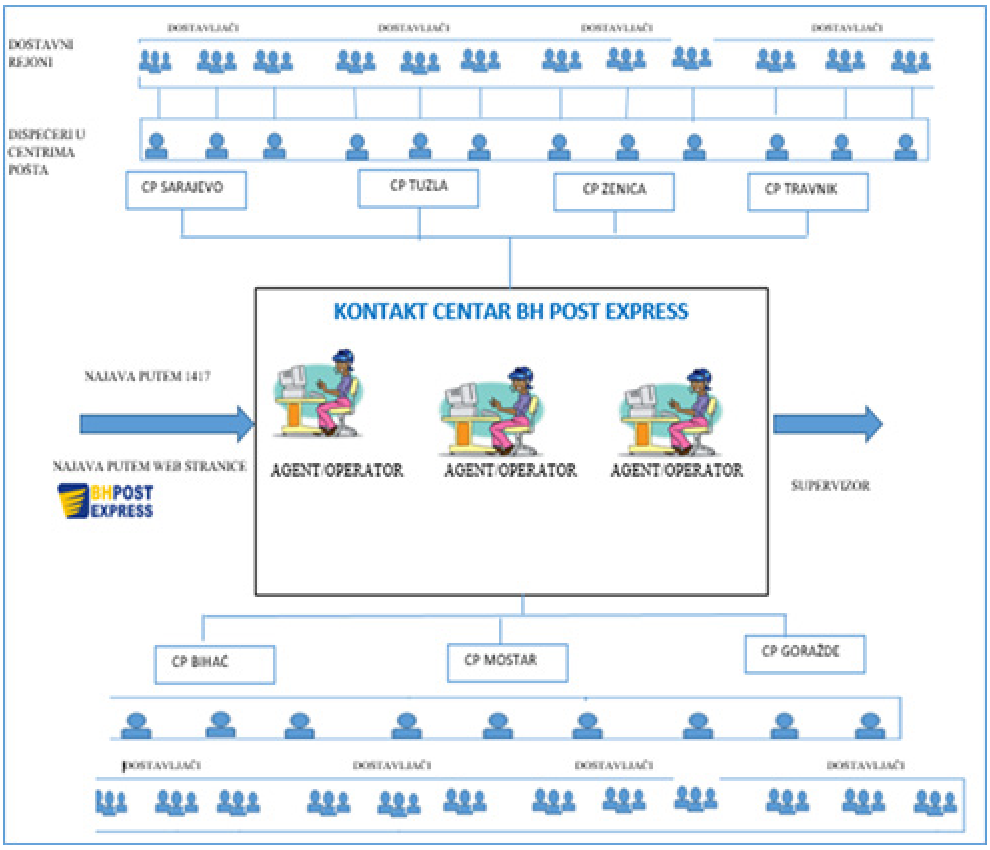

Fig. 3.
Organizational Scheme Contact Center BH POST EXPRESS
Source: BH Post Express distribution support in the area of Bosnia and Herzegovina, PE BH POST Sarajevo.

This approach to the Contact Center is an innovative approach as it enables full satisfaction of customer needs while providing unambiguous and precise procedures for dealing with BHPOST EXPRESS shipments, phone logs, reception at the address and counter and delivery thereof, simultaneous tracking of consignments, complete control and timeliness and quality control. Also, this approach enables optimal delivery and pickup processes, routing delivery vehicles through the integration of GPS systems into the Contact Center system.

AGENTS/OPERATORS – Of contact Center BH Post Express is located in GPC Sarajevo and has full capacity of three (3) agents. Computer Agents have BH POST EXPRESS agent applications and are applicatively linked to dispatchers in all Mail Centers.

DISPATCH CENTERS IN THE POINTS CENTERS – The second level or operator that receives the work orders / tags from the GPC Contact Center agents, and is organized by the couriers on the field. The organization of the Dispatch Center, Delivery and Postpaid Recipients is integrated with each Mailing Center for the part of the postal network for which the Post Office has jurisdiction. The BH POST EXPRESS Contact Center would communicate directly with users, avoiding the possibility of congestion and rejection of customer calls due to the small capacity of the Contact Information Center and Complaints Center at 1312.

EXSPERT IN GENERAL DIRECT OF POSTAL OPERATOR – The person who supervises the whole system and communicates with the other two postal operators. This person is in charge of all contacts and activities that require alignment with the other two postal operators and a person who knows the service of BH POST EXPRESS in all technological phases.

In addition to human capacities, in the work of the BH POST EXPRESS Contact Center, particular attention should be paid to the way of communication with users, the rules of unified behavioral procedures and the work of the Contact Center to avoid some of the most common errors in the Contact Center:

- the user waits for a long time on the line until the next operator is free;
- "Switching" users from one operator to another;
- low employee motivation.

4.3. Customer Communication Channels - Receipt of Orders

Contact with customers takes place through two communication channels:

- Telephone number 1417;
- Via contact form on the web page.

Reception of BH POSTA EXPRESS postal shipment can be made by calling at the address of the user or in the office of the sender. The BH POST EXPRESS Contact Center is announcing the announcement of the BH POST EXPRESS postal shipment take over from 8:00 am to 6:00 pm by phone number 1417. The reception of these postal shipments and the announcement of postal shipment relates only to the narrower areas of the towns of Bihać, Mostar, Travnik, Tuzla, Sarajevo and Zenica, including the larger users in the Sarajevo Post Office, and the headquarters of the Municipality of Ilidža, Hadžići, Ilijaša and Vogošće.

4.3.1. ANNOUNCEMENT VIA CALL ON 1417

Agent of Contact Centers BH POST EXPRESS receives a telephone announcement of the receipt of BH POST EXPRESS postal shipment at the address of the user or in the business office by entering the sender's information in the "BH POST EXPRESS Posting Diary" message via the Contact Center via Phone 1417 "according to the text of the form.

After filling out all the necessary information, the received work order/address is applied automatically and automatically to the dispatch center at the Post Office for which the announcement relates. Dispatchers in the Post Center perform the delivery organization in accordance with the best practice of optimizing work processes.

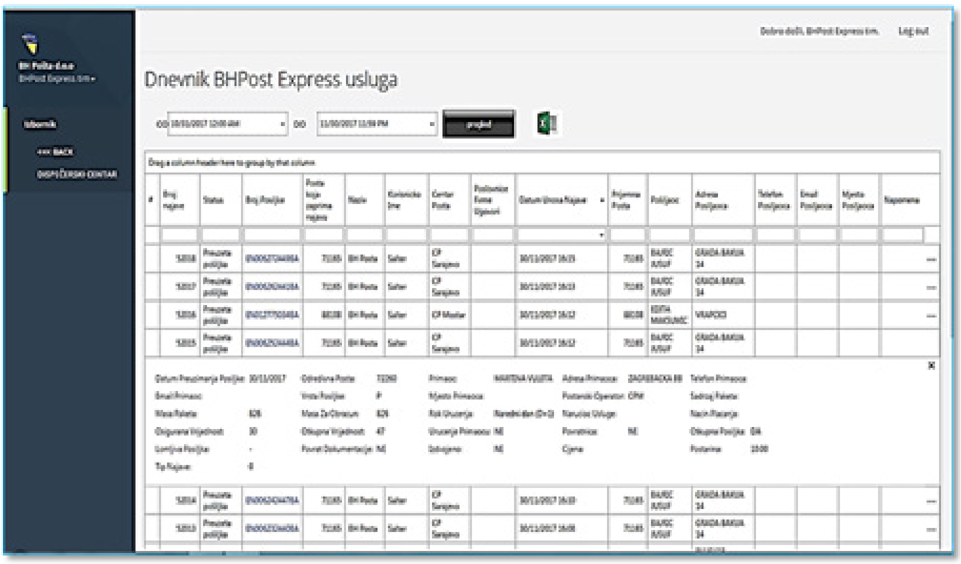

Fig. 4.
BH POST EXPRESS service diary
Source: (BH Posta, 2018)

4.3.2. ANNOUNCEMENT VIA CONTACT FORMS ON WEB PAGES

If the announcement is made through a web application, Agent of the BH POST EXPRESS contact center must verify the authenticity of the entered data by confirming the validity of the job order by calling the user and confirming the credibility of the entered data via the contact form. Contact form or order form BH POST EXPRESS through a website, will be defined in accordance with the technological solutions of the service, with all the necessary inputs for the service to be executed. Also, a form of contact (online calculator) in the form of a virtual assistant must have such features to maximize the user's convenience and to assist him in choosing the appropriate service (dimensions, speeds, delivery to the address etc.). Selection system, gets the ultimate price for that type of service you have chosen.

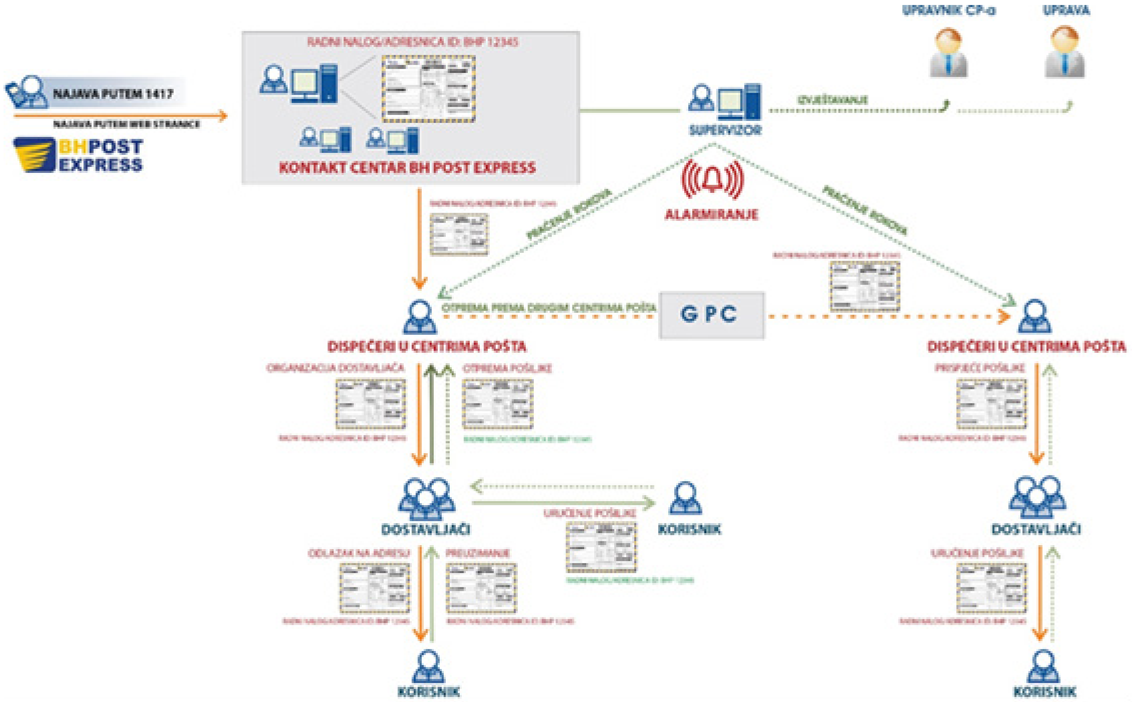

Fig. 5.
Information flow of Contact Centar and treatment of all participants in the service delivery process
Source: (PE BH POST, 2018)

Number 1417 is geographically linked to the Center Post Office, and it is necessary to make the necessary activities that will routed calls to the BH POST EXPRESS Contact Center at GPC. The intention is to have the complete platform of the Contact Center on VoIP technology, which would reduce costs and improve the routing capabilities of the Contact Center.

5. Conclusion

Quality in postal traffic today represents the postal operator's image, a powerful weapon against competition and a means to ensure progress and survival on a liberalized postal market. Quality is the right answer to the growing demands of users of products, goods and services. By ensuring the quality, each company ensures the satisfaction of the users, but also their own satisfaction, and the satisfaction of their employees, suppliers, and thus the entire community.
New challenges such as globalization, liberalization and privatization of the postal sector, the necessity of incorporating into European integration processes, and demands for high-quality traffic services create a new ambiance of postal operators' business, which requires innovative approaches to business in order to strengthen the postal operator's position on the liberalized and open postal market . Postal service users are increasingly demanding because they have a greater choice of a more favorable operator. By measuring customer satisfaction, we come to extremely valuable business information that enables us to plan and implement many important business moves. Knowing the satisfaction of the users, postal operators can react before they lose the market and before some weaknesses are reflected in their business. All these are indicators for the rapid improvement of the quality of postal services.
Quality should not be imagined as a morality - quality of postal services is a need that demands: quality planning, quality control, quality assurance and quality improvement to achieve the best quality of postal services.
In order to improve the quality of postal services with the concept of CRM, PE BH POŠTA introduces the new BH POST EXPRESS packet - courier service. BH POST EXPRESS is a value added service that enables the transfer of consignments for legal entities and individuals in the territory of Bosnia and Herzegovina. The BH Post Express services postal shipment are transmitted from the place of reception to the place of delivery within the deadlines depending on the type of BH Post Express service for the fee, which is determined by the BH Post Express In-Service Internal Price list. The reception of BH PostExpress postal shipment is made on a call at the address of the user, or in the business premises of the sender and at the mail counter, every working day (including Saturday), from 08:00 to 18:00 on the call center number 1417. Packet/courier service BH POST EXPRESS uses the resources of the Contact Center and is an integral part of the order/announcement management, tracking of consignments and providing information and reclamation. The task is to ensure the same and sufficient quality of communication with the users, through the unified ways of responding to the call operator, as well as the precisely defined information distribution procedures in the open work order, which directly influences the increase of the satisfaction and loyalty of the user PE BH POŠTE.

MODELING FRAMEWORK FOR LAST-MILE LOGISTICS SERVICES

Alexia Irakleous[1]
[1]University of the Aegean, Department of Shipping and Trade, 2a Korai Street, 82132 Chios, Greece

Abstract: Last-mile delivery services are considered a critical part for e-shopping activity. Especially in urban areas rigorous planning is required by logistics service providers, due to uncertain demand, traffic conditions and geographical particularities. To this end, the main purpose of this paper is to measure consumers' most recent e-shopping experience to understand, study and evaluate consumer behavior towards delivery service attributes. A modeling framework is developed that includes consumers' characteristics, household characteristics, e-shopping characteristics, delivery service attributes and e-shopping motive. A survey was conducted in the city of Athens (Greece) and data were collected from 140 consumers who have a prior experience in online shopping and their replies were used to test the research model. The research findings pointed out that delivery service attributes are depending on the product type and value chosen as well as e-shop origin. E-shopping is mostly preferred by consumers to fulfil their utilitarian motives, and then to feel satisfaction. The most significant delivery service attributes were time of delivery, electronic notifications, delivery cost and return label. The results of this research can be used to the effective design and optimization of last-mile delivery service.

Keywords: last mile, e-shopping, delivery service attributes, consumer shopping behavior.

1. Introduction

The increasing trend of e-commerce has induced the transportation of small and fragmented shipments to be delivered at a specific point, and time as well as with additional service features based on consumer's requests. This type of goods' movement, from a transportation hub to a final destination which is either at consumers' home address or at a pick-up point, is called 'last-mile' delivery. Last-mile is the most complicated segment of the transport chain, as it involves adapted processes depending on geographical issues, cultures and habits of e-shoppers. Further to this, the share of costs related to the last mile, as part of the total transport costs, may range from 13% up to 75% of the total supply chain (Gevaers et al., 2009). Although this type of transport is traditionally performed by postal operators who distribute mail and other small shipments to people's home address, e-commerce generated changes in the patterns of last-mile deliveries in order to meet the so-called 'last mile challenge' of getting online orders to people with different needs in a specific geographical area with the most efficient way.

The importance of e-commerce and delivery services is one of the top five priorities of the European Union in order to promote e-commerce among European countries (Ecommerce Europe, 2016). Therefore, one of the most important categories of good practices within the context of e-commerce concerns the improvement of delivery service solutions in order to rationalize the last mile delivery. To this end online shoppers' attitudes and preferences should be the object of additional investigation to integrate their impact on shaping last mile operations. Understanding consumers' needs can be the key differentiator, for planning an efficient and sustainable last-mile delivery system not only for providers who have to organize transportation and retailing but also for the end-users who wait for delivery and choose to do e-shopping instead of in-store shopping. Delivery service can be used as a differentiated factor by e-retailers and win customers through customized delivery services.

In Greece electronic commerce has exhibited considerable growth during the last two years, and this upward trend is expected to continue in the forthcoming years. Three million Greek consumers perform online shopping spending an average amount of 1,600 euro whereas the Greek e-commerce sales reached 4,5 euro billion. One of the main reasons of the increasing trend of e-shopping is due to income reduction and the imposition of capital controls which made Greeks more price sensitive. The five top categories for online purchases are travel services reaching at 84%, followed by hotel reservations at 70%, electronic equipment and peripherals at 69%, entertainment tickets at 69%, and apparel and footwear at 62% (ELTRUN, 2018). The average value of an online order costs no more than 25€, it weights no more than 2kg and a great percentage of them can fit into a mailbox (IPC, 2017). Since economic instability is expected to continue and impact on Greek consumers' purchasing patterns and trends, the phenomenon of looking for product offers through e-shopping will continue to be the most important factor driving internet retailing in Greece.

Nonetheless, the organizational structure of last-mile delivery services provided in Greece, is still not so mature as is in other European countries especially like in northern European countries. For example, in the UK, or in Netherlands, alternative delivery methods such as pick-up points (PPs) and automated parcel stations (APS) equipped with lockers (Morganti, et al., 2014), have developed and provide more flexibility for consumers to collect their online orders. Having processed a field review about alternative options to home deliveries in Athens, there are the following three main alternatives:

- Delivery to physical stores: A smart business model was developed by 'Clever Point' which has organized delivery and return services of online orders through selected physical stores, like mini-markets, petrol stations or other convenience shops. On the one hand physical stores gain potential customers and on the other e-shoppers can choose the store that is more accessible to them. This solution can be developed further to other cities in Greece, depending on the success of the cooperation between e-retailers and physical stores.

[1] Corresponding author: alexia_iracleous@yahoo.gr

- Delivery to Parcel Stations at petrol stations: 'ACS' is a Greek courier company, which besides its own physical store network, has developed a parcel network with the cooperation of Shell Petrol Company throughout Greece. This network which is named 'ACS Smart points' consists of Automated Parcel stations which are installed in Shell's petrol stations. Consumers can receive and send their online order using these points, which are a safe place, operating 24 hours and 7 days per week throughout the whole year. In addition, consumers are informed through SMS and e-mail about the status of their online order.
- Postal offices: 'Hellenic Post' S.A. is the national provider of postal services in Greece, which has the most extended network throughout the country and is used by many national and international e-retailers to deliver online orders to end-users. Postal offices are a secure method that is used also for parcel returns, by many European e-retailers as they have proceeded with contract agreement with Postal Operators to offer this service for free to consumers.

The aforementioned delivery service methods to distribute online orders, depicts that in Greece the organization of last-mile deliveries is still under development and presents a great measurement challenge to investigate deeper and understand the demand side of this sector, that is the aim of this research to consider consumers' point of view.

The theme of last-mile deliveries and e-shopping has drawn a significant scholars' and practitioners' attention. There has been an extensive research about the issue of alternative delivery locations, like pick-up points, a very popular solution for parcel service providers as they can achieve very high first-time delivery rates (McKinnon, 2003; Xu et al., 2014; Morganti et al., 2014; Andriankaja, 2012; Stanislaw et al., 2015). Further to this, the issue of change in time of delivery was investigated as far as in what extent consumers have the option to choose a certain time-window to receive their online order (Campbell and Savelsbergh, 2006; Deketele et al., 2011; Agatz et al., 2011). To this end, there are many studies about influencing the consumer behavior to choose home delivery or pick-up point, based on the idea of changing delivery pricing, Agatz, et al. (2008). Other studies describe models about shopping trips within the context of comparing the benefits between e-shopping and in-store shopping (Mindali and Weltevreden, 2013). A significant number of studies in the fields of psychology, marketing, information systems and operations management have identified various factors that encourage consumers to shop online (Cheung et al. 2005; Darley et al. 2010; Monsuwe et al., 2004). Although, there has been an extensive research, less is known about consumer behavior and the impact on the concept of delivery service attributes for e-shopping. This paper aims to contribute to the fields of marketing and operations by identifying and describing this research gap and pointing out the need for future research. In consequence the research question that this paper is examining is the following.

What are the structures of e-shopping characteristics that lead consumers to increased preference to choose specific delivery service attributes?

Through these structures operational logistics managers and delivery operators (the supply side) will be able to gain a better understanding on customers' behavior how they are motivated to proceed with e-shopping and select specific delivery service attributes. More specifically the results of this research will be used to measure the significance of delivery service attributes with the scope to rationalize last-mile logistics services. However, there is another goal of this research, and this is to include practical experience to academic research and show that academic research can coincide with the interests of managerial practice. The survey conducted for this research took place in the city of Athens (Greece), where the greatest volumes of parcels are moving. The rest of the paper is organized as follows: section 2 reviews literature, section 3 explains the data collection and estimation, proposes the model framework and formulates hypotheses, and discuss research's results and section 4 concludes the paper.

2. Literature Review

The consumer delivery service system can be seen as a series of markets in which the desires of households and individuals (i.e. the demand side) are constrained by the opportunities offered to them (i.e. the supply side). More precisely, parcel delivery services for e-shopping is a kind of 'derived demand' originating from the direct demand for e-shopping. Consumers demand for a parcel delivery service, mostly not because they really need it but because they want to conduct e-shopping activity (Hsiao, 2009). Although the provision of delivery service for e-shopping is an issue between e-retailer and transport service provider, the services to be developed need to identify consumers' demand and especially under what conditions a customer is willing to pay for these services.

Consumers prefer e-shopping towards in-store shopping due to the higher convenience that it offers them, such as more product information and choices, the ability to compare products and prices and the potential to shop from any place at any time avoiding shopping trips. An important factor that determines the choice of e-shopping towards in-store shopping is the product type and value. Belonging to a particular product class has implications for the manner in which individuals gather information (Mindali and Salomon, 2007), purchase and choose delivery service type (Zhai, et al., 2016). Consumer products can be loosely categorized into three groups although a given product may have some qualities of two or all three of the groups (Chiang and Dholakia, 2003; Klein, 1998; Peterson et al., 1997). The first product type includes search products, which are those whose qualities a consumer can determine without any inspection prior to purchase, like books and CDs. The second category involves experience goods/ services, such as vacations and restaurants, as well as apparel and shoes which require actual experience prior to purchase in order to ascertain their quality. Last is the category of credence goods/services (e.g., legal and financial services) which require specialized knowledge, such that a consumer may have difficulties evaluating the quality even after consumption (Hsieh et al. 2005). The value and type of product, within the B2C market may be regarded as an explanatory variable that can determine the delivery service attributes chosen, like the speed (e.g. groceries), or request for value-added services (e.g. signature, cash on delivery, extra insurance, etc.).

Having chosen to proceed with online shopping and which product type to purchase, this decision relates with consumers' e-shopping motive, either to fulfill a utilitarian intention (functional or tangible) or hedonic (pleasurable or intangible) (Salomon, et. al., 2010). Depending on which motive consumers choose to shop online, they express different behaviors (Lim and Cham, 2015; Rohm and Swaminathan, 2004). Utilitarian motive refers to the desire to achieve some functional or practical benefit, whereas hedonic motive concerns an experiential need, involving emotional responses or fantasies. Sane and Chopra (2014), as utilitarian motives proposed, discounts, personal attention, membership, product quality, reasonable price, brands availability and product variety. These consumers who manage to purchase the product of their interest at a good offer, their utilitarian motive is realized and increased.

E-shopping incorporates, also hedonic elements, which have to do with emotional or experiential aspects of e-shoppers. Consumers aim to obtain hedonic value through arousal, playfulness, and positive affect from interacting with an online store (Bridges and Florsheim, 2008). Sane and Chopra (2014), proposed as hedonic motives status, branded products, ambience, relieve stress, enjoyment, mood improvement, hobby, exercising, store reputation, new trends. Consumers who are driven by their hedonic motives to shop online, they may select products which provide pleasure and influences positively their attitude, which in turn may positively affect the propensity of online purchases (Kim and Eastin, 2011).

In terms of delivery services, hedonic motives may lead consumers to choose a faster delivery service comparing with utilitarian motives which may concern to save travelling expenses to physical stores, thus, prefer a slower delivery service. However, previous researches have documented that online shoppers are driven by both utilitarian and hedonic dimensions, which together formulate the online shopping experience (Solomon, 1999; Childers et al., 2001; O'Brien, 2010; Overby and Lee, 2006) and influence online shopping decisions (Bosnjak et al., 2007). Both motives can be complementary and satisfy both needs (Holbrook and Hirschman, 1982; Ozturk et al., 2016), thus to influence consumers' decision-making regarding e-shopping which is directly connected with delivery services.

Apparently, e-shopping can be fulfilled by a delivery system that can satisfy both consumers' and retailers' needs. Having studied the academic literature and advised the delivery service provider's price catalogue, as well as e-shop's offered services, the below attributes synthesize the delivery service provided, and these are the following:

- Delivery point;
- Delivery time and speed;
- Track and trace;
- Value added services;
- Delivery price.

Delivery point is the first thing that consumers need to determine after completing e-shopping. They are two main options, either to provide an address that can be at home or at workplace or to choose to collect online order from a pick-up point if this option is provided by e-retailer. Pick-up points is an alternative solution to home delivery, like automated parcel stations, which can increase the consumer's willingness to pick up the goods instead of using home delivery. This type of service is widely offered to consumers in northern European cities, and is mostly provided by postal and logistics operators (Morganti et al., 2014). The critical issue that needs to be considered here, is that these points need to be close to living areas, such as close to consumers' residences, on the way to work, close to shopping centers, to public transport stations, close to parking and in secure locations. Iwan et al., (2016) analyzed the usability and efficiency of automatic collection points based on the postal company's experience in Poland and concludes that it seems to be the major direction in the near future, to evolve into more structured distribution channels to serve e-shoppers and aim for more consolidated shipments that is a sustainable solution for the environment.

The concept of time and speed of deliveries, that is the total time between order placement and delivery to consumer, is one of the main factors that impact on the choice of delivery service attributes. Parcel service providers, segment their price catalogue on delivery time into same day, next day, or two and more days, as well as delivery to specific time-slots and develop different logistical approaches (Huebner and Kuhn, 2016). Time of delivery is a determinant factor for delivery service, but also for online shopping. Consumer wish to deliver his/her online order immediately after completing e-shopping, thus the aim is to minimize the time that customers can wait to receive their online order. They may require time-based delivery service in order to control the trade-off between home delivery and pick-up point by being able to select a pre-defined delivery time slot in advance (Agatz et al., 2011). The issue of providing a specific delivery window implies that small delivery windows will produce the highest customer satisfaction. Agatz et al. (2008), proposed time alternative, like morning or afternoon timeframe, potential of deliveries on Saturday, to deliver to neighbor or to service points. Goebel et al. (2012) researched a service offered to consumer that is the choice of a pre-defined time slot and found that consumers who perceive a delivery service as more valuable are willing to pay more for that service. The more precisely the customer can control or select the desired time slot, the higher the cost for retailers. All in all consumers are willing to pay up to a certain amount of delivery fee and receive their order the same day, if it is a local e-shop, instead of waiting some days. Furthermore, consumers who perceive this convenience enhancing service as attractive, represent a market segment that has significant revenue potential. Miyatake, et al. (2016), studied, time windows delivery service and is suggested that in case of a second pre-arranged delivery service in which consumer will be absent, then he/she should pay an extra delivery charge as a penalty. This service can be applied successfully as long as there is a pre-arrangement between the service provider and the consumer, so as to

arrange home availability depending on working hours per week. By offering time-based delivery services may allow logistics service providers to invest in more convenient technological interfaces such as more frequent communication through sms or email.
Consumers get information regarding the order status of their electronic purchase, right after having completed their online order which informs them about the date and tracking number of order dispatch. Then consumers are directed to parcel providers' web site to continue with tracking. Track and trace are services based on automatic identification of the parcels' location and status by use of technologies such as RFID, barcodes, and are the most important services for e-shoppers. Electronic data for order status allow the customer to have the feeling of shipment control and arrange his/her presence at home at the time of parcel delivery. This feature has a significant impact on repurchase intentions (Cho 2015; Liao et al., 2010, Rao et al., 2011). However, in case of cross-border e-shopping, due to lack of information systems' interoperability between delivery operators, end-to-end track and trace is not guaranteed.
The price of delivery service, is another important factor in consumer's decision-making. Service delivery pricing, is known as the shipping fee, and reflects the costs of physically moving the product from one place to another as well as it reflects the value-added services that a consumer may have selected to receive his/her online order and these may involve delivery within a certain time, cash on delivery, extra insurance or any other personalized service. Although, delivery service is provided for free to consumers, when the online order is above a certain amount, this doesn't mean that shipping cost is for free, rather than the price of delivery service is included in the product. In consequence, the delivery price paid by the e-shopper to the e-retailer does not necessarily reflect the delivery price paid by the e-retailer to the delivery operator. As delivery service has a critical role to e-shopping, and affect retailer's and consumer's cost, it is better for e-retailers to clearly introduce the delivery price independent from the price of the items, (Miyatake et al., 2016). A significant factor to delivery price plays the geographical area, in terms of residence disparity as window deliveries in urban areas can be lower than standard deliveries within rural areas (Gevaers et al., 2014). Whereas some e-shoppers only care about paying a low delivery price, others are prepared to pay more for delivery in exchange for extra services, faster or more convenient delivery. Speed and cost are the two factors that are crucial to the success of last mile delivery (Chen and Pan, 2015).
Consumer behavior is influenced by all the above described factors throughout the decision process of e-shopping and delivery service. In addition, it counts the experience of the previous e-shopping activity, whether consumer was satisfied from the whole service provided (Chang, Wu, and Lai, 2010; Monsuwé et al., 2004), which if it was positive then will lead to repeat purchasing in the future (Monsuwé et al., 2004; Zhou et al., 2007). It should be mentioned, though that the majority of e-shoppers' purchasing experience is directly linked to the quality of the delivery service that the seller provides them. In consequence, delivery service can provide value to the total e-shopping process.

3. Methodology

3.1. The Proposed Model and Hypotheses

Based on the literature review, it is proposed an integrative model framework to understand what factors impact consumers to choose delivery service attributes to receive their online order (Figure 1). This framework provides the attributes of delivery service, as well as the links with consumer's characteristics, household characteristics, e-shopping characteristics and e-shopping motives.

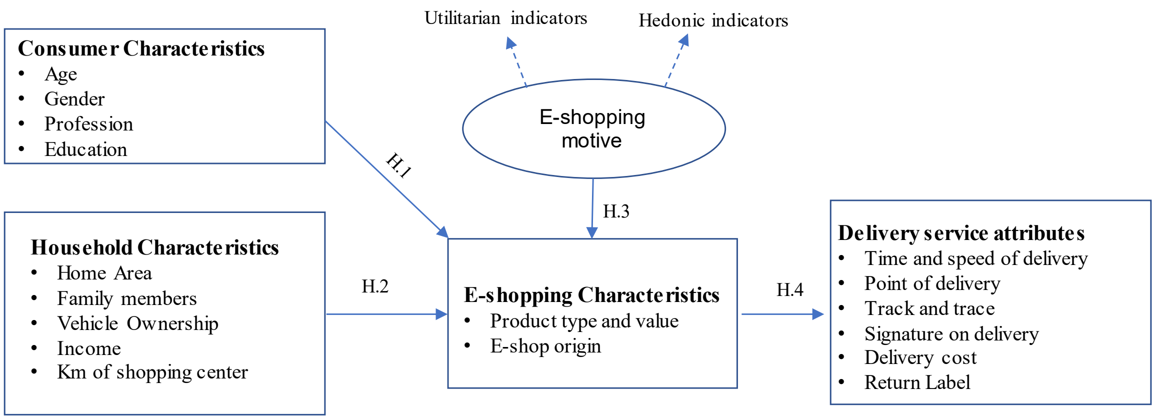

Fig.1.
Modeling Framework for last-mile delivery services

In this model, the effect of each of the variables was examined and four hypotheses for testing the relationships between the variables of the framework were formulated and produced. These are the followings:

- H1. E-shopping characteristics (product type and value, e-shop origin) are dependent to consumer characteristics (age, gender, profession, education)

- H2. E-shopping characteristics (product type and value, e-shop origin) are dependent to household characteristics (Home Area, Family members, Vehicle Ownership, Family income, Km of shopping center)
- H3. E-shopping characteristics (product type and value, e-shop origin) are dependent to e-shopping motive (utilitarian, hedonic)
- H4. Delivery service attributes (Time and speed of delivery, Point of delivery, Track and trace, Signature on delivery, Delivery cost, Return Label) are dependent on e-shopping characteristics (product type and value, e-shop origin).

An online survey was conducted to collect data on consumers' most recent e-shopping experience. Questionnaire was developed using Sawtooth Software, and disseminated through internet social networks. The survey took place in the period of March to May 2018 and data were then analyzed using SPSS statistical software package. The total number of valid questionnaires that were collected was from 140 respondents.
The table below presents the delivery service attributes and attributes' levels that were measured for this research.

Table 1
Delivery service attributes and levels included in the questionnaire

Index	Delivery service attributes	Attributes' levels
1	Delivery point	• at home • pick-up point
2	Time and speed of delivery	• Standard delivery (3-7 days) • Express delivery (1-2 days) • Next day delivery
3	Electronic notifications for status delivery	• Order status notifications (email/sms) from the transport company • Order status notifications (email/sms) from the e-retailer • Through special mobile application of the transport/courier company • Through the transporter's/ courier website
4	Value-added services	• Signature • Return label
5	Delivery cost	• Free delivery (e-shop offers it as a standard service) • Free delivery (the order value was above the limit to cover free delivery cost) • 1-3€ • 3-6€ • >6€

The results of the questionnaire showed that the gender distribution was 51% percent of male and 49% was female. The greatest age category, 42% falls in between 37-45 years old, whereas 27% who replied were in the age category between 27-36 years old. The majority of the respondents 70% were well educated as they hold an Msc or Phd degree while 74% have a full- time job. The top three categories of products purchased were apparel and shoes at 34%, then were pharmaceutical and cosmetics at 31%, electronic devices at 19% and pc equipment at 16%, whereas 54% of the online orders had a value between 31-80 euros. The greatest majority of e-shoppers 64%, shop from Greek e-shops.
The monthly household income was evenly distributed close to 20% for each of the four income categories, of 500-1,000€, 1,001-1,500€, 1,501-2,000€ and 2,001 -2,500€ whereas a slight increase 24% lies in the fifth income category of >2,500 €. In terms of geographical location, the greatest majority of consumers 86% live in the urban area of Athens, that is close to the city center, thus the distance to the closest shopping area is no more than 5km. Regarding vehicle ownership, almost everyone, 94% owns a car, while approximately 41% own a bicycle, too. Most of the respondents 28% live in a house with 3 members, whereas households with 2 or 4 members have the same percentage that was 24%.
Figure 2 below presents the delivery service characteristics that were selected by respondents, to receive their online order. Standard delivery method was chosen with great difference at 80% compared with the other two methods in terms of time velocity. The preferred point of delivery was at their home address at 63% and then at their office address at 29%. However, 53% of respondents reported that they received track and trace information from the e-shop and 33% from transport company. Half of the consumers 51%, didn't sign to receive their parcel. The greatest percentage of e-shoppers received their order with free delivery either as an option offered by the e-shop at 27% or due to the amount of order that was over the limit which provides free shipping at 33%. However, 17% of respondents paid less than 3 euros to receive their online order. Finally, a return label wasn't found by 44% of the consumers.

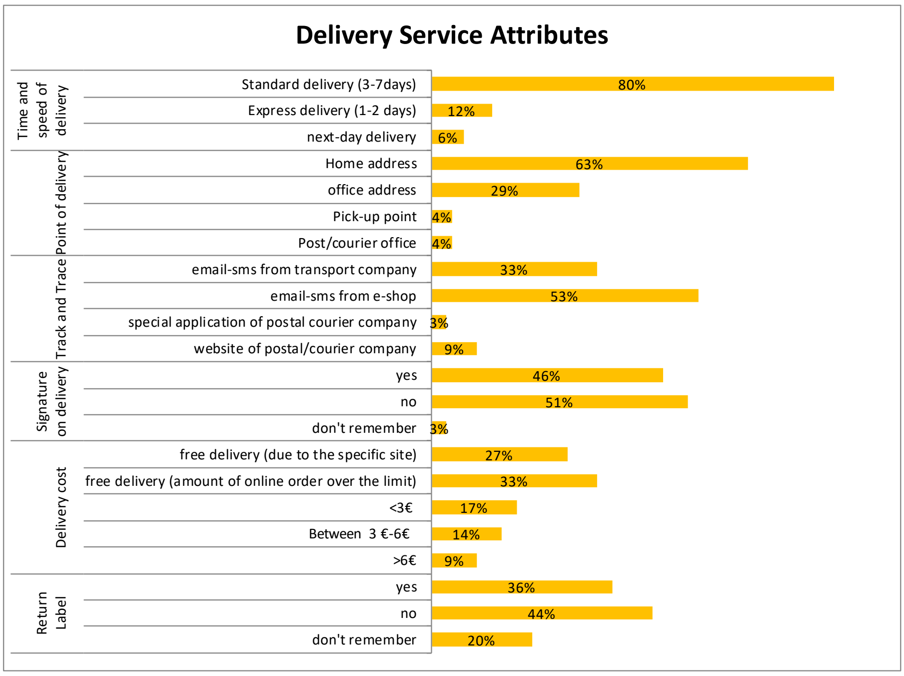

Fig. 2.
Delivery Service Attributes chosen to receive online order

As far as e-shopping motive is concerned e-shoppers have rated high at 53% 'the convenience that an e-shop offers them to shop any time from any place', as well as 'the detailed product information that they can find' at 24%. Further to the utilitarian motives, 39% of consumers replied that they 'feel great satisfaction when they find to shop products of the last trend' and 25% when 'they find offers and sales'.
Applying chi-square test it was tested H1. and it was found that, only three types of products were statistically significant with consumers' characteristics. These were pharmaceuticals and cosmetics (χ^2=6.801 and p=0.009), and apparel and shoes (χ^2=9.575 and p=0.002) which were statistically significant with gender, and more precisely with female as is the majority who shop these two types of products. The third type of product, is PC equipment (χ^2=4.859 and p=0.027) which was statistically significant with profession as well as e-shop origin (χ^2=13.327 and p=0.001). All other types of products and their value had no statistical significance with the consumers' characteristics.

Table 2
E-shopping characteristics vs. consumers' characteristics

e-shopping characteristics	**Age**	**Gender**	**Profession**	**Education**
Groceries	1.558 (0.459)	0.203 (0.652)	0.037 (0.848)	0.630 (0.427)
Pharmaceutical	2.199 (0.333)	6.801** (0.009)	0.321 (0.571)	0.007 (0.934)
Apparel and shoes	0.814 (0.666)	9.575** (0.002)	0.282 (0.596)	1.580 (0.209)
Office consumables	2.840 (0.242)	1.029 (0.310)	2.159 (0.596)	0.183 (0.669)
Kids products	5.448 (0.066)	0.501 (0.479)	0.643 (0.423)	2.294 (0.130)
Household product	5.205 (0.074)	0.686 (0.407)	2.210 (0.137)	0.358 (0.550)
PC equipment	1.880 (0.391)	2.933 (0.087)	4.859* (0.027)	0.145 (0.703)
Electronic devices	2.859 (0.239)	0.502 (0.479)	1.101 (0.294)	0.901 (0.343)
value (1-30 euro)	0.281 (0.869)	0.026 (0.873)	1.602 (0.303)	0.084 (0.772)
value (31-80 euro)	3.667 (0.160)	2.403 (0.121)	0.100 (0.752)	0.521 (0.471)
value (81-150 euro)	1.792 (0.408)	0.147 (0.701)	1.679 (0.195)	0.045 (0.833)

e-shopping characteristics	Age	Gender	Profession	Education
value (251-350 euro)	0.372 (0.830)	1.029 (0.310)	0.690 (0.406)	0.630 (0.427)
e-shop origin	6.382 (0.172)	2.873 (0.238)	13.327** (0.001)	0.017 (0.992)

*p<0.05, **p<0.01

As far as household characteristics' variables are concerned, none of them which have tested have shown statistical significance with any of the e-shopping characteristics, thus this model component is rejected and its variables can be measured again under a different category.

In order to test e-shopping motivation, with the products that were found to be statistically significant with consumers' characteristics, Mann Whitney test was applied, and the results are presented in the table below.

Table 3

E-shopping motivation in relation with e-shopping characteristics

E-shopping motivation	Mann-Whitney U	Wilcoxon W	Z	Asymp. Sig. (2-tailed)
Pharmaceuticals and Cosmetics				
Better control to my consumption habits	1518,000	6271,000	-2,614	0.009
The feeling of satisfaction finding products of last trend	1619,000	6372,000	-2.186	0.029
Apparel and shoes				
The feeling of satisfaction when I found offers and sales	1752,000	6030,000	-2.040	0.041
PC equipment				
The convenience to shop whenever I want from any place	956,500	7977,500	-2.139	0.032
The detailed product information that I can get	963,000	7984,000	-2.024	0.43

Reporting Mann Whitney test showed that there was a statistical significance (U= 1518,000, p = 0.009) between the utilitarian indicator 'Better control to my consumption habits' in relation with pharmaceutical and cosmetics product category as well as with the hedonic indicator 'The feeling of satisfaction finding products of last trend' (U=1619, 000, p=0.029). Following this, the hedonic indicator 'The feeling of satisfaction when I found offers and sales' with apparel and shoes product category was found to be statistically significant (U = 1752,000, p = 0.041). Regarding the Utilitarian indicator 'The convenience to shop whenever I want from any place' shows statistically significance (U = 956,500, p = 0.032) with PC equipment as well as with the 'The detailed product information that I can get' (U=963,000, p=0.043).

Concerning delivery service attributes relating with e-shopping characteristics applying chi-squared tests, the results are summarized in the table below.

Table 2

Results of Delivery service attributes towards e-shopping characteristics

Delivery service attributes	χ^2	*p*	E-shopping characteristics
Standard delivery (3-7 days)	6.117 4.193 7.546	0.013 0.041 0.023	Pharmaceuticals and cosmetics Apparel and shoes Country of e-shop
Next day delivery	5.818	0.016	Groceries

Delivery service attributes	χ^2	p	E-shopping characteristics
Electronic notifications for order status	10.233 9.153 25.803	0.037 0.027 0.001	PC equipment Product value (31-80 euro) Country of e-shop
Return label	10.933	0.027	Country of e-shop
Delivery cost	21.002 28.765	0.000 0.000	Product value (1-30) Country of e-shop

The above results show that next day delivery was applied only for groceries products, while products that were mostly preferred to be purchased by our respondents like pharmaceuticals and cosmetics and apparel and shoes, the issue of time delivery was not so significant as they have chosen the slowest method. The provision for electronic notifications was requested for PC equipment, a product type that was preferred mostly by men rather than by women. Goods that their value was in the value category of 1-30 euros, the issue of delivery cost was important, while for products' value that is 31-80 euros electronic notifications were important. What is interesting to notice is that delivery services, such as standard delivery method, electronic notifications, delivery cost and return label are all significant with the e-shop origin. Whereas point of delivery was not a significant factor with any of the e-shopping characteristics.

3.2. Discussion of Descriptive Statistics

The great difference between standard delivery method and express delivery shows that respondents are interested more in saving cost rather than time of delivery. Only for groceries next day delivery was an important issue and this can be explained as is a type of product that need frequent replenishment for a household and is a necessity.

Regarding point of delivery, online orders are delivered at consumers' place either at home address or at the workplace. There were very few choices for pick-up points, which shows that either this method is not provided by e-retailers at their e-shops or even if it is provided consumers can arrange successful home delivery. When consumers complete their online order, receive an order notification message and then it follows a message for the day of order dispatch which refers to the tracking number. Having received this tracking number, consumer usually diverts to transport provider's web page to track for order status. In this survey results have shown that respondents were receiving order status notifications from the e-shop rather than the parcel provider company. This can be explained that since the majority of e-purchases were performed in Greek e-shops, the delivery time was short, so since consumers were receiving a message notification about order dispatch, then they may not have continued tracking their items to parcels providers' web site, where shipping status is displayed. In case of an e-purchase from a foreign e-shop then order status notifications could be checked more frequently by consumers. A substantial last-mile issue in home deliveries occurs if a signature by the person stated on the parcel's address is required, as this element reassures delivery by a specific person. But, in this survey this characteristic doesn't seem to have a significant meaning, whereas it could be of high importance in case that the order is exclusively for personal use or the receiver doesn't want to know other family members about his/her online order. In case that signature is not of high significance, then order can be received by any other person who is at home, and avoid delivery failure. The top three product categories chosen were apparel and shoes and pharmaceuticals and cosmetics mostly by women, while PC equipment was most frequently purchased by men. This shows that gender plays an important role to product type as well as the profession. This finding comes to an agreement with Clemes et al., (2014) who states that gender has an influence on e-shopping behavior. The product value category of 1-30 euros was a preferred category by consumers, but it was found that delivery cost has a significant role. The option of free delivery can be offered to this type of value of products, in consequence this may be an issue for e-retailers to think and find a method to provide free delivery. Although household size impact on e-shopping activity and more precisely on the frequency (Zhou and Wang, 2014), comparing with singles who tend to do less online shopping (Farag et al., 2007), in this survey this model category didn't impact on e-shopping characteristics. The variables that constitute household characteristics will be measured under different category.

Consumers are more sensitive to receive electronic notifications as the value of product is rising. Consumers' motivation is an important element to consider and together with e-shopping characteristics and individual characteristics to develop customized delivery services. Most researchers focus on motives relative with product, in consequence there is an opportunity to examine deeper in terms of delivery services. Apparently, consumers from Athens, are motivated to shop online because of the convenience that e-shopping offers in terms of time, place and product information towards physical stores, and for finding sales and good offers as well as purchasing goods of last trend that these can not be found to physical stores. However, they are also induced to shop by hedonic motives, such as the desire to find the last trend in the desired products, so both motivations influence consumer behavior. These findings

concur with other researchers' that e-shopping motivation, can be driven either to maximize utility for practical reasons or to gain as much pleasure, (Kourouthanassis et al., 2008).
Country of e-shop is a determinant factor for electronic notifications, time of delivery, return service and delivery cost. Although the respondents in this survey have mostly purchased from a Greek e-shop (64%), the origin of e-shop whether concerns domestic e-commerce or cross-border, seems to generate different behavior for delivery service. This can be explained by the fact that local markets apply different marketing strategies for customer service. In addition consumers who shop from a local e-shop can access easier the e-retailer in case they meet any problems with their online order. Apparently, e-shoppers' attitudes and preferences should be the object of additional investigation to integrate their impact on shaping last mile operations. Knowing consumers' preferences will provide feedback to develop consumers' segments depending on their specific individual characteristics, motivations and e-shopping characteristics and provide a competitive advantage firstly to e-retailers and then to parcel providers.

4. Summary and Conclusion

In this article, it was attempted to examine e-shoppers' most recent e-purchase experience and define these components of e-shopping and motivation characteristics that lead consumers to choose specific delivery service attributes. The developed model framework provides an insight into the potential interactions between consumer behavior and logistics operational procedures of e-shopping so as to develop marketing strategies for different delivery service types provided to e-shoppers.
Based on these preliminary results, it can be assumed that e-shoppers choose to shop online mostly driven by their utilitarian motives, chasing for offers and discounts, and then from hedonic motives, gaining satisfaction of acquiring a product of the last trend. However, there is a place for further investigation, as the sample of this survey was taken from the city center of Athens, where shopping opportunities are to a very close proximity, whereas results can be different if consumers where living in rural areas.
These approaches are consistent with the aims of this paper in order to understand consumer behavior and how they react to delivery service attributes. These findings provide feedback to the supply side of e-commerce market, in order to develop specialized retail chains based on product type and value, develop their information systems concerning tracking and tracing, and the options of delivery service that the e-shop can offer to consumers. Last-mile networks need to be very agile, and provide an efficient delivery service system, that can offer various services and predict consumers' behavior. Future logistics models should focus on controlling the last mile distribution service quality rates of customer satisfaction.

THE NEW APPROACH FOR THE POSTAL SERVICES USING CITY LOGISTICS METHODS

Inna Zelenska[1]**, Libor Švadlenka**[2]

[1,2] University of Pardubice, Faculty of Transport Engineering, Czech Republic

Abstract: This paper focuses on the vehicle routing problems found in cities for goods distribution generally called as City Logistics which is a very discussed topic in recent years. Appropriate selection of the city logistics methods can help to remove the urban transport problems from the city with the constraints of space and with the need to clean the already damaged environment. That is currently, according to the research, one of the biggest problems for the big as well as for the small cities. The main aim for the area of City Logistics is to minimize the frequency of journeys of the supply vehicles in the cities, especially in the cities centers and by this minimization bring the environmental impact due to the added value of the service itself. Purpose of this paper is to explore the new city logistics problems and solutions and present some selected possibilities where the City Logistics services can be transferred to the postal services in the Czech Republic. One of the selected solutions is a consolidation of consignments at the spot of transshipment and then subsequently delivery of that consignment using a new approach. The paper itself can be divided into the three main parts. The first part focuses on the domestic as well as international research with an aim to bring a comprehensive overview of the City Logistics services. In the second part of this paper is an analysis of the current state of the City Logistics in the connection with the postal services. The new approach designed by the authors of this paper is in the third part.

Keywords: city logistics; postal services; consolidation of consignments.

1. Introduction

Currently, the ever-growing urbanization trend of large, medium and small sized towns is the object of interest not only for city logistics experts, but also for politicians and the public. The main reason for such attention is the negative economic, environmental and social impact of urbanization. Negative impacts include high congestion, noise, polluted air, vibrations and higher logistics costs in the city. While higher logistics costs are reflected in higher product prices, external effects in the form of polluted air and noise can cause various civilization diseases and generally a lower quality of life in the city. Tadić et. al. (2015) underlines that local authorities are aware of the importance of organization and control the current logistics chain situation in the cities, but most of the local authorities do not know how to minimize the negative impact of logistics activities on the economy, environment and quality of life in the city. According to the United Nations research, more than 54 percent of the population currently live in urban agglomerations. The prediction of the United Nations, according to which 66 percent of the population will live in cities by 2050, is alarming and there is a need to look for ways to ensure sustainable urban development. Tadić et. al. (2015) pointed out that besides the growth of the urban population, the trend of growing goods flows is continuing, which leads to increased activities of road freight and light commercial vehicles. Quak (2008) detailly described the negative impacts of growing trend of road transport, which are related to the economy (increases prices), society (damages to human health, accidents, noise and lower quality of life in the city) and environment (emissions and consumption of non-renewable energy). Witkowski (2014) characterized city logistics as a process of planning, implementation and monitoring effectiveness of people, freight transport and information flows in urban areas in order to improve the quality of life in the city. Tadić et. al. (2015) pointed out the role of transportation in city logistics, which consist in a reduction of the number of empty vehicle-kilometers and control the number, size and characteristics of the freight vehicles. All of it is to achieve a city logistics goal, which is to increase efficiency and minimalize the negative impacts of the logistics process and support the sustainable development of urban areas. All the authors outlined sustainability as a way to ensure economic, ecologic and social prosperity. Taniguchi et. al. (2013) outlined a need to create a balance between smart economic growth, transportation and cleaner, safer, quieter agglomerations and a risk of disaster due to global climate change. According to Brundtland (1987) sustainability can be characterized as a development that provides the needs of presents and do not compromise the ability of future generations to ensure their own needs. Russo (2010) described a worldwide Sustainable Development Strategy which aims to create a continuous long-term improvement in the quality of life by managing and using resources efficiently, developing economic and social sustainability in terms of efficiency and safety and environmental sustainability in terms of air pollution.

2. What Have We Learn About City Logistic so Far?

Nowadays attention is being paid to issues of sustainability all over the word, in some cities they have begun developing smart cities projects or at least their concepts for future realization. An inseparable part of the smart cities projects is city logistics, which is responsible for the logistics processes and the sustainable transport in the city. According to Taniguchi et.al. (2001) city logistics is "*the process for totally optimizing the logistics and transport activities by private companies with support of advanced information systems in urban areas considering the traffic environment, the traffic congestion, the traffic safety and the energy savings within the framework of market economy*". Kauf (2016) defined that a main city logistics task is to improve the quality of life in cities for their residents and ensure

[1] Corresponding author: st38775@student.upce.cz

competitiveness of businesses located in the city. Russo (2010) outlined the importance of consideration of different interests before implementing city logistics measures, means an investigation of the relations and the interests of urban transport stakeholders. It follows from the above that it is necessary to perceive the concept of city logistics comprehensively and take into consideration the needs and objectives of all stakeholders. Pursuant to Taniguchi and Thompson (2014) the four main stakeholders are: shippers, freight carriers, administrators and residents.

Residents are the most numerous group of stakeholders, they are the one who create the commodity and the transportation flows in the first place. The more residents that live in the city, the bigger the demand in restaurants and the shops, which lead to increased transport flows. Another reason of increased transportation in the city is growing e-commerce, due to the fact that residents more often buy things on the Internet and require delivery as soon as possible. That' leads to an increasing number of freight vehicles in the city and lower loading factor. According to Demkes et. al. (1999) logistics providers trying to satisfy customer needs are more often focused on the effective time management instead of focusing on effective transport methods, which implies an increase of running vehicles and thus the vehicles-kilometers.

Logistics providers or freight carries represent another major stakeholder, which can influence the logistics situation in a city. Freight carriers are the ones who decide which type of freight vehicle is used for transportation, the one who arranges the routing for vehicles and the one who is responsible for the loading factor. The main problem is the different goals of city logistics and freight carriers. While city logistics is focusing on sustainability in terms of ecology and society, the freight carriers focus on their incomings. According to Tadić et.al. (2015) as a result of such discrepancy, freight carriers provide their services without needed coordination, in most cities urban freight transport is very inefficient, which means that the same amount of goods can be delivered with a smaller number of vehicles-kilometers, but with the same or even better quality of service. The studies show that logistics services providers are mostly small companies, which have a lower utilization factor of the vehicles cargo space.

Another group of stakeholders, which is according to Witkowski (2014) plays the most important role in the city logistics system is the administration or government. The main goal for the administration should be a sustainable development in the city and ensuring high living standards in social, economic and environmental issues. Autor Witkowski (2014) outlined the most important tasks for administration related to each issue. In social areas it is ensuring the safety of residents and education of residents about the protection of the environment. In the case of economics, the main goal is to reduce the costs associated with the movement of people and cargo and in case of the environment the main aim is to reduce emissions of CO_2 and NOx and noise reduction in the city. Tadić (2015) pointed out that the local authorities or administrations in European cities provide a lot of regulations and measures in order to increase consolidation, cooperation and coordination and thus raise the efficiency of the city's logistics. On the other hand, author outlined often inadequate decisions of authorities, which are made without the analysis of the existing situation, its surroundings and the impacts on the overall city's logistics system. Several authors (Allen et.al, 2000; Quak, 2008) agreed that often prohibitive and restrictive measures like restrictive measures concerning the load capacities of vehicles or time for accessing the selected zone in the city, has a negative impact on logistics activities, instead of making them more effective. Tadić (2015) underlined that restrictions and prohibitions in a city's logistics cannot be the solution itself, this requires a certain level of understanding of all stakeholders' activities and decision-making processes while considering the consequences for the entire system of city logistics.

The last group of stakeholders in a city's logistics system is the shippers, which represents different shops and restaurants as well as e-commerce retail. Shippers, in order to ensure high quality service for their customer and incomes for themselves, require the goods to be delivered on time. Often, they force the freight carriers to be punctual and implement a delay penalty, it leads to a non-efficient way of transportation.

Analysis of current city logistics situations and administrator initiatives shows that interaction between the private (freight carries) and public (administrations) sector is deficient, which leads to a lot of misunderstanding and failures of city logistics measures. The main problem is that administrations do not know enough about the problems related to logistic activities in the city and the freight carriers are unable to formulate requirements from the administrations in order to achieve a sustainable city logistics solution (Tadić, 2015). Dablanc (2007) characterized the whole situation as a slowly chancing process, where neither the freight carriers nor administration are willing to make progress, on the one hand the freight carriers are waiting for a right and supportive (financially) initiative from the government and the government, on the other hand, expected freight carriers to set up new logistics solutions, which will satisfy customers and environmental needs, but may not be profitable at all.

The main aim of city logistic is to find a new sustainable solution for transportation and supplying into cities which will be acceptable for all stakeholders. The key to success is based on cooperation and synergy effects generated by participants in the supply chain (Kauf, 2016). During the history of city logistics there has been presented a lot of city logistics methods and assumptions, focused on creating a sustainable city. For example, there are studies about urban logistic terminals, last mile management, different types of consolidation and a reduction in the number of trucks trips in the city. According to Taniguchi (2014) some of the elements are fundamental for creating a sustainable city logistics system. For example, innovative technology for information and communication, Intelligent Transport Systems, cooperation between the public and private sectors and changing the mind-set of logistics managers are some of them. Using information and communication technology (ICT) and intelligent transport systems (ITS) could help the shippers qualify their services by tracking vehicles with GPS, tracking freight containers or palettes, route planning to avoid congested roads based on digital maps and real time traffic information. ITS could also help to reduce operation costs, by reducing the number of trips (Nemoto et. al. 2001).

According to Gonzalez-Feliu et. al. (2013) the most difficult element is cooperation between the public and private sector. The main problem of public-private partnership is the conflict of interests where, on the one hand, is the private sector (shippers, freight carriers, shoppers), who wants to constantly improve the service for their customers, notably by more frequent and smaller supplies of goods. On the other hand, is the side of the administration, who want to coordinate the private sector activities to minimize the environmental and social impact of transport and create sustainable, liveable cities for their residents. The last fundamental element in creating a good city logistic system is, according to Taniguchi (2014), a change in the mind-set of logistic managers, mostly because logistics managers are the main players in urban freight transport systems. They are the one who makes the decisions about whether their company is going to provide a green city solution and educate their employees about sustainable cities and how they can participant or not. The main thought is that we cannot solve 21-century problems with 19^{th}-centure mindsets (Landry, 2012). But are the logistics managers the only ones, whose mind-set needs to be changed in order to create sustainable and livable cities?

2.1. City Logistics Current Situation and the Theoretical Measures

There are different types of city logistics management, which are focused on different management methods and city logistics schemes to arrange environmental, economic and social sustainability in cities all over the world. The key success factor in achieving city logistics goals in every city is a right combination of different city logistics schemes and management methods in order to create a synergy effect.

The first step in applying the best fitting logistics measures in a selected city is finding the current transport situation and the major relating problems in the city. Tadić et. al. (2015) outlined a problem with empty runs of vehicles in the cities due to geographical imbalance, unsuitability of the vehicles and problems with routing and scheduling the vehicles. Geographical imbalance exists due to current logistics organization, when most cities are supplying from logistics centers outside the cities, which increases the transport distance during the supplying and costs reverse empty runs of vehicles. According to Allen et.al. (2012) there are several factors that affect the extent and location of logistics activities for example population density, size and economic structure of the city, operational models and vehicle structures in the realization of flows. Significant impact on urban areas has supply chain organization, means locations of logistics centers, warehouse systems and spatial arrangements within the chain. Dablanc (2007) pointed out the problem with the regulation of city logistics situations, which is the same as 20 years ago, for example identifying the maximum size or weight of trucks authorized to deliver in city centers. Author Dablanc (2007) described a new model of restrictions used in some European cities, which focuses on Euro emission standards of vehicles and the loading factor. According to these restrictions just the latest vehicles and fully loaded trucks can enter the city center. Dablanc (2007) also characterized a problem with the age of vehicles, turns out supplying vehicles trend to be older than the rest of the fleet of the truck industry, which leads to higher environmental pollution in the city.

The second step, after defining the common city logistics problems, which seems to be the same in all cities in Europe and the world, is finding an appropriate city logistics solution. As it was pointed out before, there are a lot of city logistics methods focusing on different types of city logistics problems. Some of the city logistics methods were already applied in the cities and some of them are in the planning phase, it depends on the degree of difficulty and input needed to process the different methods. Less input needed methods like access control to cities are currently more common in cities than for example one of the most expensive measures like an urban consolidation center. On the other hand, the problem with urban consolidation centers (UCC) is very often mentioned in the thematic literature, several publications are focused just on this problem. According to Brawne et.al. (2005) UCCs can be defined as a logistics facility situated in the city center or close to the area, which is supplying from the selected UCC. The key requirements are to avoid the part load deliveries into urban centers and provide facilities like UCC to insure consolidated deliveries by appropriate vehicles (for example smaller vehicles using alternative fuels or bicycles) with a required level of load factor. Due to the requirements below using an urban consolidation center brings a lot of positive effects to the city, for example less pollution, noise and congestion. Moreover, UCC has a positive impact not just on city logistics, but also offering a possibility of value-added services for its users as well, the only question is if they are open for reconfiguring logistics activities or not. According to Gammelgaard et. al. (2016) the benefit for users of UCC has two parts, one is consolidation of different deliveries at the UCC, so the user only receives one delivery per day and the other one is the program of value added services, the range of which can be different due to requirements of users. Gammelgaard et. al. (2016) describes possible additional services as stockholding, pre-tail activities, order process, return logistics, home delivery or last mile solution. Stockholding is a commonly used additional service for UCC costumers, when shipments are not just consolidated and transported to the customer, but also stored for some period. It helps users (for example retails) improve space usage in the store and use of employees. Pre-tail activities often represent control of goods and making goods ready for shelves, for example price tagging. Home deliveries often connected with e-commerce, when UCC can arrange deliveries of goods straight to the final customer. UCC can also provide added service at the delivering place as unloading at the right place, unpacking or even putting goods on shelves in the store, so store personal can take care of the customer at the same time (BESTUFS, 2007). All these value-added services aim–to persuade stores or restaurants in the city to use UCC for their deliveries in order to achieve sustainable transportation in the city. Another value-added service which UCC can provide is reverse logistics. Efficient reverse logistics is very important in the aim to achieve city logistics goals. Nowadays reverse flows of packaged material or returned goods is a noticeable problem for efficient city logistics in cities. According to the Reverse Logistics Executive Council reverse logistics is a specialized segment of moving goods, which starts after the sale and after delivery to the customer. Anthony (2005) characterized reverse logistics as the process of returning finished products for replacement, repair, or credit. Reverse logistic according to the author is often very costly for retail or logistics providers, but at the same time represents a necessary part of maintaining an efficient supply chain. Efficient reverse logistics plays an important role not just in the cost structure of it provider, but also in efficiency of whole city logistics organization. Reverse flows of returned goods from customer are difficult to organize and often causes additional runs of vehicles with very low load factor. That leads to additional environmental pollution, noise and congestion in the city. As it was pointed out before, there are a lot of city logistics methods focusing on different types of city logistics problems, Taniguchi et. al. (2014) prepared a summary of city logistics management methods (Table 1).

Table 1
City Logistics management types

Management Methods	City Logistics Scheme
Traffic flow management	Constructing ring road, truck route, access control to cities, low emission zones, providing traffic information using ITS
Parking management	Truck only parking space, loading/unloading space on streets
Time management	Off-hour delivery, time windows for entering cities, time sharing between trucks and cars
Vehicle management	Low emission vehicles, optimization of vehicles routing and scheduling, road pricing, load factor control
Cooperative freight transport	Urban consolidation centers
Co-modal freight transport	Using passengers' cars or trams for delivery
Recognition	Recognition of green freight transport companies
Organization	Freight quality partnerships

2.2. City Logistics Measures through the Practical Knowledge

City logistics measures and systems are different for big, medium and small size cities, but it turns out that sharing information about experience with city logistics projects within the cities is a key to success. All over the word there are similar cities, which could share their ideas and help each other to receive the sustainability and liveability. It is crucial for international knowledge of city logistics, to know mistakes that were made and learn and get inspiration from them.
In 2002 the European Commission created a co-funding CIVITAS Initiative ('City-Vitality-Sustainability') for cities to network together and try to minimize the burden caused by urban freight transport and to create a cleaner and better place to live. Within the CIVITAS Initiative program, city-laboratories have been set up, were the various measures of sustainable transport have been deployed, tested and evaluated. The various number of measures were focused on different city logistics system like: alternative car use, clean fuels and vehicles, cycling and walking, logistics and goods distribution, mobility management, traffic management, public transport and access and parking management (civitas.eu., 2013). The CIVITAS initiative project has 5 phases, each phase included different cities and different implemented measures. Nowadays, the fifth phase named CIVITAS 2020 has continued, in which there are involved 17 cities and 3 living lab projects. Almost 70 cities participated of the CIVITAS initiative project during the first four phases. According to Rooijen (2014) and CIVITAS Elan final Evaluation report (2012) a lot of different measures were used in the EU cities, the most common were:

- an inner-city distribution center in order to create a new more efficient way of goods distribution,
- using an ITS to improve routes for good delivery by minimizing the number of routes or using real time communication to avoid congestion,
- using clean vehicles to minimize air pollution in the city.

Different cities involved in the CIVITAS project use different city logistics measures in order to adapt them in the most efficient way to the selected city. Next Table 2 represents success CIVITAS initiative project measures in cities across Europe (Rooijen, 2014).

Table 2
Successful CIVITAS projects

City	Measures and their implementation
Time windows in Iasi	Two times windows (one in the early morning and one in the afternoon) were implement in Iasi to optimize traffic flow in the city. Companies which use determinate time windows were awarded. The number of goods distribution vehicles decreased at peak hours leading to a better traffic throughput.
City distribution by Boat in Utrecht	In order to increase the use of water transport and to reduce the air emission, a zero-emissive electric boat was introduced to cover the supplies to a clients, shops, bar and

City	Measures and their implementation
	restaurant along the canal. The key result was the reducing of CO2 emissions by more than 38 tones.
Consolidation center and electric delivery vehicles in Bath	DHL company established consolidation center and use an electric vehicle for delivery into central Bath. New service was free for 15 months for business in Bath. Important result was decreasing number of trips to Bath and reducing CO2 and other pollutant emissions.
Low emission zone in Aalborg	The main idea was to create a low emission zones across the city to force distribution company to fleet renewal and use heavy duty vehicles complying with the latest standards.
Cargohopper in Utrecht	The electric Cargohopper is a multi-trailer 16 meter-long designed to fit into small street network of the city center. The multi-trailer has a capacity equivalent to 5 to 8 vans and delivers freight from a City Distribution Centre to the inner-city.

Source: (Rooijen, 2014)

During the CIVITAS initiative a lot of unsuccessful experiences were in the cities, but the important things are the suggestions and recommendations of how to avoid the same problems in futures projects. As it is turns out the most important conclusion from all projects across Europe is about the importance of partnerships between businesses, operators and authorities, which seems to be the key factor for the successful implementation of any measures (McDonald, et al. 2010). That's why the main innovation, which was outlined in the CIVITAS Elan final Evaluation report (2012) is the integration of measures from different policy fields into one comprehensive urban policy concept, for example stakeholder integration, institutional integration, policy integration, spatial integration, modal integration, cross-site integration and technological integration. Rooijen et. al. (2014) outlined that a very common urban freight logistics measure an urban consolidation center was planned during the project CIVITAS in a lot of towns, but almost none of the projects were successful. According to McDonald et. al. (2017) the main reason of failure was the insufficient partnership between the stakeholders. Taniguchi (2014) describes successful urban consolidation centers in the towns of Japan. Consolidation centers in Japan work on joint delivery systems, which means cooperation of freight carriers to jointly deliver and/or collect goods to and from customers using urban consolidation centers. The key reasons to create an urban consolidation center are the same in European countries and in Japan, like reducing the negative impact on the environment, reducing cost, number of vehicles and number of drivers. Author pointed out the different success factors for urban consolidation centers in Japan and in European countries due to different mentalities and customer habits. While the success factor according to Taniguchi for Japan's cities are good leadership, enthusiasm towards achieving goals and a business model to maintain joint delivery systems, in European countries the success factors are mind-set of balancing the economic vitality and the environment, core organization for management of urban consolidation centers and neutral carriers for operating the delivery. Of course, some of the factors are the same. For example, appropriate location for the urban consolidation center and sufficient use of consolidation center.

The objective of the article was to find out, among other things, the existing state of the city logistics under the conditions of the Czech Republic and to describe the Czech scientific publications related to the problem. Research of literature shows a lack of publication about this topic in the Czech Republic. Research in the Visegrád Group states (Czech Republic, Slovakia, Hungary and Poland) showed a lack of publication on urban logistics not only in the Czech Republic, but also in Slovakia and Hungary. In comparison to that of Poland, the problem of city logistics is devoted to several authors (Witkowski, Kiba-Janiak). However, the lack of any publication does not mean the complete absence of a city logistics project in the Czech Republic, for example the second biggest city in Czech Republic Brno was participating in the CIVITAS initiative project. The main objective of Brno's participation in CIVITAS ELAN was to improve the quality of public transport and to lead more people to use the services. Since the beginning of the project, Brno has equipped all ticket vending machines with a system that automatically alerts the control center to any defects, so it can be quickly resolved. In response to the aging population, Brno has introduced new low-floor minibuses that also allows easier access for wheelchair users. Brno also wanted to modernize its fleet of public transport to make it less polluting and more energy efficient. For example, in trams and trolleybuses, they installed a heating control system to optimize energy consumption (civitas.eu., 2013). Prague the main city of Czech Republic also participated in a city logistics project across Europe named SUGAR. SUGAR (Sustainable Urban Goods Logistics Achieved by Regional and Local Policies) aims to address the main city logistic problems like ineffective management of urban freight distribution, as a critical component of the overall urban transport system and a primary source of vehicle pollutant emissions. The main goal of the project is promoting the exchange, discussion and transfer of policy experience, knowledge and good practices through policy and planning levers in the field of urban freight management. The city of Prague's participation was about creating protected delivery zones, which aims to protect the historical center and create better conditions for flowing traffic. The project was achieved due to regulations based on the weight limit of trucks allowed to circulate in the historic center of Prague and setting parameters for delivery time windows in the city center. According to SUGAR (2011) the project was successful, the volume of trucks declined by 85% on the busiest routes, and traffic was transferred to more appropriate roads.

Dablanc (2007) pointed out two different, somewhat unusual measures in London and Barcelona, which helped to improve the city logistics situation. The first was about successful partnership between the logistics providers and the administration, where the two biggest carriers' organizations discuss the practical details of delivery organization with transport for London representatives on a regular basis. After a very conflicting discussion a compromise was achieved, for example, the level of the congestion pricing tax assigned to delivery trucks (£5 a day, the same as for car drivers). The second one described city logistics measures used in Barcelona, Spain, according to the author the administration of the city hire a freight motor squad to prevent illegal long-term parking. After this the leaner lines are being used for truck delivery, as zones for loading/unloading space during off peak hours and as parking in the night for residents.

3. Current State of the City Logistics in the Connection with the Postal Services

According to the European Commission, which is responsible for the efficient functioning and the legislature of postal services in Europe, postal services play a key role in an effective and dynamic market of businesses and EU citizens. The European Commission works on improving the quality of delivery and access to postal services. Official documents focused on postal services across Europe offers a lot of information about the significant role of postal services in the EU economy (the EU postal sector accounts for €91 billion or 0.72% of EU GDP), employment (about 1.2 million people were employed by universal postal service providers in 2013) and in e-commerce (the parcel sector is dynamically growing in terms of volume and plays an important role in the development of e-commerce). Over 6.4 billion items were shipped in 2011 (European Commission, 2011). But according to Dieke et al. (2013), between 2007 and 2011 the European letter post sector declined in terms of revenues and volume. Demand for traditional letter delivery has fallen significantly: since 2006, the aggregate mail volume declined by more than a quarter in advanced economies and more than halved for some posts. In recent years the decline in mail volume slowed to 4.2% in 2016 compared to 5.6% in 2015 (IPC, 2017). Another significant change in the postal services market is the large development of e-commerce, which has led to the changing of consumer behavior and growing demands for parcel delivery services. Worldwide people buy things online more than ever, Internet retail sales have risen 18% per year on average since 2006. In response, postal operators create clear and consistent strategies, looking to grow the parcels business and further enable e-commerce. Also posts operators are seeking growth in new business and geographical markets to diversify revenues and are focusing on cost control and innovation as competition heats up and customer needs evolve (IPC, 2017).
Furthermore, the postal services market has undergone another change, which was the full liberalization in 2012, after that changes in the national postal services providers have exposed the competitive pressure mainly on profitable markets such as the parcel delivery market. National postal operators in Europe reserved in the area of universal services for example letter mail and preserve the monopoly position in this market. However, it has become necessary to maintain a position in the growing parcel delivery market, where most of the competing companies apply the strategy of cream-skimming, i.e. offers its services only in the cities with the highest density and offers fast and frequent delivery through the distribution warehouses around the city. The situation has led to the fact that large number of trucks from different companies are daily circulating in Czech and European cities. The biggest issue is that the councils of the cities have no idea how many cars are going through the city every day and what impact it has on the environment and traffic situation in the cities. The situation can be symbolized with the scheme below:

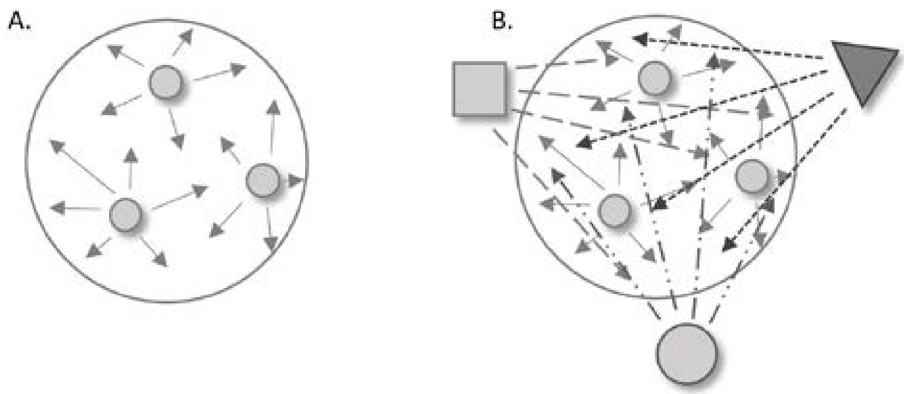

Fig. 2.
The supply chain situation in the city before then (A) and now (B)
Source: Author

Figure 2, Part A, illustrates the supply chain situation in the city before the e-commerce growth and liberalization, which means before the strong competition in the selected market, during this situation the national postal service provided the letter and parcel deliveries within the city. Now the situation has changed quite a bit (part B), the supplying cities arrange different transport companies from the distribution centre outside the city (triangle, rectangle and wheel), it leads to a bigger number of trucks in the city and chaos in city logistics, when transport companies in effort to achieve the greatest gain and take on a high competitive position offer more frequent transport by low loaded factor trucks. The e-commerce growth and the liberalization of the postal market consignments has caused in the cities the appearance of large number of private companies offering preferential parcel delivery services, which had lead to the need for changes to the national postal services provider in order to succeed in the new competitive market. The

European Commission's efforts to increase the efficiency of the postal sector, by opening the market to competition, has been accomplished. The are a lot of successful and efficient transport companies offers supply chain in the city, however it is looks like the side effect of liberalization and e-commerce growth was one big surprise for the cities and until now it is not clear how to solve this problem. The situation has persisted in many European cities since 2012 and it is one of the causes of such a wide interest in city logistics now. The main topic of this article is a suitable solution for the current situation particularly the inefficient position of national postal operators and unsustainable traffic in EU cities, especially in the Czech Republic. As was mentioned before, several authors dealing with the issue of city logistics perceive the lack of cooperation and communication between the private and public sector as the main cause of the failure of many projects in the field of city logistics. The scientific research and publications about this subject are focused on the possible ways how to ensure effective communication between two sides and force the private sector to respect the interests of single cities.

The main idea of the article lies in another view of the whole situation: why, in order to create sustainable city logistics in the cities, not directly cooperate with a more suitable partner? A partner who already has a network site, city-centre buildings, and transport facilities to meet the needs of customers primarily in the parcel delivery market (B2C or B2B) and will be willing to take into the consideration the requirements for sustainable urban development, particularly in the area of sustainable transport. It can be assumed, therefore, that a national postal operator, such as Czech Post, which is linked to the state (compensation for the provision of universal postal services) and for which, apart from private entities, constantly increasing profits at any price is not the main objective (due to historical development and the post-mortem position of the post office as a firm), could be more sophisticated and adapted to the underlying requirements on environmental, social and economic sustainability in cities.
